World's biggest copper mine	470	Ton Reed Gold Mines Co.	22
Cinderella Consolidated mine	247	Tonopah Extension Mining Co.	22
Cinnabar float, a placer, not lode	6	Union Con. Mining Co.	230
Flotation for	34	Utah Copper Co.	546
City Deep, Ltd., company report	301	Zinc Corporation	546
Civilization	131	Comparison of stoping methods at Calumet & Arizona mine	315
Claims, boundaries of mining	551	Compensation, Court decisions on	916
1, 9, and 12, in patent No. 835,120, infringed	515	In Montana	951
Clapp, H. B. Flotation at Florence-Goldfield mill	556	Complex ore treatment in the United States	879
Classifier, drag type	808	Compressed-air by falling water	212
Clay-workings, a residual lead deposit in Missouri	412	Haulage, cost of	862
Clevenger, G. H. and Morgan, Harry. Atmospheric decomposition of cyanide solutions	667	Pumping water with	221
Ditto	556	Uses of	30, 201
Clifton-Morenci district, Arizona, flotation in the	610	Comstock Lode, Nevada, progress	888
Mineralization of	598	Progress in 1915	261
Clyne, C. B. Stoddard mill—copper concentrator	468	Concentrate, cyaniding, flotation	610
Coal, burning, powdered	826	Produced at San mine, Korea	684
Consumption of United States per capita	751	Wet treatment of copper	41
Firing reverberatories at Garfield	26	Why ship?	389
In Colorado	163	Concentration and smelting of vanadium ore	54
Leasing in Alaska	283	At Garfield, Utah	742
Miners' wages in Colorado and Pennsylvania	585	At Miami	742
Mining in Alaska	160	Of molybdenum	332
Mining in 1915	98	Of tungsten in Korea	431
Powdered for sale	542	Of ores by flotation, Hoover's new book reviewed	129
Coal-tar as a flotation agent	505	Tables at Flat River, test between	336
Coast Copper Co., British Columbia	13	Concecnully and Ruby districts, Washington	525
Cobalt, notes on	503	Concrete dividers and guide in shafts	953
Cobalt, Ontario, flotation at	13	Laying in cold weather	516
Products, sulfur and power	527	Stringers in inclined shafts	507
Progress in deep development	372	Concreting a shaft	521
Result of labor investigation	647	Shafts in Amador, California	521
Coeur d'Alene, Idaho, mining in	751	The Sacramento shaft at Bisbee	88
Small mines	341	Condenser, Beyer barometric	874
Coffee district, California	282	Conditions in Mexico	155
Coghill, Will H. Molecular forces and flotation	701	Ditto	862
Coke production of United States	520	Congress of Human Engineering	707
Coke-oven by-products in 1915	701	Coning and quartering sampling	165
Colby, W. E. Extra-lateral right, shall it be abolished?	556	Convey Placer Mining Co., dredging results	361
Cole, David	556	Consolidated Arizona Smelting Co., company report	827
Arizona	560	Consolidated Gold Fields of South Africa	835
Ditto	588	Company report	757
Cole-Bergman	49	Consolidated Interstate-Callahan Mining Co., company report	477
Collins, George E. Elmore and flotation	267	Dividends	903
Colloids, definition of	217	Consolidated Mining & Smelting Co. of Canada, reduction works	207
Color of earth's surface	267	Consolidation of the Teanaway mines	501
Of porphyry or monzonite	217	Contact deposits, definition of	377
Colorado, coal output in 1915	285	Construction and operation of Nevada Packard mill	832
Mining in	713	Constructive aid for prospector	28
Tungsten in Boulder district	713	Continuous countercurrent decantation process, notes on	126
Uraninite in	958	Oratec machine	519
Colorado Metal Mining Association	279	Converters, basic-lined copper	561
And tungsten	898	Basic, who used the first?	920
Colorado Power Company	487	Cook, value of at survey or mining camps	357
Colorado School of Mines	487	Cook, Buckhorn mine, Nevada	720
Colorado Scientific Society and revision of mining law	411	Cooler for compressors	165
Columbia University	6	Coolley and Harz files at Dolphin	759
Comacaran mine, Salvador, cyanidation at the	411	Copper, analysis of new book	897
Ditto	220	And other exports	630
Company reports	178	At 33 cents	598
Amalgamated Zinc (De Bavays)	895	Companies and Allies' notes	358
American Smelting & Refining Co.	505	Concentrate, w. treatment	426

T. A. RICKARD, *Editor*

OIL PRODUCTION of the United States is estimated to be at the rate of 800,000 barrels daily, equal to 292,000,000 barrels per annum. In 1915 the total was 291,400,000 barrels, but the marketed production was only 267,400,000 barrels. At the present time there exists a good market for all grades of petroleum products.

A STATEMENT has been made, and widely published, that on account of European capital being unavailable to continue work at certain California mines, there are 1000 less miners employed in this State than formerly. While sundry prospecting operations depending on foreign capital may have been suspended or reduced, there has been a noteworthy increase in the number of men employed in re-opening old mines, starting new mills, besides an expansion of operations at antimony, chrome, copper, lead, magnesite, manganese, tungsten, and zinc mines throughout California. Such increases largely exceed suspensions. The Industrial Accident Commission reports that at mines, mills, quarries, smelters, dredges, and cement plants there are 13,000 men employed, and gains are continually being reported. A similar expansion is in progress in the West generally.

RUMORS are current on Wall Street that "a billion-dollar copper merger" is to be organized for the purpose of consolidating or combining, in a manner not described, all "the big copper mines of the West and Alaska." We believe this to be untrue, for no sound economic basis exists for such an agglomeration. The copper-company units are big enough. Some of them—like the Kennecott affair—are already more conducive to stock manipulation than to cheapness of operation. Any idea of controlling the price of the metal by restriction of output or domination of the market is preposterous, having in mind the two previous abortive efforts to do so. If the Secretan syndicate failed in 1899 when the world's copper production was only 476,000 metric tons, what chance of success is there now with an output of over 1,200,000 tons per annum? We assume that the talk is made in order to excite speculation.

WESTERN Australia, as a State in the Commonwealth, endeavors to assist mineral exploration by means of money grants, the erection of stamp-mills for treating small lots of ore, and by geological surveys. In the end, however, the best work is done by private and corporate enterprise. The latest phase of systematic prospecting is credited to the Sons of Gwalia, a mining

company that produces \$100,000 in gold monthly. This company is equipping parties to prospect for gold and other metals. The men are paid wages with a contingent interest in anything that they find. Something is needed to sustain the gold production of the Australian commonwealth, for a steady decline is reported officially. During the first quarter of the current year the yield from the six States was 404,260 ounces, as against 477,410 ounces during the same period of 1915 and 875,000 ounces ten years ago. Western Australia showed a decrease of 41,841, to 255,948 ounces, in the quarter mentioned. This compares with 460,000 ounces in the first quarter of 1906.

IMMIGRATION is increasing slightly. In December 1914, also in January and August 1915, the admissions were less than the departures, but in April 30,560 arrived as against 4082 that departed. In April 1914, before the War, the arrivals numbered 119,885 and the departures 22,801, a gain of 97,084. This question of immigration plays an important part in fixing the price of labor, especially on the Atlantic seaboard. During the 21 months preceding the War, 2,102,360 immigrant aliens were admitted to the United States and 538,850 departed; in the ensuing 21 months, 503,364 were admitted while 293,644 departed. Nobody can predict confidently what effect the War will have upon immigration; whether the work of reconstruction will find occupation for ex-soldiers, as well as the many women now so usefully employed, or whether the disintegration and penury of large masses of population will cause them to seek new opportunities on the American continent, and, if they do so, whether they will come to the United States, or to Canada and South America.

UNITED VERDE EXTENSION Mining Co., the shares of which have risen to \$30 from a par value of 50 cents, had many hard knocks before success was achieved. The company was organized in 1894, and early work on the claims at Jerome proved so futile that the promoter committed suicide. Later the Red Rock mine near Providence, also in Yavapai county, Arizona, was acquired without successful result, and relinquished. In 1902 the United Verde Extension Gold, Silver & Copper Mining Co. was re-organized into the company of the present name, and in 1912 another re-organization took place. The *Boston News Bureau* estimates that the high price of \$30 per share will just repay the principal to the old stockholders of 16 years record, without considering interest. In 1913 the mine had about one mile of underground openings, and showed "a little ore of 267

copper, 1 oz. silver, and \$3 gold on the 800-ft. level." At the end of 1915 the bonanza, an orebody 250 feet square of 17½% copper, was uncovered. The president of the company is Mr. James S. Douglas, the son of Mr. James Douglas, the distinguished president of Phelps, Dodge & Co., New York.

GODFREY M. HYAMS is the name of the stockholder who has brought suit in the United States court to restrain the sale of the Tamarack mine to the Calumet & Hecla company. He charges that in the proposed sale, the Calumet & Hecla is acting both as vendor and purchaser, because this company already owns 19,400 shares of Tamarack stock, nearly one-third of the total issued. Mr. Hyams claims that the property is worth \$6,000,000 instead of the \$3,563,486 offered by the Calumet & Hecla. This is not the first time that Mr. Hyams has blocked the financial schemes of the Michigan copper companies. By means of his scattered holdings of stock he has opposed nearly every important move made by the Calumet & Hecla company during recent years. His ownership in the Tamarack mine is 1300 shares, which would be worth, at the \$59 offered by the Calumet & Hecla, \$76,700. It is not evident what Mr. Hyams gains by so many law-suits; but he is not unique; in nearly every mining region a similar type of man exists, a consistent opponent of combination and organization. Some people love to thwart others; they are born cantankerous. Others engage in battle to defend the down-trodden, for example, minority shareholders. We do not know to which category Mr. Hyams belongs.

TUNGSTEN is quoted at \$30 per unit and France is reported to be buying the metal. The following list of buyers and manufacturers of ferro-tungsten may prove useful to some of our readers: in Pennsylvania, the Primus Chemical Company, at Primus; the Vanadium-Alloys Steel Company and the Manhattan Reduction Company, both at Latrobe; the York Metals and Alloys Company, at York; the Bethlehem Steel Company, at South Bethlehem; the Crucible Steel Company of America, at Pittsburg; the Midvale Steel Company, at Philadelphia; and the Eirth-Sterling Steel Company, at McKeesport; at New York is the Goldschmidt Thermit Company, at 120 Broadway. Among brokers dealing in tungsten ores are the Foote Mineral Company, at Philadelphia; E. P. Earle, Charles Hardy, and Arthur Seligman at New York. Some of the steel companies buy ore as well as ferro-tungsten. The recent recession in price is due primarily to the decreased business in munitions. When the placing of contracts for munitions was at its height, there was a heavy shortage of high-speed tool-steel, so that an inordinate demand for ferro-tungsten was incited. Just now new contracts for munitions are few, so that some manufacturers find that they had overbought tool-steel. Fresh foreign business is pending and a strengthening of the market is anticipated, but the boom prices of a few months ago must be considered a thing of the past. Those are wise that base the

success of their operations on a price nearer that existing before the War than even the present reduced quotation.

LEAD is produced in large quantity by three States, Missouri, Idaho, and Utah. Their production in 1915 was 195,634 tons, 160,680 tons, and 106,105 tons, respectively. Colorado was a poor fourth with 32,352 tons. The great bulk of Missouri's output comes from the south-eastern part of the State, where a half-dozen companies work on 3 to 4% disseminated ore. The characteristic of this district is that lead alone, without zinc, is produced. Idaho's production comes from the lead-silver-zinc ores of the Coeur d'Alene. During some years the output of this region has exceeded that of Missouri. Utah's production has risen steadily during recent years. The silver-lead ores of Park City and Bingham have been the principal source. To these must be added the mixed ores of the Tintic district. From foreign ore and bullion, only 43,029 tons of lead was refined in the United States last year. This compares with 94,984 tons in 1911; the bulk of it coming from Mexico. The production of lead from domestic ores last year reached the total of 537,012 tons, comparing with 389,211 tons in 1910, a gradual growth. The American Smelting & Refining Co., it should be recalled, produces about 50% of the country's total output of lead. Next to the United States, the important lead-producing countries of the world are Spain and Australia.

DISCUSSION this week starts with a reminiscence from Mr. R. C. Canby, who recounts an unsuccessful effort to use cyanidation two years before the MacArthur-Forrest process was made known. Mr. Canby was one of the principal experts in the Minerals Separation-Miami case; hence his last remark is apropos. Our friend Mr. F. H. Mason contributes some notes on the tempering of drill-steel, dealing more particularly with the physics of steel as elucidated by Osmond, and indicating the part played by quenching. From Chile we have a letter signed by Mr. Mark R. Lamb, the representative, at Santiago, of an important machinery manufacturer. He describes a personal experience in the re-torting of quicksilver, with due consideration for the possible use of the flotation process. Mr. C. O'Brien, an experienced mill-man, lately at Kirkland Lake, breaks a lance with a recent contributor, Mr. Peckham, in regard to a special phase of cyanidation. His argument is that the continuous counter-current-decantation system, which he mercifully abbreviates to 'C. C. D.', does not lose efficiency by addition of high-grade ore, and that any failure to obtain the best results at Comacaran was due to an imperfect flow-sheet. Mr. H. E. Nicholls writes from London to approve Mr. Corey C. Brayton's recent article on a method of drilling alluvium and draws attention to an earlier article by himself on the same subject. Finally, Mr. Edgar Hall, one of our best friends in Australia, contributes bits of information that will be appreciated by our readers as coming from a man of varied experience.

A Delicate Subject

We note that the *Financial News*, of London, and the *Engineering & Mining Journal*, of New York, have got into a controversy on the subject of 'Americanizing British Mines,' referring thereby to the employment of American engineers by British companies. The subject has also engaged the attention of the *Mining Journal*, of London. These journalistic amenities were started by an intemperate and crudely phrased editorial in the *Financial News*, which is a low-grade paper not to be confused with the *Financial Times*, published at the same centre. The article in the *News* was followed by a number of letters showing much prejudice, and, we think, a regrettably provincial attitude. Some of the feeling that found vent in this ill-tempered outburst is the product of the War. At this time of great conflict, when half the world is under arms, the individual becomes touchy, if not belligerent, on international affairs. Civilization has become a 'rough-house.' Our most cherished beliefs and our dearest sentiments are being wounded during this terrible turmoil; we are on edge; even the best of friends wax warm over the issues at stake. No wonder then that the politenesses of life are in danger and we say things that in quieter normal days would surprise us. The controversy to which we refer is a sign of the times. Our own attitude in the matter will be readily surmised by our readers. In professional matters we are Mercurio, having no sympathy with either the Capulets or the Montagues that attempt to stir jealousy or ill feeling among English-speaking members of a broad-gauge profession. The American engineer employed by British companies has been selected on account of his ability; so long as he, in turn, selects his assistants and subordinates for the same reason, not on account of the place of their origin, he does what is eminently fit and proper. When, however, a junior is picked, not on account of fitness for the work in hand, but because he is a fellow-countryman, a brother-in-law, or a Baptist, the senior is not dealing fairly with his employer, whether that employer be a board of directors or the shareholders in a company. This error has been committed, and usually it has brought its logical punishment in the loss of confidence and the lowering of efficiency. We grant that some second-class Americans have gone to London, and have fared ill there; also a number of poor specimens went to South Africa, where they did not remain long; but only an ignorant man would deny the splendid service given to the British mining industry by such men as Gardner Williams, Hennen Jennings, George Webber, Frank L. Bosqui, W. L. Homgild, R. Gilman Brown, H. C. Hoover, W. J. Loring, and R. M. Raymond. We agree with our contemporary in New York that if the arts of mining and metallurgy, as applied to Great Britain's overseas dominions and her investments elsewhere, be unsatisfactory, it arises largely from the failure to appreciate the fact that the British empire was extended in the footsteps of the mineral explorer and that British trade followed, not the flag, but the

pick. Mining education also has received no such support as it deserves at the metropolis of an empire the development of which was based largely on the exploitation of mineral wealth. The Royal School of Mines, thanks to the help, among others, of an American, Mr. Hennen Jennings, has been saved from extinction, it is true, but it is absurd to consider its present status as satisfactory or its endowment as adequate for the one central mining college of a people whose flag flies over such mineral regions as Australia, South Africa, and India. Fortunately, Canada has taken care of herself in this regard. So that if this controversy is remembered, we hope that it will be to emphasize the fact that the mining industry needs efficient men, and will get them wherever it can, particularly from among those speaking the language of its Anglo-American operators and sharing with them the great traditions of fair play, honorable sport, and good government.

The Mexican Crisis

A state of war exists between the United States and Mexico, but at the time of this writing the fact had not yet been recognized officially. When, on June 17, the President called the State militia to duty on the Mexican border and followed this step by the publication, on June 20, of a note to the *de facto* government of Mexico, it was assumed that at last the policy of watchful waiting had been found unavailing; that a policy of *mañana* had given place to one of *hoy*. The public generally supposed that military intervention, as a preliminary to restoring order in Mexico, was assured and that the six years of Mexican misrule was to end in measures similar to the ones found effective in Cuba and the Philippine islands. Those who had property interests in Mexico may have been pardoned for supposing that better days were in store for them. But on June 22 Secretary Lansing sent a memorandum to the diplomatic representatives of the Central and South American republics in which he stated that the object of the United States government was "not intervention in Mexican affairs * * * but the defence of American territory from further invasion by bands of armed Mexicans, protection of American citizens and property along the boundary from outrages committed by such bandits, and the prevention of future depredations by force of arms against the marauders infesting this region and against a government which is encouraging and aiding them in their activities." We quote at length because this statement is one likely to have been overlooked or subordinated to the diplomatic note published two days earlier. No reference is made by Mr. Lansing to Americans or American property in the interior of Mexico; he mentions only such as were suffering from the banditry along the border. However, while the statement begins by disclaiming intervention, it ends in the promise of using the force of arms "against a government which is encouraging and aiding" such activities. This pointed directly at Señor Venustiano Carranza and his associates; and

as these gentlemen constitute the *de facto* government of Mexico, recognized as such by the United States, it gave warrant for the belief that war between the United States and Mexico would ensue, if the unsavory condition of affairs was allowed to persist. The truth concerning the Carranza government's attitude toward the brigands, of whom Villa was only one, and the attitude of that government toward American life and property, whether within Mexico or on the border, is made perfectly clear in the note of June 20. Indeed, that note indicates what bad faith Carranza has shown to the United States, the government of which stretched a point in recognizing him, in the hope that the recognition would strengthen his hands in the work of pacification. It shows that the effort made by General John J. Pershing's expedition to catch Villa and his followers received no assistance from the Mexican local or federal authorities, that other notorious bandits have holmobbled with Carranza's officers, and that the Mexican government has taken no steps to prevent repetitions of the Brownsville and Columbus raids. One weak point is the evidence that the punitive expedition was not sanctioned by Carranza, although on this the note is not clear, for in one place it is said that the expedition crossed the border under "the repudiated agreement of March 10-13" and in another place "it is admitted that American troops have crossed the international boundary in hot pursuit of the Columbus raiders and without notice to or the consent of your government." Again, the note certifies to the fact that the victims of the Santa Ysabel massacre carried safe-conducts issued by the local authorities. In that horrible affair, as in the Columbus raid, the Carranza officials took no steps whatever to obstruct Villa in the perpetration of crime. Then came General Jacinto B. Trevino's order, subsequently endorsed by General Alvaro Obregon, the Mexican Secretary of War, forbidding General Pershing to make any movement of troops except northward, that is, a retirement. General Pershing ignored this order; in consequence, on June 21, troops C and H of the Tenth (negro) cavalry came in conflict with a commando under General Felix Gomez, under circumstances not yet clearly disclosed, but with the result that several were killed on both sides and 17 American troopers were made prisoner. Thereupon, on June 24, the Mexican government coolly informed the American government that the attack at Carrizal was due to a disregard of Trevino's order to Pershing. To this our government replied by demanding "the immediate release of the prisoners taken in the encounter at Carrizal," with a peremptory request for an early statement as to the course of action the Mexican government proposed to take. Obviously, Mr. Wilson is loath to commit this country to war; equally obvious is the fact that Señor Carranza shrinks from starting definite hostilities; but it looks as if Villa's expectation would be fulfilled and his depredations force Carranza either to war with the United States or out of office. That is the position today. The logic of events will prove too strong for either side. At this time of writing it appears to us that war, followed by military

occupation and political intervention, in order to ensure orderly government, is inevitable.

Mining Education

This is a subject often discussed in the MINING AND SCIENTIFIC PRESS, and we offer no apology therefor. Education is one of the fundamental problems of the orderly way of living called civilization and it must interest every man, both as a son and a father. In this issue we publish a thoughtful article by Mr. F. Lynwood Garrison, himself the product of a generous culture and a wide experience. He comments upon the fact that an art is best taught in the place where it flourishes, while mining schools are usually situated far from the mining regions. As to that, it is natural that schools should flourish near centres of population. Freiberg gave this country more good analysts and chemists than mining engineers. It is the old question, whether it is better to bring the fuel to the mine or transport the ore to the fuel-supply. Colleges and schools need the support of a large population even more than the stimulation of an environment congenial to a particular branch of study. The reason why the small college in a small Western town spoils good ranchmen in the vain effort to make mining engineers is that it cannot give its students such a range of instruction as is within the scope of a central university. We agree with Mr. Garrison that a mining engineer requires a broad education; he needs all the education he can get in order to cope with the wide variety of men and conditions he has to face during his professional career. Indeed, it is a career to test character. Next, Mr. Garrison refers to the part that the engineer plays in the life of the community. He is a 'super,' instead of a principal actor. The profession will never reach its proper status until the members of it recognize their duties as citizens and demand a larger voice in community affairs. Most of us think that the lawyer plays too great a part and too many of them. He does so not only because his occupation gives him practice in public speaking and writing, but because his cultural training is such as to fit him for leadership in politics and government. The broad or cultural education for which Mr. Garrison pleads as a preparation for the mining profession is exactly the training that makes not only a capable engineer but a useful citizen. That should be the aim of a democracy or any other enlightened method of government. Lacking a general preparation for life, trained to be a specialist, prepared to pursue the elusive shekel, the mining engineer is likely to find his opportunities circumscribed. To practise as a specialist he must be where his specialty is in demand; to pursue the shekel successfully he must have a modicum of *minas*; for money makes money. Not many engineers are engaged in the particular branch of science for which they originally made some special preparation; most of us did the work that was first offered, and found our aptitudes after a good deal of 'knocking about' amid the fortuities of circumstance.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Discovery of Cyanidation

The Editor:

Sir—I have read with interest Mr. John S. MacArthur's article on this subject in your issue of June 10. It is, however, not the original discovery or use of cyanide as a solvent of gold and silver from ores that Mr. MacArthur describes. F. M. Endlich and Nicholas Muhlenberg filed a caveat in the U. S. Patent Office for a process utilizing the solvent action of potassium cyanide to extract by leaching gold and silver from their ores. Dr. Endlich was the general manager of the Sierra Grande, and associated mines, at Lake Valley, New Mexico.

In 1885 I went to Lake Valley to witness a trial-run of the Russell hyposulphite process in the interest of the directors of those mining companies. E. H. Russell was himself in charge of the Russell process plant, which had been built as an annex to the Boss continuous process pan-amalgamation mill. The extraction by the Russell process upon the 20-mesh ore was only about 72%. I was, therefore, persuaded to try Endlich's cyanide process. The cost of the cyanide, however, as compared with that of the "hypos" was such, and the improvement in extraction, if any, so slight, upon the 20-mesh ore, that Endlich's cyanide process was not substituted for the Russell process. This was before the days of fine grinding.

This trial of the Endlich and Muhlenberg process that I made in the Russell-process hyposulphite-leaching plant of the Sierra Grande company at Lake Valley, New Mexico, some two years prior to the experiments referred to in Mr. MacArthur's article, I believe to have been the first application of cyanidation.

I have always considered, however, that it was the very two things which Mr. MacArthur rather minimizes in his article that actually made the cyanide process economically possible; these were the effectiveness of the dilute solutions and the precipitation by zinc. I agree, however, most fully with Mr. MacArthur when he says: "Cyanide does this (dissolves gold from ores and holds it in solution) and so far as I know is the only solvent that can do it. This is the real essence of the invention—the matter of weak or strong solutions follows as a matter of chemical (and commercial) economies."

Such an expression from Mr. MacArthur is extremely apropos in the present flotation litigation, in which it is contended, against the pretensions of the patentees of the minute quantity of "oil," that it is the flotation by

use of such reagents that is the "real essence" of the process the matter of more or less of the reagent being "a matter of chemical and commercial economies."

R. C. CANBY.

Wallingford, Conn., June 15.

Tempering Drill-Steel

The Editor:

Sir—In your issue of May 27, you publish a drill-manufacturer's recipe of 7 lb. blue vitriol and 4 lb. sal-ammoniac dissolved in 15 gallons of soft water for tempering drill-steel. From the earliest days of steel to the present time, blacksmiths have had their pet recipes for tempering steel, and often have guarded the secrecy of them with a persistency worthy of a better cause. In the 16th century some very quaint recipes were published, as, for instance:* "Take the blood of a man XXX years of age, and of a sanguine complexion, being of a merry nature and pleasant, and quench the steel in it." I don't say these recipes have no merit; they have, but, as what merit they possess lies in the varying thermal conductivities of the liquids, the end may be attained by less lung-irritating or typhoid-inducing fluids than those mentioned above.

Osmond, the French metallurgist, has shown that iron cools from a bright-red heat at an almost even rate until it reaches a temperature of 858° C., when the cooling is arrested, and it takes 26 seconds for the temperature to drop through an interval that had previously taken and subsequently took only 6 seconds. With low-carbon steel there are two points of arrest, at about 720° and 650°, respectively, while with high-carbon steel these two points seem to be merged into one, and there is a long period of rest amounting in the case of 1.25% carbon steel to 76 seconds while the temperature dropped from 685° to 665°, while previously it had fallen through a like number of degrees in 12 seconds. Steels containing 20% manganese or 10% tungsten, on the other hand, were found to cool at a uniform rate without any marked period of arrest. Osmond found that if ordinary steel was heated and quenched rapidly before it reached this period of arrest, or the critical temperature, as he called it, it was hard, but if quenched after the critical temperature it was soft. High manganese and tungsten steels, which showed no critical temperature, are hard when cold whether they are quenched or allowed to cool slowly.

*English translation of "Rechter Gebrauch d. Alchemie!"

From these experiments Osmond argued that at the critical temperature there is a re-arrangement of the molecules, and in the case of steel there is a re-arrangement of both iron and carbon molecules, and that while before the critical temperature the carbon is dissolved in the iron, after that point it exists as a carbide of iron. The point, then, in hardening steel, is to cool the metal before the molecular change takes place, and while the carbon is dissolved in, and gives hardness to, the steel. Steels that pass rapidly from the one state to the other require a quenching fluid of high thermal conductivity, in order that the molecular change shall not take place during the process of quenching. In the tempering, or 'letting down,' as the blacksmiths often call it, it is often desirable that the quenching operation shall be prolonged, so that the carbon may be judiciously mixed in the two forms, and in this case a quenching fluid of low thermal conductivity is desirable.

San Diego, June 7.

Flotation for Cinnabar

The Editor:

Sir—The communication from Mr. E. M. Hamilton on this subject in your issue of April 15 makes it seem probable that our experiments at Punitaqui (Chile) will be of interest.

We are retorting quicksilver ores containing from 0.4% up, in retorts varying from 12 to 24 in. diameter. The recovery on the low-grade material is much lower than on the ore above 3%. The ores contain the quicksilver in four distinct forms: cinnabar is the most important; a red powder supposed to be an oxide is next in importance, followed by native quicksilver and a tetrahedrite containing 10% quicksilver in the pure mineral.

When the price of quicksilver drops to \$30 our problem will be to choose between a McDougall furnace and flotation. Flotation gives a high extraction. The oxidized ore simply cannot be wetted, and the cinnabar is little better. The tetrahedrite would concentrate well on tables and also gives excellent results with oil. The only tests that show a loss of native quicksilver with flotation are on minerals very poor in sulphides. The ore is mainly quartz and a soft gangue.

So far, I have decided that retorting is much the cheaper treatment, even assuming a perfect extraction by flotation. Even in the present slow and fuel-wasting manner, the retorting is extremely cheap—much cheaper than the crushing. The cinnabar sometimes occurs massive or in 20 mesh crystals, but 90% of it is in the form of finely disseminated particles in the quartz. This would mean fine grinding, which would cost more than roasting, and the plant would be much more expensive. At present we are roasting three tons with a ton of wood worth \$3. With a McDougall we could roast 10 tons with the same fuel. This does not mean, of course, that we shall discontinue our tests, in the hope of being able to

treat the big waste-dumps in the most profitable way.

Our greatest loss at present is in the vapor that cannot be disentangled from the ore, after the major portion has been dragged out by the water-vapor. In the large retorts containing 600 lb. of ore with a content of 24 lb. of quicksilver, it will be easily seen that half the metal can remain in the interstices of the ore, whatever the temperature. When coarse ore is being treated, it is not difficult to make this vapor move forward into the condensers by squirting about a gallon of water upon the red-hot ore, but with fine, this plan does not give the desired result.

MARK R. LAMB.

Santiago, Chile, May 16.

Cyanidation at the Comacaran Mine, Salvador

The Editor:

Sir—In studying the article by Mr. A. B. Peckham appearing in your issue of April 29, one cannot help but note the difference in practice between the continuous counter-current decantation process as used there and in such localities as Porcupine, where it is recognized as a success.

The flow-sheet presents something unusual in the re-grinding closed circuit. Why the crushed ore from the stamps is sent to a Dorr duplex classifier, the overflow going to thickeners, the heads to a simplex classifier, by-passing the tube-mills, is difficult to understand. The flow-sheet shows nothing entering the tubes but something coming out. This must be a mistake in the diagram. However, more information is gleaned by reading under the heading 'Tube-milling and Classification.' A suggestion will not be amiss. Even a casual analysis of the ore and screen tests would make the article of greater value to metallurgists.

Looking over the 'Slime treatment,' five agitators are in use, two mechanical-air and three Pachucas. The size of these agitators is important but it is not mentioned. Experience all over the world proves that intermittent or charge agitation is not any better, if as good as continuous agitation. The first cost of the latter, and certainly the operation, is less. The agitation would be disclosed by analyses and screen-tests, seeing that a 55c. loss of 'insoluble' metal is acknowledged.

'Continuous Decantation.' To one accustomed to the simple and efficient manner of regulating the passage of the pulp and the counter-current, so that it becomes almost automatic, the reason for juggling the solutions is not readily apparent. In the 'C. C. D.' process, the distinction between values of the dry slime and solution are of paramount importance, especially at the dewatering end.

'The pulp from the Pachucas, which contains about \$3.50 together with the clear overflow of battery-solution from thickener No. 1, which contains \$1, goes to thickener No. 4. The clear overflow from No. 4 to the rich-solution tank, which assays about \$1.75 per ton.'

"The pulp from the Pachucas, which assays about \$3.50." Is this value in dry slime alone? This is quoted under 'Slime treatment' as 25% or three to one. "The clear overflow of battery-solution contains \$1." Exception must be taken to this misnomer. It is not battery-solution, but the overflow from the closed grinding-circuit, as the flow-sheet shows the Dorr duplex classifier to be the only outlet to thickener No. 1. Therefore \$1 is the value of extraction, dissolved value, in the closed grinding-circuit, consisting of stamps, two classifiers, and five tubes. This seems strange. Practice today is considered poor if it does not dissolve at least 50%.

Precipitation of solution, value \$1.75, cannot be said to be the best practice, when so much richer solution can be precipitated at the same cost, greatly curtailing the work in the refinery.

The flow-sheet does not show the overflow of battery solution from thickener No. 1 going directly, as stated, to thickener No. 4. It passes through settler *D*. What function this performs is not stated.

Coming to 'Tailing.' One notes a 10c. loss as dissolved value. This is certainly good work; credit must be given and taken. The 'insoluble' metal loss is 55c. In the tables, under 'Solution Assays,' 'Tailing thickener 7,' the word 'undissolved' is used. There is a vast difference between 'undissolved' and 'insoluble,' in metallurgy.

The rakes of the thickeners are said to have caused trouble by sticking. No doubt, some of us have had the great pleasure of emptying and cleaning out thickeners. The chief and really only cause of that is abuse. All sizes of thickeners, like all machinery, are calculated to do so much work, and no more. When they are overloaded, like the mule, they buck and stick, or the central shaft turns into a corkscrew. In this case the Frenier pump, a pulsator pump, might have been the trouble. In time, a large amount of hard pulp is likely to have accumulated on the bottom of the tank. The raising of the rakes gave a little more grade.

A difference of opinion arises concerning the disadvantages mentioned. No necessity exists for precipitating a large amount of low-grade solution. The reverse is more nearly true. For obvious reasons the highest grade of precipitate is desired, principally to save zinc and refinery work. The precipitation will regulate the barren solution. All that is really desired is enough for the counter-current. The water-wash will balance the amount of moisture sent to the dump. It is not obvious why barren solution is fed to thickeners No. 5 and 6; one should be sufficient. A paramount feature of the decantation end is a steady counter-current and a general equilibrium. But under 'Sand treatment,' barren solution is used for 'baths.' This is hardly fair to the 'C. C. D.' This explains the large amount of barren solution. The process is only meant to take care of itself, not two processes. (2). The impracticability of the process with an ore that resists settling. This is vague. An ore that resists settling may still settle sufficiently to permit good work. An ore that will not settle has few

charms for the 'C. C. D.' process, as should have been considered in the beginning. The Dorr people are frank in this matter. They make all their calculations on 50% moisture. So this cannot, again, be called a disadvantage. (3). The C. C. D. process is not thrown out of adjustment, any more than any other process, by a sudden rush of rich ore. Of course, a higher tailing may result. This is not a metallurgical difficulty, but a mining difficulty. If the mill-heads are doubled it is not necessary to double the amount of barren solution, nor use more water, nor is it sound metallurgy to say the tailing-loss will double. What is the grinding-circuit doing at this time? Is it dying of *ennui* or a devotee of *mañana*? (4). A large amount of water is not used in the C. C. D. process, only just enough to make up for the amount of moisture sent to the dump. The process is continuous and therefore re-uses all the water, solution, etc. But, if as said, water is scarce, precautions should be taken at the beginning, and something like an Oliver filter installed to save as much moisture as possible.

Without exaggeration, it can be said, that the continuous counter-current decantation process has come into the field of metallurgy with less trouble and more practicability than any other process. It is just as amenable to the treatment of high-grade as of low-grade ores, both gold and silver, and is being installed to treat highly complex ores. In the beginning the metallurgy and the plant should conform to the highest grade of ore in the mine, then it is easy to take care of the lower grades of ore. Its flexibility is unequaled by any process as the four different types above. It has redeemed decantation.

Reviewing the mechanical side of the plant: With the large experience before us today, why install stamps? Let us make a short comparison with a ball-mill. The Hardinge conical ball-mill is in general use. A 6-ft. Hardinge will do the work of 15 stamps; it is cheaper in first cost, mill to mill; takes up considerably less space, consequently less building; less weight; less foundation; uses less power; crushes ore for less per ton than stamps; not half the trouble and work for the millmen; is not any more difficult to transport on mule-back, if as troublesome, when you figure heavy stems; the putting together is not more difficult than batteries; any kind of crushing can be done to suit conditions; amalgamation can be performed, if desired, with less trouble and space. So, really, what advantage do stamps have today?

The use of Frenier pumps, or pulsators, is new in the C. C. D. and it is doubtful if they can be recommended. No one would use them after having tried the cheap easy running diaphragm pump.

The many experiments with tube-mills in South Africa proved that the 20-ft. mill was not any better than the 16-ft. mill, if as good. Neither crushing nor re-grinding takes place in the last four feet, so of what use is it? Any U. S. machinery is just as good as Krupp's.

C. O'BRIEN.

Berkeley, June 9.

Prospecting Before Dredging

The Editor:

Sir—My attention has been drawn to the article on this subject appearing in your issue of April 29. The author refers to a new method of drilling by driving pipes, as used extensively by him. The method is one which was adopted by me in the Malay States as long ago as 1903 and was the subject of a short paper read before the Institution of Mining and Metallurgy, London, and incorporated in the transactions of 1904-1905.

I have employed this system with equal success in northern Nigeria; given suitable conditions, it is without doubt not only the cheapest but also one of the most reliable methods of testing alluvial deposits. My own experience is fully borne out by the figures given by Mr. Brayton in his very interesting article.

London, June 2.

H. E. NICHOLLS.

Useful Notes

The Editor:

Sir—In one of your recent issues you refer, as you have often done previously, to the waste of mining information owing to so much experience passing unrecorded. May I contribute a little of my experience in some matters touched upon in various articles in your issues of January and February, which have just reached me?

(1) American Machinery Exports. Among the important points necessary for exporters, I think that of insurance has been omitted. Next to having the articles properly packed, their insurance during transit is of the most importance to the buyer. It is not enough to insure the goods for the amount of the invoice; sufficient must be added to cover freight and other outgoings that the purchaser must pay, and often in advance. Insurance companies recognize this, and it is customary to increase cost and charges by 10% to cover further possible losses to the purchaser (through delays or changes of price incidental to duplication of the article lost). This does not appear to be understood by some American manufacturers.

Some years ago I bought a machine direct from a large American firm, one that advertises largely in all the technical papers and inundates members of technical societies with its literature. I instructed them to pay freight and insurance, and our London bankers paid them cash on shipment. The vessel soon after went to the bottom with our machine on board. When we went to collect the insurance we discovered that the policy covered only the cost of the machine at the maker's works. Result: we lost freight and other charges amounting to \$150, and resolved to buy nothing more from that firm, if we could help it.

(2) Prohibition. This village, of about 600 inhabitants and solely dependent on the mine, has no hotel or licensed house. For several years the land was held so that the owners' opposition was sufficient, later the ap-

plication for license was defeated by direct voting, under a local-option clause in the State Licensing Acts. The mine worked continuously from May 1893 to the outbreak of the War, a period of over 21 years. The depth attained is 500 ft. vertical; the orebodies are isolated lenses; the ground is heavy in general, and in places very bad. Only one fatality occurred during the 21 years: a fitter, sent below to repair a leaky pipe, looked down the shaft and was struck by a descending cage. Only one broken limb occurred: to a miner, attempting to light a cigarette when in a moving cage, whose projecting elbow struck a landing. No other accident, at mine or smelter, to any workman, could be called serious. No shift was ever lost owing to drunkenness, and no delay ever occurred at the furnaces owing to absence of men through drink. There were no St. Mondays. No other Australian mining town has such a record. We did not escape 'sly' grog-shops, but judging by our experience, the harm done by drinking on the sly is small compared with that of even one well-conducted open and publicly-licensed hotel.

(3) Early Ball-mills. At the Sunny Corner mine, in N. S. W., when I went there in 1887, there was a ball-mill procured, I believe, from San Francisco. It was then idle. I got it going and used it for crushing quartz for making silica bricks. It did excellent work.

(4) Nodulizing. At the same Sunny Corner mine, in 1888, I treated a large quantity of sulphide ore 'fines' in exactly the way described in your issue of February 12, as now practised at the Braden mine, only we did not call it 'nodulizing.' We used a revolving calciner, got about the same reduction in sulphur content, and the same red-hot nodules of varying size, and treated them very successfully in blast-furnaces, apparently just like the people at Braden. Again, at Silverspur we have a small sinter-plant for fine, which we used for some time, like that described at the Braden, only our boxes, though of the same width, and using similar grate-bars and down-draft, are much shorter. The results were the same and the sintered material worked well in the furnace.

EDGAR HALL.

Silverspur, Queensland, April 20.

THE Russian *ruble* is equal to \$0.5145673 United States currency. At the present time Russian exchange is quoted at \$0.3075, the decrease since 1913 being as follows: to 51.50c. in 1913, 51c. in the first part of 1914, 42c. in the second part, 29.75c. in 1915, and 29.31c. to June 13, 1916. Although the *ruble* has declined about 40% abroad, its purchasing power in Russia is more nearly holding its own, advances and decreases in prices of commodities being due chiefly to changes in supply and demand.

TUNGSTEN ORE (wolframite) concentrated at the Wasp No. 2 gold mine in South Dakota since early in 1916 totaled 1800 tons, averaging 1.08% tungstic tri-oxide (WO₃). The tailing assayed 0.13%, giving a recovery of 88%. Concentrate averaged 50 per cent.

Mining Education

By T. Lynwood Garrison

IT might naturally be supposed that the mining engineering profession would be largely recruited from boys who have grown up in communities associated in one way or another with the mining industry. While, of course, many such boys drift into it by opportunity or desire, it is a notable fact that very many of our distinguished mining engineers of today were born and reared in great cities remote from everything appertaining to mines, minerals, or geology. Similarly some, if not a majority, of our great mining schools have had their origin and now flourish in large centres of industry and population in no way directly related or connected with the mining industry.

A student in every other branch of engineering may without difficulty find in all large cities practical applications of most of the technical subjects with which he must familiarize himself, but the mining student must needs go far afield, often to considerable expense, and seldom has the opportunity of seeing what he learns in the class-room put into immediate practical use. This is an unfortunate condition and a serious handicap to the students, for an art is best taught in the atmosphere and environment in which it flourishes. Probably the most ideal and certainly the most famous mining school in the world is that at Freiberg in Saxony, situated on the northern flank of the Erzgebirge, a mountainous district famous for its mines since the Middle Ages. Indeed the old Saxon Mining Academy may justly claim to have been the mother and model of our American mining schools; the writings of its professors, such as Plattner, Von Cotta, Rittenger, Beck, and Stelzner were and still are among the classics of the profession. And although its glories have departed with the closing-down of most of the neighboring mines and the rise of institutions better qualified to teach the Anglo-Saxon, the Royal Saxon Mining Academy in my student days was a name to conjure with and offered its students an excellent technical training both theoretical and practical. Like most German universities, the social atmosphere of the place, however, was coarse and degenerate, sometimes demoralizing and often disgusting to American and English boys reared in refined and cultured homes where the laws of God and the moral precepts of man had been taught and respected.

There has doubtless been a great advance in the efficiency of our American mining schools in the last twenty years, but at the same time there seems to have been a needless duplication of effort that has tended to crowd a profession already overstocked with varying degrees of talent. Some of our Western universities have established mining schools, and mining schools as such have been started in Western towns simply because they hap-

pen to be relatively near mining districts. I once heard a mine manager say that as far as he could see the practical result of most of these schools was to spoil good ranchmen and make mighty poor engineers. This brings me back to my original thesis, that a mining engineer should above all else be a broadly educated man and that such a foundation may be best obtained as the result of a general university training. I doubt if any profession subjects its members to tests of character so severe and so prolonged as does that of the mining engineer. Consider for a moment how often he is placed in places remote from restraining influences, where he cannot seek advice of his elders or benefit from the stimulating moral control of home and family. In the absence of these checks a man must fall back upon his own cultural and mental resources, his books, his pen, and a love of Nature, into which the educated man sees so much deeper than one who has not been taught. A mining engineer often finds himself in situations so absolutely detached and foreign to the life he has been accustomed to, that it becomes a serious test of character if he has no diversions save his employment and the often frivolous pastimes of his companions. It cannot be disputed that a too complete absorption in one's work is bad both for the man and the job, hence it is highly important that the mind for short periods should be completely detached and interested in something wholly unconnected with the engineer's daily occupation. Under such conditions the broadly educated man has a great advantage over one who knows the technicalities of his work and little more; in lonely remote mining camps it is the idle hours that are the real menace to both body and soul. In this connection it is well to remember that on the last analysis it is the man, not his tools, that makes civilization, and the character of it will be either brutal or ethical according to the spirit he infuses into it.

There is another subject relating to an engineer's education that has received little or no attention, that is, his fitness and the indisputable importance of his taking an active part in the public life of the nation. We live today in a mechanical age, yet it is the rarest thing to find men who have had engineering educations in the supposedly deliberative bodies that make our laws or in the executive positions and offices that administer them. No country in the world affords such abundant opportunity for higher education as the United States and the least its recipients can do is to make some return in public service. During our Civil War the military officers on both sides of that unfortunate contest were largely recruited from the professions, chiefly the law; for in those days engineering had hardly reached the dignity of that designation. Yet today, although we are

living in an engineering age, the engineer as a citizen has no more influence or voice in public affairs than fifty years ago. This is all wrong, for it is a serious blunder that the laws now governing us should be framed and administered by men wholly unfamiliar with engineering in any of its branches. That men are competent to frame laws simply because they are lawyers is absurd, for law is or should be based on common-sense and a thorough understanding of the physical conditions affecting the different phases of human life and endeavor that it is intended to regulate. In the present War the British are drawing heavily upon the engineering professions for their army officers and the response has been gallant and unselfish. Now, conditions of life in England and the United States are almost precisely alike as to fundamentals and under similar circumstances we shall blunder, expend lives, treasure, and time just as they are doing, so the British are not only fighting our battles for us against the common enemy of liberty and all mankind, but they are giving us a vivid object-lesson as to how we shall err and behave when our turn comes. Anticipating that time, we are now engaged in a campaign of 'preparedness'; it is a most welcome sign of national sanity and it is to be fervently hoped it will continue unabated until something substantial is accomplished. The plan suggested by President Wilson in calling for the co-operation of our national engineering societies is a wise one, for they are likely to become the very backbone of any sane common-sense scheme of defense. And I think it will be found that the engineers who will become the most efficient leaders are those having broad educations and tolerant sympathies.

As to the over-crowding of the engineering professions in general and that of mining in particular, I would venture to say a few words. It is obvious, it seems to me, that if the engineer is to live a narrow life and confine himself strictly to the technical phases of his craft, the field is certain to be restricted and over-supplied. My notion is that simply because a man has had an engineering education and training is no reason why he should confine his activities exclusively to that class of work. The mere fact that a youth has had such an education ought to make him a better business man, a more efficient public servant, and a better all-around citizen than if he had not had it. It is a hard rough road to the top in any narrow strictly professional career, and one will notice if he looks carefully about him that today many, if not most, of our leading engineers are also good business men. It is certainly no disgrace to make a business of one's profession, indeed I would go further and say a man is a fool who neglects to do so unless he is on a salary and employed in strictly technical work having little or nothing to do with the commercial end of the organization with which he is connected. I think I have said enough to show that a professional man cannot be too broadly educated, but there is a great danger in sending out into the engineering professions men who are simply skilled artisans, whose hands are trained but not their heads; such men are useful for what they can

make in the same sense a brick-machine is valuable for the bricks it produces, but as its capabilities are strictly limited to that product, nothing more may be expected of it. A man, on the contrary is a living, growing, developing entity whose capabilities may often be unsuspected even by himself, until opportunity or force of circumstance compels him to do things he never anticipated doing. It is to the glory of our race that we so often do them well, and one may be thankful to live under a system of culture that develops the individual and in a country that affords abundant opportunity for personal initiative. We hear much said against soulless corporations, and indeed this indictment has often been justified, but it must be remembered that without the unity of individual effort in the form of corporations, there are a great many enterprises that could not be carried out; a corporation is simply a form of team-work in which a number of individuals are pursuing a common purpose in a co-ordinated effort. As our mineral resources become more and more depleted the individual has an increasingly difficult task in competing with corporations having great resources in both brains and money. As ores become leaner it is necessary to handle a larger and larger volume in order to make profit; a logical corollary to this is the increasing equipment and a pay-roll; hence the obvious and consistent line of least resistance is for the individuals to combine into an impersonal corporation. Of course, the tendencies of corporations is to stultify individual initiative, which is to be deplored, but it is hard to see how this may be avoided, although no doubt there are some corporations that give considerable latitude to their employees and due credit to their ability and genius. I believe a young man fresh from college should seek employment with a corporation whose system is well matured, and that has a sound traditional policy, even though the pay may be smaller than those organizations which appear to have no policy at all or treat their employees solely as parts of the machine designed for the purpose of making money. Men want money because they must live, but there is a subtle, though nevertheless distinct difference, between the attitude of mind which regards money solely as an end in itself, and that point of view which considers the wages of labor as the necessary complement to decent living. In other words, one cannot make a genuine success of life and disregard the human element in his daily work. Our system of culture was never intended to make machines of human beings, and we shall fight to the limit to resist anything of the kind.

COKE PRODUCTION of the United States in 1915 amounted to 41,581,150 tons, an increase of 20%. Of the total, 34% was by-product and 66% beehive-oven material, there being 5481 and 49,540 ovens worked, respectively. Pennsylvania made 25,622,862 tons of coke, followed by 3,071,811 tons in Alabama and 2,768,099 tons in Indiana.

TIN is being produced at Perth Amboy, in the A. S. & R. smelter, at the rate of 250 tons of electrolytic metal per month.

Specific Gravity Method for Tungsten Analysis

By J. J. Runner

It is probably true that in the great majority of tungsten ores, the gangue is composed dominantly of quartz. As a consequence, it would seem that the specific gravity of the gangue is a more or less constant factor. The ore-minerals of tungsten are, furthermore, usually confined to one of the wolframite series,* or to scheelite, the specific gravity of which is easy to determine. It is apparent, then, that if we know the specific gravity of the ore-mineral and of the gangue, we can easily calculate the percentage of the former from the specific gravity of the ore, and from this the percentage of WO_3 , or tungstic acid, in the ore, from the percentage of WO_3 in the ore-mineral, by means of the formula:

$$\text{Sp. gr. } O = \frac{x \times \text{sp. gr. } M}{100} + \left(\text{sp. gr. } G \times \frac{100-x}{100} \right)$$

$$\text{or } x = \frac{100 \times (\text{sp. gr. } O - \text{sp. gr. } G)}{\text{Sp. gr. } M - \text{sp. gr. } G}$$

where $\frac{x}{100} = \%$ by volume of mineral in ore

Sp. gr. O = specific gravity of the ore

Sp. gr. M = specific gravity of the pure ore-mineral

Sp. gr. G = specific gravity of the gangue

$x \times \frac{\text{Sp. gr. } M}{\text{Sp. gr. } O} = \%$ by weight of mineral in ore (W)

$W \times \% WO_3 \text{ in ore-mineral} = \% WO_3 \text{ in ore}$

For logarithmic calculation,

$\log WO_3 = \log (\text{sp. gr. } O - \text{sp. gr. } G) - \log \text{sp. gr. } O + [\log \text{sp. gr. } M + \log \% WO_3 \text{ in mineral} - \log (\text{sp. gr. } M - \text{sp. gr. } G)]$.

To test the efficiency of such a method I have determined, with considerable care, the specific gravity of 18 ores of tungsten that were at the time available in the laboratory of the South Dakota State School of Mines, and computed their WO_3 content, assuming the specific gravity of the gangue to be 2.65, of the wolframite to be 7.35, of scheelite to be 6.0, and the WO_3 content of wolframite 74.58%, and in scheelite 80%, and compared these results with the WO_3 content obtained by chemical analysis. The results were satisfactory as will appear from a study of the accompanying table.

The value 2.65 is taken as the specific gravity of the gangue, for in all of the underground samples used, it

was evident that the gangue was predominantly quartz, in some cases with small amounts of sulphides, oxides, and silicates, on the whole, resulting in specific gravities differing little, though slightly higher than that of quartz. For the specific gravity of the wolframite series, Dana gives 7.2-7.5, and here the mean 7.35 was used. For scheelite Dana gives 5.9-6.1, hence 6 was taken. In wolframite it was found that 74.58% gave the smallest differences between calculated and determined WO_3

CURVES SHOWING RATIO OF SPECIFIC GRAVITY OF TUNGSTEN MINERALS TO RICHNESS IN TUNGSTIC ACID.

content; hence this value was adopted. It was not thought permissible to obtain a value for WO_3 in scheelite in a similar way from so few data, so that 80% was adopted.

The material for testing, in the case of nine of the ores, was taken from laboratory specimens, and the entire mass was pulverized. In the other eight tests, samples were taken from materials already ground, so that there was no selecting of ideal samples. The ores represent 11 distinct districts, and the value of the method lies particularly in the fact that such close agreements can be obtained from random ores representing so many occurrences. In some cases, however, it is doubtful whether the specimen used represented the average ore of its district, for example, the specimen of Cornish ore

*Throughout this article the name wolframite is used for the hübnerite-wolframite-ferberite series. The differences between the members are of scientific rather than of practical value, since the percentage of WO_3 and the specific gravity of each is nearly the same. Speaking of the series between the end members, hübnerite, $MnWO_4$, and ferberite, $FeWO_4$, Hess says: "For the mixtures between these end members the older term wolframite may properly be retained and this term may well serve as a general or field name for the members of the series which cannot be definitely identified."

over the ore just to the boiling-point, so as to expel air-bubbles, then cooling to the room temperature, exhausting under an air-pump in order to remove any remaining air, filling the pyknometer with freshly boiled distilled water, and finally weighing at the room temperature. This method is recommended wherever possible. All other results were obtained by a method so simple that it can be done in the ordinary small-town drug-store or any place where a balance of fair accuracy is to be found. The only apparatus necessary is a thin rather long, slender-necked, Florence flask of 25 cc. capacity, with a scratch around the neck near the top, to serve as a mark. Such a flask may be obtained from any company dealing in chemists' or assayers' supplies, at a cost of only a few cents. If coarsely ground ore (size of a pin-head) is used, the sample may vary somewhat from the true average for the ore, but for ordinary purposes it is better for there will be less difficulty in getting the ore to settle, and less trouble with bubbles. However, finely powdered ore can be used with success, if one exercises sufficient care and can wait long enough for it to settle.

Place a weighed amount of ore, about 5 grams (or 75 grains) in the flask, fill about half-way with water, heat until it just comes to the boiling-point, cool in a basin of water, then in several changes of water at room temperature, and finally fill to the scratch with water that has recently been boiled and cooled to the room temperature, taking care that no bubbles or particles of ore are floating on the surface, and that the inside of the flask-neck is dry so that the water will not climb up the side above the scratch. Care at this point is vital, for inaccuracies here will lead to serious error in the final result. When the level of the water is nearly to the scratch, it is best to complete the operation by dropping in the remaining water from a glass tube drawn fine at one end, for a large drop in excess results in a considerable percentage of error. The flask should be filled until the central and lower part of the water surface is on a line with the level of the scratch on the near and far side of the neck. Weigh the flask, with its ore and water, when it has come to the room temperature. It is also necessary to obtain the weight of the flask filled to the scratch with water. This should be determined by using freshly boiled water at the room temperature, and taking the same precautions as for the flask, with ore and water, mentioned above. If the flask is perfectly dry when operations are begun, it is better to obtain the weight of the ore, by first weighing the flask empty, then with ore, and subtracting. The specific gravity of the ore can now be calculated from the formula:

$$\text{Specific gravity} = \frac{O}{O + fw - fow}$$

where O = weight of the ore

fw = weight of flask with water

fow = weight of flask with ore and water

Having the specific gravity, the approximate WO_2 content can be found from the accompanying curves. First find along the vertical column the number corre-

sponding to the specific gravity of the ore calculated from the formula, then follow the line nearest this value to the right until it crosses the upper curve, if a wolframite ore, or until it crosses the lower curve, if a scheelite ore, and from this point go straight down and read the percentage of WO_2 in the ore on the base-line. For example, it will be seen from the curve that a specific gravity of 4.7 corresponds to a WO_2 content of 51.2%.

Mineral Production of the Black Hills

The Mine Inspector's report for 1915, covering this part of South Dakota, gives the following output:

Mine	Tons	Value of gold
Golden Reward	58,827	\$484,995
Homestake	1,573,822	6,446,191
Mogul	37,419	161,605
New Reliance	27,645	61,508
Trojan	79,903	276,188
Wasp No. 2	111,290	183,488
Placers		1,822
Miscellaneous	950	3,887
Total		\$7,619,684

The Homestake also produced 25 tons of tungsten ore worth \$31,331, and the Wasp No. 2, 187 tons valued at \$147,730.

THE COBALT DISTRICT is beginning to show signs of prosperity since the price of silver rose. Exploration is increasing and search for the high-grade little veins is stimulated. Reginald E. Hore, a geologist who has given particular attention to northern Ontario, says editorially in the *Canadian Mining Journal*, "the geological structure at Cobalt is such that one can reasonably expect to find silver on some claims that show no ore at surface. It is characteristic of many of the orebodies in the conglomerate of the Cobalt series that they lie close to the underlying Keewatin and pitch with the sloping contact. Where erosion has worn the conglomerate thin, the ore outcrops. In other places, however, the ore does not extend to the surface, and can only be discovered by underground exploration." This helps to explain the disappointment that occasionally comes when a company removes the surface soil or unwaters a lake, hoping to find outcrops of rich veins. These may be present but not outcropping. The structure suggests the reason for lack of depth of many of the orebodies, because they are close to the contact of the underlying Keewatin, in which the veins are apt to be barren. Mr. Hore calls attention to the importance of studying the faulting system at Cobalt, and indicates also the significance of the thick sheets of diabase that intrude the other rocks. "On the theory that the lower contact of the diabase is a promising horizon, development at considerable depth is to be undertaken at the Beaver and Teniskaming mines, where the early workings were in rocks overlying the diabase."

Mining Around Lovelock, Nevada

By P. B. McDonald

Nevada has the least people and the most mines of any State in the country. It has more square miles than inhabitants, and for the most part is rightly pictured as an arid waste. There are, however, a few places where conditions favor ranching, and where oases appear in the sage-brush desert. These are the more attractive if they can be used for a headquarters by miners and engineers. Since the coming of the automobile, 30 or 40 miles can be traveled with ease, to give the dust-covered mining man a change of atmosphere at week-ends or between trips. Such an oasis is the town of Lovelock in the north-western part of the State on the main line of the Southern Pacific Railroad, the centre of a prosperous cattle industry and of varied mining activities. By aid of water from the Humboldt river, the valley produces excellent alfalfa for feeding cattle and sheep, which are sent from a wide area in the West to be fattened for the San Francisco market. Lovelock is preferred for this purpose rather than California, because it has no rainy winter.

A two-hours automobile journey south-eastward from Lovelock brings the traveler to the much advertised Rochester silver district, and the same distance northward are the Seven Troughs gold mines. The Humboldt range has long been a famous producer of the precious metals; it was here that the old Queen of Sheba and De Soto mines of George Hearst were situated. Regarding the foundation of the Hearst fortune, a writer in the *Oreland Monthly* remarked recently, "Little did the old-timers dream, as they prodded their oxen to brackish water-holes with creaking loads of ore, that the wealth they carried would some day appear in screaming headlines." A number of prospects and small mines are scattered throughout the region. Some are being operated, others are idle, and still others alternate between these conditions. Besides Rochester and Seven Troughs, I may mention Mazama, Vernon, and American Canyon, all small mining camps. At Rochester a half-dozen silver mines are operating, notably the Rochester Mines, Rochester Merger, Nevada-Packard, and Lincoln Hill; and at Seven Troughs are several gold mines, the more important being the Seven

Troughs Coalition, Seven Troughs Mining Co., and Mazama Hills. Tungsten has been found west of Lovelock; several mines are now producing tungsten ores, and one or two concentrating-mills are being operated near Toy, along the edge of the Humboldt sink. South-east of Lovelock, about 60 miles, is Bernice, near which are the antimony mines described recently by Willard Mallory.*

The two principal mines with headquarters at Lovelock are the Rochester Mines Co. and the Seven Troughs

WATER IN NEVADA. A SCENE AT LOVELOCK.

Coalition Mining Co. The former, a silver mine working on wide veins of moderately rich ore, is the largest producer in the Rochester district; it has extensive workings well developed by adits, and a 10-stamp continuous-decantation cyanide-mill of a capacity of 120 tons per day; the company recently accomplished the payment of an indebtedness of \$200,000. The Coalition mine, in the Seven Troughs district, is a spectacular producer of high-grade but pockety gold ore; its output last year was \$335,736, of which \$180,382 was paid in dividends. A 10-stamp mill extracts the gold by amalgamation, the concentrate being shipped to the Selby smelter on San Francisco bay. A cyanide-plant was destroyed by a cloud-burst several years ago, when 10 lives were lost. The mine is 1650 ft. deep, and the vein has been much faulted. In one month, October 1915, over \$60,000 was produced, at the rate of \$2000 per day from a 10-stamp mill—a pleasant performance while it lasted!

*M. & S. P., April 15, 1916.

The Rochester mine was operated under a leasing system up to a year ago. This did not prove satisfactory; it became apparent that the lessees were working the 300-ft. blocks as separate mines without any regard for the future. Drifts in the various blocks were not on the same level. Accordingly, the Rochester Mines Co. purchased the three leases for \$40,000; also the adjacent Weaver claims were secured. The lessees had produced \$938,515, all from ore averaging over \$20 per ton. The company, operating its own mine, has produced in nine months \$433,606, part of which was from purchase of custom ore. The machinery has been centralized at the mouth of the lower or Friedman adit. The upper or transportation adit has been straightened, widened, and laid with 12-lb. rails. There are three productive veins; the stopes vary up to 15 or 18 ft. wide, and the ore runs as high as \$90 per ton, but most of it averages \$10 to \$30 per ton. The ore is hand-picked before being sent to the mill. The cost per ton of mining during the nine months to May 15, 1916, was \$3.35, of which underground tramping absorbed 30c., timbering 35c., ore sorting 9c., and surface tramping 13c. Explosives cost 22c., and power 23c. per ton. For the month of May, 1916, the total cost of mining was \$3.10 per ton, showing a slight reduction. At present two shifts are worked; the night shift drills and breaks the ore, the day shift loads, trams, and sorts it. By this arrangement everything is made ready for the drill operators so that they have a minimum of interruption and bother. Also the requirement for power is distributed to equalize the demand; this is helped further by doing the coarse crushing at the mill when no power is needed for drilling. Power is furnished to the mine and mill by the Nevada Valleys Power Co., which derives it from the Lahontan dam, a government irrigation project 85 miles distant. The power is bought at \$8 per horse-power per month.

The mill was started to operate in March, 1915. A feature of the practice is the grinding of 93% of the ore to 200-mesh. The mill was designed by G. W. Wood of the Dorr Co. It is a continuous counter-current decantation cyanide-plant, using Dorr thickeners without a filter. A complete description of the mill, written by Mr. Wood,[†] was published in this paper a year ago. The cost per ton of treatment in the mill during the year ending May 15 last was \$2.69, of which coarse crushing and sampling took 16c., stamping 33c., tube-milling 60c., thickening 7c., agitation 52c., decantation 17c., and precipitation 49c. The cost for power was 56c. per ton. For the month of May 1916, the total cost of milling per ton was \$2.14, showing an appreciable reduction. Adding to this the cost of mining, \$3.10, the total is \$5.24. Indirect expense, such as transportation, water-line, taxes, etc., was 89c. per ton, making the total of all expenses \$6.13 per ton. This figure seems high but the practical difficulties overcome have been considerable.

The president of the Seven Troughs Coalition Mining Co. and the Rochester Mines Co., is L. A. Friedman of

Lovelock. Mr. Friedman has persisted in operating the Coalition mine since the rush to the Seven Troughs district, which came as an aftermath of the Goldfield boom

THE ROCHESTER MINE; ENTRANCE TO THE TRANSPORTATION ADIT.

in 1907. The Coalition mine has had a hard row to hoe, in spite of its high-grade ore. Faults in the vein, the disastrous cloudburst, and internal disagreements among stockholders have interfered with regular production. It has been necessary to go deep for the ore, and at times it has required considerable faith to keep going. Later, Mr. Friedman secured control of the Rochester Mines Co. His management has been criticized at various times. He has run things in a vigorous way to get results, and has conducted a wide publicity campaign for making the stock known on the mining exchanges. As indicative of the internal differences that have arisen, I may mention the recent statement by Mr. Friedman to the stockholders concerning the previous management. He said: "How men can do what has been done in the affairs of your company and escape the penalty of the law is beyond my comprehension." In a general way it should be remembered that any energetic man with a definite policy makes enemies; and to achieve results, he must be allowed to manage a mine according to his understanding of conditions.

[†]M. & S. P., August 28, 1915.

The Theory of Flotation

By H. Hardy Smith

IT appears to me that the problem of elucidating the theory of flotation could be greatly simplified by formulating some definite line of attack; the first consideration in which should be to segregate the various physical forces with their attendant phenomena, and to attack each in turn.

It is quite possible, in fact, most probable, that some of the forces come into play in all the phenomena, but by delivering a massed attack on each section in turn, perhaps success can be achieved more easily.

I suggest the following as a possible segregation:

(1) The physical forces governing the formation of bubbles in a pulp.

(2) The physical forces governing the attachment of bubbles to sulphide particles in a pulp.

(3) The physical forces governing the stability of the bubble attachment.

(4) The physical forces governing the stability of a bubble at the free surface of the pulp.

Leaving out of consideration those processes in which bubbles are formed in a pulp by the chemical action of one substance on another, and also Mr. Norris's unique process, in which minute bubbles are 'born' in a pulp which is super-saturated with a gas, and regarding only those processes in which a gas is introduced directly from an external source, segregation No. 1 will be found to present a considerable problem.

Several of your correspondents appear to be laboring under the delusion that it is simply necessary to introduce air violently into a pulp either by agitation or blowing, and immediately bubbles of the right number and kind obligingly form themselves. Anybody who has had practical experience with flotation, especially with the so called air-froth flotation, knows that most unfortunately this is not the case. No amount of agitation or blowing will produce bubbles of the right kind and number in absolutely pure water. A contaminating agent is necessary, and as some of the contaminating agents commonly used happen to be oils, concentration by frothing most unhappily has been named 'oil-flotation,' thereby masking the real significance of the use of the reagent. The action of certain substances in producing innumerable minute bubbles when air is introduced forcibly into a pulp, seems to be of fundamental importance, since without these bubbles the most common forms of froth flotation cannot be considered.

Professor Pollock of Sydney University, in Australia, has done some very interesting and useful work on this all important subject, and I believe has formulated a theory. I once saw a set of instantaneous consecutive photographs of bubbles, taken by him, showing their formation after the introduction of a blast of air. With

pure water the bubbles were mostly large, and even the small ones which were instantaneously produced had a tendency to collect together to form larger ones. With contaminated water the reverse was the case, the instantaneously produced large bubbles seeming to break down into smaller sizes.

From my experience in the practical application of the froth-flotation process, I am inclined to believe that many of the troubles that crop up from time to time at flotation plants are due to the inability of the reagent used to produce the required quantity of bubbles, owing to the appearance of some reactive substance in the pulp. Hence practical, as well as theoretical considerations demand a thorough understanding of the physical forces governing the production of bubbles in a pulp.

Coming now to segregation No. 2. More attention has been paid to this phase of the question perhaps than to any other, and rightly so, as it is of the utmost importance in all flotation processes, those employing the surface-film effect being excepted. Many writers pass lightly over the problem and simply state that the bubbles attach themselves preferentially to the oil or gas-filmed sulphide particles.

Let us now see whether this is possible if the two forces of surface tension and adhesion are alone considered. In the following discourse surface tension can be most simply defined as that force acting at the surface of all liquids which continually tends to reduce the surface area; and adhesion as that force which acts across the interface between two substances, which are in infinitely close contact, and tends to keep them from separating.

Consider a particle of sulphide mineral (which, for the sake of clearness, we may assume to be nearly spherical) and a bubble in close contact, in the interior of a pulp, but before the bubble has actually 'picked up' the mineral. (Fig 1). Even if the particle possesses appreciable adhesion for the water, the surface of the liquid in contact with the particle must be considered as tending to have surface tension, although the tendency is opposed by the adhesion. (See T. J. Hoover's 'Concentrating Ores by Flotation,' pages 50 to 55).

In the first case, assume the adhesion to be negligible. The surface tension forces that now come into play are shown in Fig. 1, where T_g is the gas-liquid, and T_s is the solid-liquid, surface tension. A glance at the force diagram will show that whatever the value and direction of the forces T_s and T_g , their component T_c can never be greater than $T_g + T_s$. Therefore surface-tension alone cannot rupture the intervening film, and cause the bubble to envelop the particle. If the particle possesses appreciable adhesion for the liquid, then the case is more hopeless still, as T_c must then be sufficiently

strong to rupture the intervening film and also to tear it away against the action of the adhesive force between the solid and the film.

Once a rupture has been effected, bubble attachment resolves itself into a struggle between surface tension and adhesion, the former strongly favoring a strategical retirement to the rear, from the salient, so as to straighten the line, and adhesion endeavoring to hold the right wing to its position.

As it is an established fact (See Fig. 2) (Mr. C. T.

In all probability this additional force manifests itself in the phenomenon known as the "hysteresis" of the contact-angle. Hysteresis is defined as the lagging of effect behind cause, and a contact-angle is the "effect" that is "caused" by bringing a solid surface in contact with a liquid surface in the presence of a gas. With many substances the "effect" (the contact-angle) does not assume its full value immediately, but lags behind. The reason why the angle changes can be fairly well explained if we assume that there is a force acting between a solid surface and a gas, tending to concentrate the gas on the solid surface; and that this force is strong enough to act across a thin film of the liquid.

In Fig. 3 the solid is a piece of glass, which is clean, and has been immersed for some time in the liquid.

Fig. 1.

Fig. 2

Bubble unattached
Bubble-Film continuous and
Bubble perfectly mobile.

Bubble attached and
Bubble-Film discontinuous

Durell notwithstanding) that a bubble contiguous to a surface with negligible adhesion does become attached almost immediately, so that its film forms part of a continuous film covering both solid and gas, there must be some force that causes rupture of the bubble-film at the point of contact.

In the case of two plain bubbles in pure water with their films in contact, the immediate coalescing can probably be explained by the difference in vapor-pressure existing in bubbles of different radii. But we add a contaminating agent for the very purpose of counteracting this force due to the difference in vapor-pressure so as to allow small bubbles to exist in the presence of larger ones; otherwise a froth would be an impossibility. Hence some force other than the difference in vapor-pressure must be present when one of the bubbles happens to have some, or all, of its interior space occupied by a sulphide particle.

Fig. 3.

Fig. 4

On drawing it through the surface, a contact-angle is immediately formed, and for any given angle, the forces T_{sg} , T_{lg} , and Ad are in equilibrium (ignoring gravity). If now the solid possesses the power to adsorb the gas through the very thin film at the toe of the angle, the adhesion of the liquid for the glass will be lessened and a corresponding surface-tension T_{sl} set up in the direction shown. This additional force will be sufficient to upset the state of equilibrium, the toe of the angle will recede, and the angle will increase in size. The stable angle will be reached when T_{sg} , T_{lg} , T_{sl} , and Ad have such magnitude and direction as to balance one another.

It has been found that those substances which possess the greatest power to vary the contact angle also show the strongest tendency to float under suitable conditions, and it is reasonable therefore to assume that this power has something to do with the attachment of bubbles.

The problem presented by segregation (3) is not

nearly so formidable as that just considered; it, as already stated, merely resolves itself into a struggle between surface-tension and adhesion. With most substances in their natural states, adhesion is altogether too strong, and, even if the film at the point of contact is ruptured, the bubble cannot attach itself on account of the inability of the surface-tension to tear the solid and the liquid surfaces apart. Hence either the surface-tension must be increased or the adhesion decreased. The latter course is usually adopted, as, with dilute solutions, the former is difficult; except for very small amounts is an impossibility.

Although an absolute increase in the surface-tension is out of the question, a relative increase is possible by raising the temperature. Both surface-tension and adhesion decrease with a rising temperature, but the latter much faster than the former; one being zero at the critical temperature and the other probably zero at the boiling-point. This is one of the reasons why solids that will not collect bubbles at ordinary temperatures, will do so when the boiling-point is approached.

The usual methods employed for decreasing the natural adhesiveness of liquids for solids are:

- (a) To allow the solid to take on a film of gas by adsorption (or occlusion?).
- (b) To allow the solid to take on a film of oil or other greasy matter by adhesion.
- (c) A combination of both (a) and (b).

While collecting evidence for one of the patent lawsuits that are ever with us, an interesting discovery was made. A piece of Broken Hill sulphide ore, taken from the centre of a large uncracked block, was found to contain 0.0037% of natural grease, as obtained by an ether extract. Samples were afterward taken from several other mines, and all gave an oily residue after extracting with ether in a most careful manner. Perhaps it is just as well to add that this was discovered accidentally and was not being specially sought as prospective evidence. This discovery goes a long way toward explaining the preferential adhesion of bubbles to sulphide particles.

The tenacity with which the bubble holds the particle depends on the length of the line of contact, which in turn depends on the size of the contact-angle, itself proportional to the relative values of surface-tension and adhesion. (See Fig. 1.)

If the adhesion is negligible, and the particle is large in comparison with the bubble, the result would be as shown in Fig. A.

If the particle is small, then the result would be as in Fig. B.

As adhesion increases, the tendency is for the particle

to get more and more out of the bubble and into the liquid until the surface-tension does not act over a sufficiently long line of contact to hold the weight of the particle, and it falls off.

The problem presented by segregation (4) has been dealt with in a most excellent manner by Mr. W. H. Coghill in your issue of February 26, 1916. His remarks in regard to a lowering of the surface-tension *per se* not being essential to the formation of a froth, are most timely.

The tension that exists in a pure liquid film is unlike all other tensions with which we are familiar, in that the stress is not proportional to the strain. Within the elastic limit (that is, the limit wherein the substance will return to its original shape when the contorting force is removed) a steel rod, or, taking what is more familiar still, a steel spiral spring, needs twice the pulling force to stretch it twice as much, and so on. The well-known spring-balance depends on this fact. But with a liquid film the same force can continue to cause an extension until rupture takes place, in spite of the fact that the film, right up to the point of rupture is within the elastic limit according to the above definition.

It is plain then that our common conception of a tension must be entirely revised when we come to deal with the tension at the surface of a liquid. For a system to be in a state of stable equilibrium it must offer a greater resistance to any force which tends to change its configuration, and as a pure liquid film does not fulfill this requirement it cannot possess stability.

The extreme instability of bubble-films is strikingly shown by the phenomenon in certain boiling liquids, with which we are all painfully familiar in our student days, called 'bumping.' In the absence of nuclei on which to form, the radius of a steam bubble when it first comes into being must be infinitely small, and the vapor-pressure to balance the surface tension of these small bubbles is large. Therefore before the bubbles can expand and rise through the liquid (that is, before boiling can occur) the temperature must be raised above the natural boiling-point of the liquid. As soon as the bubble has expanded to appreciable size, the vapor-pressure of the liquid is in excess of that necessary to balance the surface tension, and the bubble expands so rapidly that it literally explodes.

A boiler does not explode until its steel plates are actually ruptured, but the bubble explodes at the bottom of the beaker, that is, while its shell is actually in existence.

In the case of a solid, the greater the tension the greater the tensile stress developed; for a material of given strength, the greater the tensile stress, the greater the chance of rupture.

This line of reasoning does not hold in the case of a liquid film. The idea that a bubble film can be ruptured by the force of its own surface tension is about equivalent to the idea that a man can lift himself by his own shoe-strings.

It is obvious from the nature of the molecular forces

engaged, that the greater the surface tension the greater the ultimate tensile strength of the film. The lowering of the tension in itself therefore cannot give greater stability to a liquid film; but the surface adsorption, which accompanies the lowering of the tension in the case of certain solutes, can.

For reasons that need not be gone into, a solute which lowers the surface tension of a liquid, concentrates at the surface of the solution, but this process of concentration (called adsorption) takes a certain definite time to reach its full value. Now, if a film of the solution be stretched, new surface is produced, and this new surface at the moment of production possesses greater tension than the rest of the surface, because the surface adsorption has not had time to reach its full value. It therefore offers a greater resistance to the stretching force, and fulfills the conditions for stable equilibrium. So strong is the adsorption factor in certain cases, that practically the whole of the solute is concentrated in the surface layers, and therefore, although the absolute quantity in the solution may be exceedingly slight, the surface effect it produces is considerable. This explains the efficacy of the extremely small amount of contaminating agent used in some froth-flotation plants.

In a mineral-froth, it is strikingly obvious that those bubbles which have their films thickly studded with sulphide particles have their stability enormously increased. In some froths, one such bubble can be seen pursuing the even tenor of its way, amid a regular holocaust of its less fortunate brethren. The reason for this is not quite clear, but it is probably due to the adhesive force between the liquid and the solid.

The above remarks are given for what they may be worth, in the hope that they may be of some assistance to other mill-men, who, like myself, are anxious to see the inner workings of a flotation process clearly, as by the light of day, but at present, only perceive them dimly, as by the flicker of a candle at the far side of a 50-ft. stope. To the mind of the ordinary mining-man, much of the reading-matter available on the theory of flotation is just about as ponderous and obscure as a bull elephant cavorting in a fog. I sincerely hope that the preceding discourse will at least cause the fog to lift a little. Our heartfelt thanks are due to Mr. F. A. Fahrenwald* for giving those gentlemen their quietus who wished to solve the problem of flotation by leading us into the mystic realm of static electricity. I think the trio, surface tension, adhesion, and adsorption, if given an attentive and intelligent hearing, will acquit themselves admirably.

THE AMERICAN INTERNATIONAL CORPORATION, formed to promote participation of Americans in foreign enterprise, will confine its activities to a semi-banking business, encouraging the financing of railroads, steamship lines, light and heat services, water-works, etc. The Corporation will maintain representatives in foreign countries but permanent expenses will be kept low.

Explosives

Nitro-glycerine is a limpid oil formed by the action of a mixture of nitric and sulphuric acid upon ordinary glycerine. This chemical action is a violent one unless carefully controlled. After it has taken place, the nitro-glycerine is washed repeatedly to remove any trace of acid that might remain. The presence of acid is dangerous in the finished explosive because it may produce a chemical action of disastrous results. For practical use, the liquid nitro-glycerine is so sensitive to percussion and friction that it is dangerous to transport it or attempt to employ it alone. However, when nitro-glycerine was first introduced for driving the Hoosac tunnel in Massachusetts, and for springing oil-wells in Pennsylvania, it was used alone, being carried in copper cans and loaded in tin tubes. In the oil-well region, men made an occupation of driving a horse and light wagon through the country for carrying the pure nitro-glycerine to the consumers. Many accidents were reported, and a carrier's position was scarcely to be envied.

Later it was learned to mix the nitro-glycerine with a quantity of kieselguhr, an infusorial earth composed of the silicious skeletons of minute diatoms, and therefore called diatomaceous earth. The nitro-glycerine is absorbed by the earth, which is itself inert and simply forms a plastic mass that can be more safely handled than the nitro-glycerine. Another advance came when it was found that nitro-cellulose, or gun-cotton, could be dissolved in the nitro-glycerine to form a nearly uniform jelly. This mixture constitutes blasting gelatine. The gun-cotton is made by the action upon cotton fibres of the same acids as are used in the manufacture of nitro-glycerine, great care being taken to wash away all trace of excess acid. When gun-cotton, or nitro-cellulose, is incorporated with the nitro-glycerine, it shares in the explosion, instead of acting as an inert base like kieselguhr. Thus additional power is gained. Blasting gelatine, then, is a mixture of two complex compounds, which fact increases the possibility of chemical change with consequent deterioration and danger. Blasting gelatine contains 92% nitro-glycerine and 8% nitro-cellulose. There are, also, various intermediate mixtures of nitro-glycerine and nitro-cellulose with a proportion of wood meal and potassium nitrate, the object being to produce effects intermediate between straight dynamite and blasting gelatine. When such a complex mixture was attempted, it was at first difficult for any mechanical method to render a perfectly homogeneous mass, but later methods of manufacture have improved this.

The initial pressure of the different explosives when detonated in their own volume are as follows: straight dynamite (nitro-glycerine mixed with an inert base) 80 tons per square inch, blasting gelatine 113 tons, gun-cotton 71 tons, black powder 21 tons. It is evident that blasting gelatine is the most powerful. Likewise it has the highest rate of detonation, 25,262 ft. per second, as against 22,368 for straight dynamite and 984 for black powder.

*The Electro-statics of Flotation, M. & S. P., Feb. 26, 1916

Platinum on the Pacific Coast

By T. W. Gruettler

SOUTHWESTERN Oregon and northern California are the chief sources of platinum in the United States. In this region it is recovered as a by-product from gold placers. At the present time the greater part of the platinum is won in the Californian alluvial flats where many dredges are at work, and where more attention is given to saving the fine metal than at the average hydraulic mine.

David T. Day says in 'Black Sands of the Pacific Slope,' a U. S. Geological Survey bulletin, on page 3: "If only two-thirds of the platinum in the heavy sands going to waste at hydraulic mines in California and Oregon were saved, the total production would exceed the present consumption of the United States."

The platinum in the sea-beaches from Gold Bluff, California, to Coos Bay, Oregon, varies from 1:20 to 1:5 as compared with gold, while in the dredging areas on the Feather and Yuba rivers it is from 1:1000 to 1:3000. Eight large samples of natural sand from Crescent City southward to the vicinity of Gold Bluff, averaged 48c. gold and platinum per ton. Eleven similar samples from Crescent City north to Coos Bay averaged 61c. gold and platinum. The largest proportion of platinum to gold, along the coast, is in the vicinity of Pt. Orford. Where the rivers cut large bodies of serpentine (dunite), the usual source of platinum, the metallic particles are coarser than on the beaches. Along the rivers they are often encased in hematite, chromite, olivine, serpentine from olivine, etc. From 20 to 50c. per yard is not uncommon.

Iridosmine, one of the platinum group carrying a high percentage of iridium, forms a higher proportion of the platinum along this part of the Coast than in any other locality in the world, one Oregon sample being 37.30%.

J. E. Kemp, U. S. Geol. Surv. Bull. No. 193, p. 19. The iridosmine is generally a mechanical inclusion in the platinum and is present as fine brilliant plates. Aqua regia will dissolve the platinum from the nuggets, which then fall apart and leave the fine plates exposed.

As usually found, the platinum will pass a 20 mesh screen. It cannot be separated from the heavy black sand by means of riffles. The flakes of platinum and gold drift over the surface of the black sand and will not concentrate easily. At mines where all the heavy sand is saved, it is sometimes panned by hand or shipped to a smelter. As platinum will not amalgamate, gold can be separated from it with ease. When the miner ships the black sand to a smelter, the platinum is not paid for. Some mines, by table or centrifugal concentration, will keep a rich product for shipment, discarding the tailing, which is a wasteful method. Digs and hydraulic classifiers are also used, particularly on dredges, to improve a

low-grade concentrate, the coarse concentrate being ground fine to release the precious metals. This refers to inland placers where the sand is coarse.

Occasionally low-grade black sand is treated with quicksilver to get at the gold, and then sodium is added to make sodium-amalgam and the platinum extracted with this. However, the sodium soon decomposes and often lets go of the platinum before it is collected. Electrolytic sodium-amalgam is also used and is the only practical success known to me. Panning is a tedious and expensive process. When machine concentration is used, it is generally carried too far, a concentrate being made that is worth, say, \$3000 to \$20,000 per ton. Of course, this usually gives only a few pounds of concentrate, the greater part of the valuable contents being lost in the tailing, which are discarded.

Within recent years dredging and hydraulic mining companies have given more attention to close saving but except where electrolytic sodium-amalgam is used, there is still a large loss of platinum and coated gold, as well as gold amalgam from 'flouring' and 'sickening.' There are immense areas of rich sand where the gold and platinum are flaky and coated. These can be worked with electrolytic sodium-amalgam at a handsome profit, as described already.* The treatment is preceded by a two-stage concentration process, the concentrate being made no richer than can be done without excessive loss in the tailing. A 95 to 100% recovery is not unusual. The cost ranges from a fraction of a cent to several cents per yard, to which concentration is added. Concentration on a 2400-yd. basis would be about 2c. per yard or less. Mining costs run from 1c. to 10c. per yard in ordinary cases. In this system there is no loss from oxidation of sodium, coatings of silica, oil, slime, oxides, etc., unless the metallic particles are wholly encased. With the present high prices for the platinum metals it would pay many mines to add electrolytic amalgamation to their equipment. First costs vary from \$500 to \$3000 in addition to concentration machinery. The new system has been much improved and a high degree of efficiency and simplicity has been attained. The correct design of the apparatus is a somewhat complicated matter, but once installed, anyone can run it. I have not patented my improvements and would be pleased to give further details on application.

As already stated, platinum is mostly derived from serpentine. Prospectors should test deposits of chromite in serpentine. A simple and reliable test is as follows: Have your druggist order 1-oz. stannous (tin) chloride crystals; 1 package 4-in. white filter-paper; buy from

*M. & S. P. November 6, 1915.

him a bottle two-thirds filled with strong hydrochloric acid, another with nitric acid; a third for dissolving the stannous chloride (bottles should be about 1 or 2 oz. each with glass stoppers); two droppers and several 5c. test-tubes complete the outfit, which should not cost over \$1 nor weigh over 1 pound.

In a test-tube put a small pinch of finely-powdered ore or sand; drop on this four drops hydrochloric acid with one dropper and two drops nitric acid with the other dropper, taking care not to draw the acid into the rubber bulb, and washing. Warm contents of tube gently with a match held on the side, keeping mouth of tube pointed away from your face. This will dissolve most of the gold in a few minutes. If not testing for gold, this solution may be poured away. Add fresh acid in the same way and pour off all but enough to well cover the sand. Boil with several matches. Then pour what is left of this solution over a piece of filter-paper. From the stannous chloride bottle pour a little over the filter-paper. Where the two solutions meet on the paper a bright orange color will appear if platinum is present. The gold solution crossed with the stannous chloride gives a red-purple or brown-purple color, according to concentration. If both metals are present, both colors will appear and the intensity of color is in proportion to concentration and richness. The tin crystals are dissolved with water and hydrochloric acid, about half and half. Leave the bottle open occasionally, as this produces stannic chloride and improves the action.

FOREIGN TRADE is becoming important to mining and manufacturing companies in this country. Since the War has called attention to it, interest has arisen as to how such business is transacted. How our exports of copper are marketed in Europe, how tin is bought in London and shipped direct from the Straits Settlements, how mining machinery can be sold in South America or Russia, all these questions have exercised the minds of those engaged in American industries. The trade at American ports, particularly New York, has increased greatly, and efforts are being made to retain permanently the new ties of foreign business. The National City Bank of New York points out, in a recent publication, how London has built up its commercial supremacy. Two principal reasons are given. First, because the port was free to all the world with few restrictions or encumbrances. Secondly, because shippers in remote countries had confidence that a cargo of anything, sent to London and consigned merely to the general market, would receive fair and expert treatment in storing, grading, and sale to buyers that would speculate in any product. A shipper could draw immediately on a consignee and receive part payment.

THE MINING LAW of this country contains a stipulation that discovery of a valuable mineral must be made prior to locating a claim. Regarding this, Horace A. Winchell, the well-known authority on mining law, has remarked "In other country, so far as I am aware, re-

quires a prospector to make an actual discovery of mineral in place before staking out his claim. The more you think of it, the more absurd it becomes. A prospector is a man searching for mineral. He must necessarily be protected in his possession while he is searching for his vein, but under the present law he is a trespasser upon the public domain until he has found his vein. Twenty-five years ago it was perhaps an easy matter to make a discovery without any prospecting work. Today it is exceedingly difficult." This was said in discussion of a paper by Courtenay De Kalb in a bulletin of the American Institute of Mining Engineers.

Zinc is temporarily more important than copper in the Central or Middle-Western States, says a press bulletin of the U. S. Geological Survey. The zinc production of the Mississippi valley was worth \$17,139,264 in 1914 while the copper output of the Central States, mostly from Michigan, was \$21,865,043. But for 1915, the value of the zinc produced reached the remarkable figure of \$53,540,472, or over three times that of the previous year. The copper production increased to \$46,494,969 and more than doubled in value. The value of the copper produced in the Central States had for years exceeded that of zinc, owing to the higher price per pound received for the copper, while the quantity of zinc produced has been larger. In 1915, the output of copper in the region mentioned was 101,300,000 lb., greater than in 1914, but the low figure for 1914 was partly due to a disastrous strike of copper-miners in Michigan. The 1915 output of zinc exceeded the 1914 production by only 95,700,000 lb., but the proportionate increment in price of the zinc was greater than for copper. "The salient facts relating to zinc and lead mining in the Central States in 1915 were the building of new mills and roasting-plants in the Wisconsin-Illinois region; the increased output and the better recovery made by flotation in the disseminated-lead district in Missouri; the more general use of thickeners, classifiers, and tables and the vastly larger yield from the sheet-ground in south-western Missouri; the development of the new mining territory near Picher and Cardin, in the north Miami field in Oklahoma; and the active prospecting and mill-building and the increase in shipments of zinc carbonate in Arkansas." It is interesting to note that two of the principal uses of spelter in the manufacture of war munitions are for galvanizing the barbed wire used in making wire entanglements and in making the brass for cartridge-cases and parts of projectiles. The average price paid for spelter in the United States during 1915 was 14.44c, which is nearly three times the 1914 average of 5.36c. Zinc has truly been the "metal sensation of the War." It is generally predicted that the reaction in the price of zinc will be more decided than in other industries, but as no one expected anything different, the event will be sufficiently discounted. Some authorities predict that after the War, zinc will drop to its former price of 5c., but others expect a price of about 7 cents.

CONCENTRATES

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

EIGHTEEN ELEMENTS have melting-points above 1700 C.

ELECTRIC HAULAGE in the Hollinger mine, Ontario, resulted in a saving of 7c. per ton in tramming charges last year.

ANACONDA, a copper producer, yielded 8,064,986 oz. of silver last year; Nipissing, a silver producer, yielded 4,097,301 oz., or about one-half of the former.

FLOTATION at the Broken Hill Proprietary Co.'s works in Australia has produced 744,816 tons of zinc concentrate from 2,988,919 tons of tailing, since 1904.

ROCK-DRILLS working in the Homestake mine, South Dakota, number 575. There is 4500 lb. of dynamite used daily. On two 8-hour shifts 1200 men are underground, extracting 4500 tons of ore.

AN ASSAY-FURNACE burning crude-oil at the Rosario mine, Honduras, effects a saving of P500 to P600 per month over a charcoal type, and also allows the work to be done in two-thirds of the time.

WOOD-FLOUR and wheat-flour refuse, worth about \$15 per ton, are used in the manufacture of dynamite to absorb nitro-glycerine. Flour of a good white color is preferred, as dynamite is judged for freshness by its light color.

WOUNDS should not be treated with mercuric chloride dressings, if iodine has been applied. The consequence would be the formation of mercuric iodide, which is strongly irritating. To remove mercuric iodide, wash the wound with a 10% solution of potassium iodide.

CHROMITE, or iron chromate, usually called chrome-iron ore, is used in chemical manufacture to make salts used in tanning, also for a refractory lining employed in basic open-hearth steel furnaces, more particularly where the silica brick arch meets the magnesite lining of the hearth. Most of the present supply to this country comes from New Caledonia and Rhodesia. The high ocean-freight has given a market to the California product, obtained chiefly in Shasta, Tehama, Tulare, and Fresno counties. The chemical trade demands a 15-55% ore, for refractory brick a 35-40% ore will suffice.

TO ALLOW TAILINGS to flow where they may without obstruction, is to risk the loss of any valuable metal retained. If they lodge on the lands of another, they are considered as an accretion and belong to him. If they accumulate on vacant and unappropriated public land, it has been the custom of the mining regions of the West

to recognize the right of the first comer to appropriate them by proceedings analogous to the location of placer claims. The Supreme Court of Nevada ruled that, although not a mining claim within the strict meaning of the expression as generally used in this country, a "tailing claim" is so closely analogous to it that the propriety of subjecting the acquisition and maintenance of the possession of it to the rules governing the acquisition of the right to a strictly mining claim at once suggests itself. The Land Department has recognized this possessory right and permitted entries to be made on lands containing beds of tailings, under the law applicable to placers. There are no adjudicated cases in the reports of department decisions upon this subject that have come under our observation, but we have knowledge of several instances where patents for this class of claims have been issued under the mining laws.

WOODEN BLOCKS, creosoted, which are already used extensively as paving material for city streets, are coming into use as flooring for warehouses, factories, shops, platforms, etc. Floors made of wooden blocks placed on end are noiseless under heavy traffic, durable, sanitary, and easy on the feet of workmen. The high cost is a disadvantage, being \$2.40 per square yard for the completed floor. The wood commonly employed is Southern yellow pine, although hemlock, larch, Douglas fir, black gum, beech, and maple are also used. The blocks are sawed from long sticks of timber and are treated in steel cylinders of 6 to 7 ft. diam. and 100 ft. long. Creosote-oil is run into the cylinders, and pressure is applied to force it into the wood. The oil is a product obtained from the manufacture of coke from coal. Wood saturated with creosote does not decay, shrink, or swell to the extent customary with untreated wood. The blocks are laid usually on a concrete foundation, with the grain of the wood vertical so that the most resistant surface is exposed. The joints and cracks are filled with hot pitch or asphalt.

DUST LOSSES in smelting plants should be investigated, and a systematic study usually proves worth while. Although the advantages of this work are fairly obvious, the limitations should not be overlooked. Estimates of dust losses by any methods at present in use are subject to considerable errors. The average of a number of tests is a close approximation to the truth. One set of tests gives a figure that applies to the particular operating conditions of that time only, and no estimates can safely be made from it of dust loss under different operating conditions. In using the results of these tests, a probable error of 10% is allowed at the Copper Queen smelter at Douglas, according to J. M. Samuel in a paper prepared for the A. I. M. E. Changes will probably improve methods from time to time; but in measuring the dust content of a flow of gas in a conduit, variations in flow and composition of gas, under ordinary operating conditions, are so great that the average of a number of tests rather than individual tests will always have to be depended on for accuracy.

Electric Hoists on the Rand

*Exclusive of winches there are 143 electric hoists at the Rand mines, their combined continuous rating being over 74,000 hp. Power is obtained from local steam plants, the largest of which are those of the Victoria Falls Power Co., which have a total capacity of 220,000 kw. (This concern originally intended to generate power at

VIEW OF COMPLETE HOIST.

the Victoria falls on the Zambesi river, nearly 700 miles distant from Johannesburg, but the difficulties of transmitting high-voltage current over such a distance were so great that steam plants were decided upon near the mines.)

Near the centre of the region is the property of the Crown Mines, which in 1915 produced 763,061 oz. of gold from 2,497,000 tons of ore. Reserves are estimated

Number of turns of rope on cone.	25
Maximum speed, revolutions per minute.	53.5
WR of revolving parts of hoist (less motors), pound-feet	15,816,000
Time for acceleration, seconds	12
Time for retardation (assumed), seconds.	10
Rest period, seconds	7
Weight of skip, pounds	8,700
Weight of ore per trip, pounds.	16,000
Size of rope, inches diameter.	2
Weight of rope per side, pounds.	22,300

As will be seen by the photograph, direct-connected to the drums at each end is a 22-pole, 2000-hp., 53.5-r.p.m., 550-volt, shunt-wound motor. The remainder of the electric apparatus includes a 4-unit, motor-generator set consisting of one 16-pole, 5000-hp., 375-r.p.m., 2000-volt induction motor; two 14-pole, 1650-kw, 375-r.p.m., 550-volt shunt-wound generators; and one 60-kw, compound wound exciter together with the necessary control apparatus. The hoist motors and generators operate in series.

The accompanying chart shows operation of the hoist when lifting from the 3540-ft. level. It was found that when winding from the deeper levels the apparatus did not heat as much as when hauling from the upper levels. While hoisting from the higher parts of the shaft the rope never leaves the cylindrical portion of the drums; on the other hand, while lifting from deeper levels the conical effect of the drums is used.

Tin is least important of the metals from a military standpoint. It is used in war munitions only for a minor part in British shrapnel, and some other metal could undoubtedly be substituted. The recent high price cannot be laid to war consumption, but rather to the uncertainty of supply because of high ocean freights.

Tin, which is now selling around 41c. per pound, sold for an average of 42c. during 1913, for 37c. during 1914, and for 39c. during 1915. The *Daily Metal Reporter* of New York remarks that "it is indeed fortunate that tin is not an absolute requisite in the manufacture of munitions of war, for it is a relatively scarce metal compared with iron, copper, lead, and zinc." The import of tin into the United States during 1915—and this country is the greatest consumer—was 57,000 tons or about 1000 tons per week; this figure is only a fraction of our output of copper or zinc. The new smelter of the American Smelting & Refining Co. at Perth Amboy, New Jersey, is now smelting Bolivian concentrate. The process includes roasting in a Wedge furnace and smelting in a 12 by 38-ft. reverberatory provided with oil burners. Refining is done electrolytically—a new departure in tin making. The output averages 99.97% fine, which is better than the famous Straits tin, and the capacity is 15 to 20 tons per day, approximately 10% of the consumption in this country.

DUTY-CYCLE WHEN HOISTING FROM 3540 FEET.

at 9,938,000 tons of \$6.25 ore. Over a year ago a General Electric hoist of the following construction was installed at the South Rand shaft of the company, the shaft being 3540 ft., inclined at an angle of 90° to the horizontal, according to notes by F. L. Stone:

Type of drum.....double cylindro-conical
Diameter of rope centres at small end of drums, feet 12
Diameter of rope centres at cylindrical end of drums, feet 20.75

TALC production in 1915 was 166,336 tons worth \$1,041,197.

*Abstract from *General Electric Review*, June, 1916.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

SUTTER CREEK, CALIFORNIA

PIMMING AT THE EUREKA.—LINCOLN AND OTHER MINES TO BE RE-OPENED.—CENTRAL EUREKA AND KENNEDY.

Two of the three sinking pumps have been installed in the old Eureka shaft and are discharging a large stream of water. The compressor and other parts of the plant are working well. So far operations have been done only on one shift, but the shaft crew has been increased and on June 20 work began on three 8-hour shifts. As the water is lowered, the shaft-timbers are found to be in an excellent state of preservation, notwithstanding the fact that the last work done at the mine was during 1886; in fact, it is said that much of the sets will not have to be renewed, now that the cave at the collar of the shaft has been caught up. Miss Marguerite Beam formally opened the mine by blowing the whistle last week, on the day the pumps

RE-OPENING THE OLD EUREKA AT SUTTER CREEK.

were finally coupled up and put into operation; it was a sound most welcome to Sutter Creek residents.

The sale of the well-known Lincoln group of mines to men interested in the old Eureka property was confirmed late last week, the purchase price being given as \$295,000. The sale includes the Lincoln mine proper, as well as the Wildman, Mahoney, and Emerson claims. With the exception of some prospecting at the Lincoln a few years ago, no work has been done on this stretch of mining ground for over 10 years, financial difficulties having caused the closing down of the mines and their subsequent loss by the last operators. The assistant United States treasurer, W. J. McGee, and other local men are largely interested in the present deal, as they, incorporated under the name of the Lincoln Consolidated Mining Co., came into possession of the combined properties after the old company's failure to raise the funds necessary to pay off mortgages and equip the property for development. The mines have been opened by four shafts: the Wildman, 1400 ft. on 72° incline; Emerson, 619 ft. vertical; Mahoney, 1200 ft. on 62° incline; and Lincoln, 2000 ft. on 63° incline. The intention of the former management was to sink the Emerson vertical shaft down to the point necessary to cut the large vein found in the Wildman property on the 1400-ft. level. This shaft was

sunk in diabase 1000 ft. east of the Wildman, and the expectation was to cut this great orebody at a vertical depth of 2300 ft. This vein at 1400 ft. in the Wildman was opened for 160 ft., solid quartz assaying over \$3 per ton, and should be made to yield a good profit with proper working facilities. Two 40-stamp mills are on the property, but owing to their old style and dilapidated condition, they, with most of the other equipment, will have to be replaced with modern machinery. The Wildman and Mahoney plants were formerly driven by water-power, the company owning a large reservoir and pipeline for this supply. The purchasers are said to be Michigan men of whom T. Hoatson is one of the principals. T. Walter Beam, president and manager of the Eureka, has taken formal charge of the Lincoln property, and such tools and supplies as will not be immediately needed at the Lincoln are being transferred to the Eureka. The Wildman claim adjoins the Eureka ground and underlies the town of Sutter Creek.

At the Central Eureka 70 men are employed, where 20 stamps of the 40-stamp mill are in steady operation on ore from the 2800, 3000, and 3100-ft. levels. Some development is contemplated at 700 ft., and preparations are in progress for sinking a winze below the 3200-ft. level in accordance with suggestions made by C. E. Juhlén, who examined the property recently for the purpose of outlining the mine's future development. Fred Jost of San Francisco is superintendent.

At the Kennedy mine at Jackson, preparations are nearly completed for sinking the shaft to a depth of 3900 ft. This vertical shaft is now said to be the deepest of any gold mine in the United States, and the ore developed on the lowest levels is quite as rich as that worked in the levels above, insuring the stockholders handsome quarterly dividends.

WASHINGTON, D. C.

MINING ON INDIAN RESERVATIONS.—MINING LAW.

A bill, prophetic of what may take place some day, is that of Senator Ashurst of Arizona before the Senate to authorize mining for metalliferous minerals on Indian reservations in Arizona. It directs the Secretary of the Interior, under regulations to be fixed by him and under such terms and conditions as he may prescribe, to lease to citizens of the United States or to any associations of such persons or corporations, any part of the unallotted lands within any Indian reservation in Arizona, withdrawn from entry under the mining laws, for the purpose of mining for deposits of gold, silver, copper, or other minerals, the leases to be irrevocable except under such breaches provided against in the bill. Ninety days after enactment of the bill the lands are to be open at all times for exploration for minerals, the claims to be located in the same manner as mining claims are located elsewhere under the mining laws of the United States. It is provided that the locators or their heirs or assigns shall only have a preference right to apply to the Secretary of the Interior for a lease within one year after the date of location, and that any locator who shall fail to apply for such a lease shall forfeit all right to his mining claim.

The leases are to be for a period of 50 years, with the preferential right to renew them for successive periods of 10 years under conditions and terms to be prescribed by the Secretary of the Interior. Relinquishment is also provided for, should the locator desire to give up his claim. On application by him

he may also acquire during the term of the lease a tract of unoccupied land, not exceeding 20 acres in area, for campsites, milling, and smelting works, and for other purposes connected with the proper development and use of the deposits covered in the lease. For the United States the right is reserved to dispose of the surface of the land embraced within the lease, in so far as the land may not be necessary for use of the lessee in extracting and removing the deposits of the land. Leases may be canceled and forfeited by the Government by appropriate proceedings in the United States district court. For the privileges of mining the lands the lessee is to pay to the United States a royalty of 2% of the gross value of the output of the minerals, payable at the end of each month succeeding the extraction of the mineral from the mine, and an annual rental, payable at the date of the lease, of 25c. per acre for the first calendar year, 50c. for the second, third, fourth, and fifth year, and \$1 for each succeeding year during the continuance of the lease. In addition it is provided that the lessee shall expend annually not less than \$100 in development work for each mining claim located and leased. The Secretary of the Interior is given full power to examine the books and accounts of all lessees and to require them to make statements, all under oath. The money from all royalties and rentals is to be deposited in the Treasury of the United States to the credit of the tribes of Indians having tribal rights in the reservations in which the leased land is located. The rights of all States and local authority is conserved, such as collection of taxes. Senator Ashurst has also introduced a bill in the Senate authorizing the Secretary of the Interior to lease for the production of oil and gas ceded lands of the Shoshone and Wind River Indian reservations in the State of Wyoming, the moneys resulting to go to the Indians, and the regulations to be fixed by the Secretary of the Interior.

Nothing has as yet been done by the committee on mines and mining of the House of Representatives on the bills providing for the codification of the mining laws of the country. The committee seems to have gone asleep over the matter, in spite of its enthusiasm manifested early in the winter. Those in charge, however, appear quite impressed with the many caustic letters that have been received in criticism of the so-called Foster bill codifying the mining laws. It seems almost assured that no codification bill will become law in this Congress.

TORONTO, ONTARIO

PORCUPINE, KIRKLAND LAKE, AND COBALT.—STEEL.

At Porcupine the Dome management has definitely decided to substitute ball-mills for stamps, and has ordered three more machines of the 8 ft. by 20-in. type already found highly satisfactory.

Construction on the 2000-ton per day addition to the Hollinger mill has been started the contracts having been let for the concrete foundation.

Diamond-drilling at the West Dome is showing excellent results. Four veins have been cut, the last at a depth of 700 ft. below the surface, being 10 ft. wide and heavily mineralized. The shaft is down 227 ft. on a vein, carrying free gold, and will be sunk to the 300-ft. level.

The McIntyre has cut a 16-ft. vein on the 1000-ft. level. This may be an extension of that previously found at the same depth of the McIntyre Extension.

Frank L. Culver, president of the Timiskaming and Beaver companies of Cobalt, has acquired a large interest in the Schumacher, and has been elected a director of the company.

At the Vipond the shaft has been connected by a raise from the 400 to the 300-ft. level, making the high-grade ore on the lower level accessible for hoisting to the mill.

Developments at the Porcupine Premier, formerly the Standard mine, 100-ft. level have been encouraging. A number of Boston people inspected the property on June 3.

At Kirkland Lake good progress is being made with the development of the Labelle Kirkland. This embraces 265 acres, across which run several dikes believed to contain rich ore. The shaft is down 330 ft. on a high-grade vein which has persisted all the way, and will be followed to a greater depth. A station has been cut at the 270-ft. level.

The Lake Shore has opened ore containing free gold and tellurides on the 300-ft. level, and the vein is thought to extend into the Teck Hughes property.

The mill of the Tough-Oakes is treating about 120 tons of \$20 ore per day. The company is laying out a townsite to the north of the mine.

Large shipments of ore were made from Cobalt last week, the total amount from 10 companies being 454 tons. Total bullion shipments for the year to date were 3,225,545 oz.

The Trethewey mill is again in operation, treating broken ore that was formerly left in the mine because of the low price of silver when the mine closed down.

The Kerr Lake has taken an option on the Maidens property in South Lorrain, where it is thought that there is a considerable body of low-grade ore.

The annual report of the Peterson Lake for the year ended April 30 shows a total income of \$393,183. After paying dividends, \$277,376 was carried forward. This was practically all derived from royalties paid by the Seneca Superior.

The Ophir and the Peoples mine have effected an agreement for the joint development of their properties down to the contact of the Keewatin and diabase at a depth of approximately 600 ft. The surface of both mines shows a number of strong veins with low silver content.

Steel plants in the Dominion are very busy, mainly on war and export orders. One result of this unusual activity is a shortage in the output of steel rails, which is greatly retarding railway construction in the West. The annual report of the Dominion Steel Corporation of Sydney, Nova Scotia, for the year ending March 31, shows the largest profits in its life. The net manufacturing earnings were \$7,004,316, an increase of \$3,433,258 over the previous year. After all deductions for interest, depreciation, and dividends the net surplus remaining was \$3,015,225. One-half of the total output of the year was exported.

Two Cobalt, Ontario, silver producers in 1915:

	La Rose Mines	McKinley- Darragh- Savage Mines
Development, feet	4,393	4,538
Ore reserves for mill, tons.....	10,000
Ore reserves, ounces	1,871,280
Ore milled, tons	54,165	63,661
Average content, ounces	15.28	17.165
Recovery, per cent	76.7	80.9
Ore and concentrate shipped, tons..	17,105	18,938
Silver content, ounces	1,071,694	1,197,815
Net value received	\$481,663	\$515,101
Cost per ounce, cents.....	31.64	28.71
Net profit	\$230,662	\$231,433
Balance brought forward.....	\$1,032,811
Dividends paid	\$228,000	\$269,723
Balance carried forward	\$886,850	\$280,299
Silver shipped to date, ounces.....	22,891,968	15,183,661

The general manager of the La Rose, R. B. Watson, reports that only a small amount of high-grade ore remains in pillars, but in clearing-up the mine other small shoots will be found. Some dumps should yield a small profit.

At the McKinley-Darragh-Savage, T. R. Finnane is manager. Ore reserves in the McKinley were maintained, but as the property has been thoroughly prospected the chance of finding other important orebodies is slight. Before the Savage mine's possibilities are exhausted a considerable amount of exploration remains to be done.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

ANCHORAGE

Contrary to general belief, the Federal government has withdrawn from lease only a small area of the Matanuska and Bering river coalfields. There has been surveyed over 200 sections of 640 acres each, and under the law the Department of the Interior is authorized to withdraw 19 of these sections, but it has not done so, according to the *Anchorage Daily Times*.

The mine inspector, Sumner S. Smith, who has been in conference with Franklin K. Lane in reference to the leasing regulations, is of the opinion that the entire field, with the exception of Government reservations, will be open to lease. Applicants can go on the ground and designate any area they desire to lease, subject, of course, to the usual mode of procedure. Regulations governing the leases are based upon the idea of the immediate development of the coalfields on an extensive scale, and to prevent speculators from getting hold of the land. Those who are willing to spend the most money on the development of a mine will be given the preference in the granting of leases. Mr. Smith believes that the coal can now be mined on a workable basis, and an important resource of Alaska fully developed.

Reports from Anchorage state that a large number of men are going to the new placer strike at Tolstoi in the Innoko district, many centres in the Kuskokwim valley losing their population. Dogs have risen in price 200%. As usual, opinions differ as to the prospects of the ground. A town-site has been laid-out at the mouth of Boob creek. The distance by water from Iditarod to Cooper, the new town, is several hundred miles, but the diggings can be reached by dog-team traveling cross-country in a 60-mile journey.

JUNEAU

Satisfactory progress is reported in construction of the treatment plant of the Alaska-Juneau company. At the coarse-crushing plant concrete work has been completed, and steel is now being erected. Good progress has also been made with concrete work on the mill and power-plants.

ARIZONA

COCHISE COUNTY

Water from the precipitating plant at the Lowell mine of the Copper Queen is to be pumped into stopes containing low-grade sulphide ore to dissolve the copper. This will be returned to the surface for precipitation on iron as usual, and returned to the mine continuously.

GLA COUNTY

It is reported in Boston that the Old Dominion company is to spend \$1,000,000 on additions to its mill, power-plant, and smelter, also for residences. This will be spread over some time.

At the Inspiration mill some of the sections are treating over 1000 tons per day each; their rated capacity is 800 tons. Improvements to the Macey mills have helped to do this. The last of the Colorado and Joe Bush ore-dumps have been cleaned up and sent to the mill. Underground work is evident by the large craters forming on the surface near the shafts. Drainage of the ore-body is well ahead of sto, in.

GREENLEE COUNTY

Although the Arizona Copper Co.'s employees have signed an agreement with their employers, as did also those at the other mines in the Clifton-Morenci district, yet last week some men at the Coronado mine, Humboldt mine, and No. 6

KING INCLINE OF THE ARIZONA COPPER CO. AT METCALF.

concentrator called a strike without authority. A Mexican mucker at the Coronado, considering that he had done enough work for the shift, downed tools before the regular time; others followed his example. After some argument with the superintendent, this resulted in the mine being closed. The grievance committee investigated the trouble, two men were discharged, and the mine resumed. At the Humboldt a man was discharged for some reason, whereupon the next shift refused to work unless he was re-instated. The grievance committee's efforts were fruitless, and the mine, with the concentrator, was shut-down. Eventually the difficulty was settled, and operations re-started.

MARICOPA COUNTY

A plant to treat gold, silver, copper, lead, and zinc ores by amalgamation, concentration, flotation, and cyanidation, is to be erected at an early date at Wickenburg.

MOHAVE COUNTY

(Special Correspondence.)—Activity at Oatman is largely confined to the southern end, particularly to that part known as the Pioneer vein system. This formation extends into the Oatman Pioneer from the Arizona Tom Reed. Work at the latter is still largely prospective, but some good results have been obtained. The main shaft is down 100 ft., and a 5-ft. vein assaying around \$10 has been cut. Greater depth will be obtained, as on the same vein in the Pioneer good ore was not obtained until depth was reached. On the 200 and 400-ft. levels in the Pioneer ore is being followed toward the Arizona Tom Reed ground with good results.

Another active property is the Paramount, joining the Pioneer on the south-east. At present the principal work of the company is confined to the erection of surface plant at the main shaft, which is sunk directly on the vein. Excavating is under way at the mill-site and for the hoist. A contract has been let for a 60-hp. electric hoist, and it is expected that the transformer will be running in 60 days. Two shifts are working in the mine. The shaft is down 70 ft., and is to be sunk to 300 ft. The drift at this point will be watched with interest, as it will settle several theories regarding the formation of the vein system in the southern end of the district. In the Paramount the drift will be driven toward a junction of several well defined and proved veins, one coming from the Arizona Tom Reed and the Pioneer, and others from a more southerly direction. The question is whether high-grade ore will be found at this junction.

The vein system of the southern end of the district is peculiar and interesting. It comes from the east in the Lexington Arizona as one large lode, which branches out in that property to big veins, one of which passes into the Boundary Cone and the other into the Paramount, both of which properties join the Lexington on the west. The more southerly vein again branches out in the Paramount, one of which goes into the Pioneer and the Arizona Tom Reed and others in a more southerly direction. As yet but little prospect work has been done on these junctions.

Oatman, June 19.

The Elkhart gold-silver-lead mine in the Chloride district has been acquired by the A. S. & R. Co. The property has a past production of \$1,300,000, and has been idle for 12 years. The workings are flooded, and unwatering is under way. The Tennessee zinc mine adjoining is owned by the U. S. S. R. & M. Company.

YAVAPAI COUNTY

In the Shamrock mine of the New State group of claims, 8 miles south of Prescott, 6 ft. of \$19, 14 in. of \$276 ore, and a dike of \$7 gold ore has been opened. This is one of the best developments for some time. A number of promising mines are near-by.

In an interview with the *Jerome News*, W. A. Clark of the United Verde company said: "We will increase the output of our plant here as soon as the all-steel fireproof smelter at Clarkdale is placed in full operation. The smelter is the latest word in the construction of a metallurgical plant. More houses will be built at Clarkdale. Additional school facilities will also have to be built, but I never regret money spent for schools. Butte, my home city, has more schools and better equipment than any town of its size that I know. In Jerome, arrangements will have to be made to take care of the additional force that will be employed when the smelter is in position to operate at capacity. The Verde district certainly has encouraging prospects. A few good mines will result from the numerous corporations that are forming here this year."

YUMA COUNTY

It is probable that the Swansea smelter will be re-started for custom ore. The plant has been examined by A. C. Cole.

ARKANSAS

MARION COUNTY

The north Arkansas field yielded 5,000,000 lb. of ore during May. Seventeen of the forty mines produced zinc carbonate, which was shipped direct. At Rush the Yellow Rose mine has a 100-ton mill at work.

CALIFORNIA

BUTTE COUNTY

The Bear Canyon manganese mine at Clipper Mills has been closed on account of a dispute between the owner, G. Woolley, and the Noble Electric Steel Co., which is operating it for its smelter at Heroult, Shasta county. The ore is high grade. Woolley is opening a good deposit of chrome-iron near-by.

CALAVERAS COUNTY

(Special Correspondence.)—The McKnight Mining Co., operating the Hamby mine, is making many surface improvements. A 650-cu. ft. Sullivan compressor and motors have been installed. A 20-stamp mill, with concentrators and amalgamator, are almost completely erected and housed in a corrugated-iron building. Electricians are nearly through with the wiring and the plant will soon be ready for work. The hoist for the present will be driven by steam generated with fuel-oil. It is contemplated in the near future to use a motor, using steam as auxiliary power. Luther Everitt is superintendent.

The Mokelumne Mines Co., a subsidiary company of the International Investment Syndicate of Los Angeles is now operating the Easy Bird mine at this place, together with adjacent property, covering an area of 400 acres. A 457-cu. ft. Ingersoll-Rand compressor, driven by electric power, has been installed. A 75-ton plant with amalgamators, concentrators, and classifiers will be installed soon, and a cyanide plant for treating concentrate on the ground, may be erected. A contract has been let to John Casey and Herbert Blais for the construction of a road from the mine to the public highway, whereby freight to and from the mine may be hauled to Martel station by auto-trucks. For the present ore will be milled from the upper workings, above the adit-level, where a good body of \$8.50 ore has been blocked out. Work will soon be commenced on a three-compartment shaft, by raising from the adit-level about 350 ft. to the surface and by sinking from the same point. An electric hoist will soon be installed. A. M. Howat is superintendent and H. J. Wendler is manager.

Work, Sharpe, and Reade are re-opening the Xmer adit in Stockton hill. This is a 2000-ft. tunnel into the Ancient Channel mine, and it is expected that the gravel will be reached about July 1. The property is equipped with a Boise gravel mill, which has a capacity of about 90 tons per 24 hours. Water from the Mokelumne Hill canal will supply power and for washing the gravel. H. E. Sharpe is in charge of the underground work, and F. B. Work will attend to surface operations.

Mokelumne Hill, June 19.

KERN COUNTY

The Baltic mine and mill and the Buckboard claims near Randsburg have been sold to Los Angeles people headed by A. O. Hunsaker, J. C. Woodmancy, and L. H. Harrod for \$100,000. The mill is to be remodeled.

NEVADA COUNTY

At Ormonde, above Washington, 160 acres of patented ground has been acquired by the Columbia Consolidated Mines Co., of which E. C. Klinker is manager. The company's

area is now 430 acres. The Ocean Star and German mines were also bonded by the company.

Amalgam was stolen from the plates at the Black Bear mill near Rough and Ready last week. Quicksilver was also taken.

Lumber and machinery amounting to \$70,000 has been ordered by C. A. Brockington of the Grass Valley Consolidated Gold Mines, to be used in re-opening the Allison Ranch mine. R. L. Hathaway, of Nevada City, will erect the buildings. The Taylor Foundry & Engineering Co. will supply some machinery, Wellman-Seaver-Morgan Co. the electric hoist, American Deep Well Co. the electric pumps, and Sullivan Machinery Co. the compressor, etc.

SAN BENITO COUNTY

A plant of 250-ton daily capacity, consisting of a ball-mill and tables, has commenced treating quicksilver ore at New Idria. Most of the ore comes from the company's San Carlos mine, which is of considerable promise, is at a much greater elevation than the plant, and is being connected with it by an aerial tram about $1\frac{1}{2}$ miles long. The cinnabar in the San Carlos occurs differently to that in the Idria, where narrow veins are the rule. Three furnaces are also at work treating over 300 tons daily.

SHASTA COUNTY

Zinc ore amounting to three carloads daily is leaving Kennett for smelters in Kansas. A car of blister copper is sent East every day.

The Mammoth Copper Co. is to erect an electrolytic plant to treat the zinc fume caught in the furnace flues. Wages will be lower in June on account of the drop in price of copper during May.

SIEIRA COUNTY

For the sum of \$5200, part of the North Fork-Wisconsin property near Forest has been purchased by the North Fork Mining Co. Both companies had claims on one another and settled disputes amicably. The Wisconsin is to open its gravel-claim from a certain point, while the North Fork opens its vein through an incline. D. E. Hayden and G. F. Stone are the respective managers.

SOLANO COUNTY

A farmer, W. Hawthth, and others have erected a large drilling outfit just north of Vallejo. A hole will be put down to 1700 ft. to test the ground for oil. The prospecting will cost \$30,000.

TRINITY COUNTY

From its property near Wild Wood the Manganese Company of California is to extract 10,000 tons of chrome ore this summer. This will be carried on auto-trucks, over a road to be improved to Redding.

YUBA COUNTY

Near Parks Bar on the Yuba river the Yukon Gold Co. has 50 men constructing its new dredge.

COLORADO

CLARK CREEK COUNTRY

(Special Correspondence.) Flotation at the Argo mill, Idaho Springs, Colorado, is giving remarkable results. Custom ore containing copper, lead, gold, and silver yields 9% of its metal-content. A good recovery is made on carbonates. Free gold is also said to be floated. The medium is 85% of Wyoming fuel-oil and 15% of pine-oil.

Idaho Springs, June 18.

At Georgetown the Capital mill is working regularly.

GLENNSON COUNTY

At Vulcan the Vulcan Mines & Smelter Co. has blown-in a new furnace. Sulfide copper ore from the Vulcan-Good Hope mine is to be reduced. C. H. Mace is in charge.

LAKE COUNTY (LEADVILLE)

At a point 1700 ft. from the portal of the Valley adit in Prospect mountain, and at a depth of 150 ft. below it, iron-silver-manganese ore has been cut by the interior shaft. A 50-ton lot was sent to the Arkansas Valley smelter at Leadville. This development is of great importance to the district.

At the Wolfstone shaft the water is down 100 ft. below the 800-ft. level, leaving 80 ft. to be drained.

The Penrose shaft of the Down Town property has been unwatered to the bottom, namely, 874 ft. Work commenced on May 8, 1915. A Providence Manufacturing Co. centrifugal pump of 3000-gal. capacity, against a 900-ft. head, is being installed. It is to be driven by a 650-hp. G. E. motor. The present flow is 1700 gal. per minute.

OURAY COUNTY

The Benack Mining Co. is to drive a new adit, 500 ft. below the present outlet.

SUMMIT COUNTY

A car of ore, 27 tons, in three lots, assaying 10.5, 97.5, and 1470 oz. gold per ton, also some silver, worth a total of \$30,000, was shipped last week from the Dunkin mine near Breckenridge to the Globe smelter at Denver. The sampling company devoted 10 days to sampling the lot. Gayman, Knorr, Whar-ton, and Summers are the lessees.

TELLER COUNTY (CRIPPLE CREEK)

The well-known Cresson mine has been sold to Colorado and New York capital for \$1,270,000. A. E. Carlton negotiated the deal. The Colorado men in the purchasing syndicate are Charles M. MacNeill, Spencer Penrose, Eugene P. Shove, John C. Mitchell, Harry James, and Louis Noble.

IDAHO

SHOSHONE COUNTY (COEUR D'ALENE)

The Marsh Mining Co., which has been operating near Burke until two weeks ago is to be reorganized as the Consolidated Marsh Mines Co., capitalized for 2,000,000 shares at \$1 each, against the 1,500,000 shares in the old company. The new corporation will take over all the holdings of the company, the Green Mountain Mining Co., of which the Marsh has control, and probably some adjoining properties, the extent of which has not been decided on.

An 18-in. shoot of galena has been opened on the 1100-ft. level of the Hypotheek mine near Kingston. The new 125-ton mill is doing good work.

MICHIGAN

THE COPPER COUNTRY

(Special Correspondence.)—The committee of Lake Superior shareholders of the Centennial company, formed last year to attempt to bring about a plan for consolidation with the Osceola Consolidated, has dropped operations for the present. They have information to the effect that G. M. Hyams of Boston is a shareholder in Centennial, although not owning the stock so that it shows on the books. Under the circumstances they think that if they made their proposal to the Osceola—both corporations being under Calumet & Hecla management—Mr. Hyams would be almost sure to bring some sort of court action that would prevent consummation of the deal, no matter how fair the shareholders of the Centennial or those of the Osceola might look at the proposal. Their assumption in that direction is due to the court action which Mr. Hyams took against the Tamarack's consolidation, when that plan and price of purchase of Tamarack stock by the Calumet & Hecla was considered fair by practically every Tamarack stockholder.

Houghton, June 19.

In the Tamarack and C. & H. business the latter will only grant until July 1 its time-limit for completing the purchase.

Mr. Hyams would not waive an appeal from the decree of the Court now hearing the case.

MISSOURI

The ore market last week showed little change. The output of the Missouri-Kansas-Oklahoma district was 7639 tons of blende, 64 tons of calamine, and 979 tons of lead, averaging \$68, \$49, and \$80 per ton, respectively. The total value was \$666,456.

Losses caused by the heavy rain (6 in. from 10:30 p.m. to 4 a.m.) on June 19 amount to \$500,000, half of which was at the mines. Three men were drowned in the Coral mine, near Chitwood. The Grace mill, of 200 ton capacity, also near Chitwood, was struck by lightning and destroyed by subsequent fire. There were 3500 telephones put out of commission.

MONTANA

BROADWATER COUNTY

Developments at Copper City are reported to be encouraging. The Three Forks company has a shaft down 400 ft., cutting good veins. Good equipment has been erected. Power is available from the Montana Power Company.

SILVERBOW COUNTY

At the Butte & Superior, according to the general manager, J. L. Bruce, development of the 1700 and 1800-ft. levels shows larger and higher-grade orebodies than the 1600-ft., though on that level the ore-shoot is 1600 ft. long. During the last five years the mine has produced more than 1,250,000 tons of ore from the levels above 1600 ft., and above that depth there is more ore than was blocked-out when the company took hold of the property. Ore reserves are so large that the mine can go on producing zinc at its present rate of 180,000,000 lb. annually indefinitely. The lower price of spelter has reduced the value of concentrate; in January the product was worth \$101.60 per ton, in May \$65.25. The May output was 11,658 tons of concentrate from 50,688 tons of ore. The mill is being re-modeled to increase the capacity by 50%. Ball-mills are to be installed in place of some rolls. Foundations are being prepared for the new hoist and primary crushing plant.

The Davis-Daly is producing 100 tons of 2.5 to 6% copper ore daily, the better grade coming from 2500 ft. depth.

Development at depth in the North Butte is said to have been disappointing of late.

The Bullwhacker mine is sending 100 tons of 4% copper ore to the Pittsmond, or East Butte smelter, daily. Regular shipments also go to Tacoma and Garfield. Development is satisfactory, and costs are low.

Re-organization of the Butte & Bacorn is proceeding satisfactorily, nearly \$264,000 being available for resumption of work.

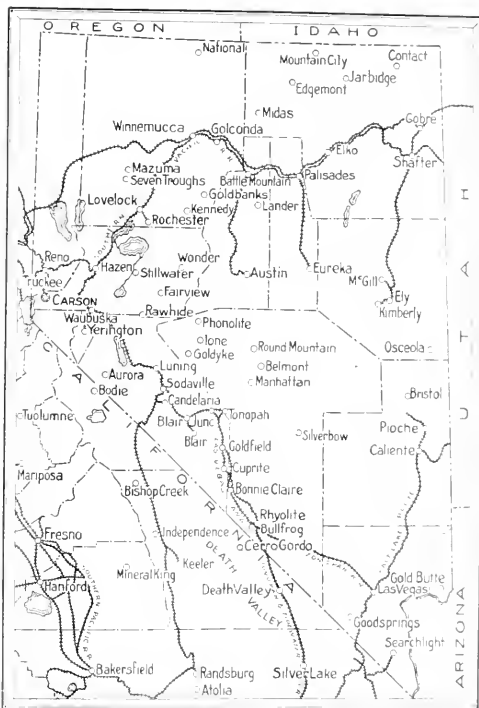

NEVADA

According to Victor C. Heikes of the U. S. Geological Survey, who recently visited Nevada, there is optimism for the future of the zinc-mining industry, though disappointment regarding the present price of spelter, among operators in the Yellow Pine district and at Goodsprings, who are sending out a large quantity of ore. There is considerable activity, also, in the Battle Mountain district.

All of the ore-loading platforms are covered with ore from the different properties, and five dry mills are in operation. These use crushers, screens, and the Stebbins dry concentrating table, and are making a concentrate that runs about 60% lead. In the Goodsprings district they are using caterpillar trucks for hauling ore, each truck carrying 30 tons of ore per trip. These and the narrow-gauge railroad are kept busy. The Yellow Pine Mining Co. is producing a heavy tonnage. The placer fields in the Battle Mountain district are being vigorously worked and extended. All of the larger properties, including the Glasgow & Western Exploration Co., in which

Salt Lake mining men are heavily interested, are prosecuting a vigorous campaign of development work. The Glasgow & Western company is in a process of liquidation, and Joseph Ralph, who is handling that end, expects to dispose of the property to Salt Lake interests. F. Sommer Schmidt, of Salt Lake, is in charge as general manager. The company is a British concern, in which the Coats family, thread manufacturers, are interested. The 100-ton flotation mill was started last week on the Battle Mountain Mining & Development Co.'s property in Lewis canyon. On the Greenah property, near Lodie, a station on the Nevada Central railroad, running between Austin and Battle Mountain, a remarkable vein has been opened by the Lemaire brothers. The high-grade ore carries native gold and silver chlorides. The Winnemucca Mining & Milling Co.'s 100-ton cyanide mill is about ready to begin operations. Construction has been delayed somewhat on account of the failure of the transformers to arrive according to schedule.

"Everything is prospering in the country tributary to our line," according to Frank M. Jenifer, traffic manager of the Tonopah & Tidewater railroad in the *Tonopah Bonanza*. "The

mines of the lower country around Death Valley are rapidly developing a tonnage that is all the more surprising since this is the dull period of the year. South of Beatty, I estimate there are 450 men steadily employed, and there is a good chance for the number to increase as more work is being done and more improvements installed by every company operating. The Tecopa company has just finished its concentrator that treats 75 tons daily, and, in addition to this, the company is delivering to us an average of 35 cars a month. This company owns 11 miles of standard-gauge railroad connecting it with several mines with the T. & T. tracks at Tecopa. At Grant, 12 miles east of Tecopa, I understand the company has opened one of the richest orebodies in its holdings. The Gunsight and Noonday mines are keeping up their output. At Death

Valley Junction the roaster of the borax company is running to capacity. At Baker, 40 miles north of Ludlow, one of the Riggs properties is shipping three cars a week of silver-lead ore. The manganese mine at Owls' Head that has attracted so much attention was sold recently by Alexander Yeoman to the Mollett Development Co., a steel concern of Massillon, Ohio, for \$50,000. This company is shipping at the rate of 1000 tons a month. It has put in two 30-ton Holt caterpillar tractors to haul the ore the distance of 27 miles to the railroad at Riggs. The Ithex at Zabriskie has been taken over by the Goodsprings company, and is preparing for an output of zinc ore that will almost equal the production of the parent mine at Goodsprings. This company is putting on auto-trucks, and may build a narrow-gauge line to cover the distance of 14 miles between the tracks and the mine. The company at Carbonate has had trouble in finding the right type of tractor, but now has secured one that is capable of doing excellent service. This motor came in recently, giving the company two trucks and tractors capable of delivering 500 tons per month."

CLARK COUNTY

The old Umberseat mine, known as the Carbonate King, is employing 25 men and producing zinc ore, in charge of F. A. Crampton of the White Pine Mining Co. The occurrence of zinc ore here adds considerably to the Goodsprings belt. Lead is also contained in the ore.

The Quartette gold mine at Searchlight has been sold to the Dupont Copper Co. of New York for \$120,000.

ESMERALDA COUNTY (GOLDFIELD)

Exploration in new ground is under way at 1750 ft. depth in the Atlanta. Other work on this and the 1580-ft. level has revealed considerable low-grade gold-copper ore.

Better ventilation has been secured at the Merger through its recent connection with the Jumbo Extension.

Development has been resumed at the Lone Star Consolidated in charge of Emory Arnold. Work was started at 225 ft. depth. The Silver King mine at Hornsilver has been acquired by A. H. Elftman and Eastern people.

LINCOLN COUNTY

At Freiberg, 65 miles west of Pioche, the Alamo Mining Co. has opened gold-silver-copper-lead ore in a limestone-diorite-porphry contact. This is a new and promising area.

WASHOE COUNTY

Last week the Union mine on the Comstock produced ore worth \$15,000. This included 112 tons of \$71.05 and 155 tons of \$31.81 ore from the 2100-ft. level, and 50 tons of \$18.43 ore from 2500 ft.—The Mexican mill treated 389 tons averaging \$39.20 per ton.—The Sierra Nevada continued repair work at 2400 and 2500 ft.—The Ophir and Con. Virginia advanced drifts at 2700 feet.

OREGON

JOSEPHINE COUNTY

Grants Pass people are trying to re-start the Takilma smelter, which has been closed since 1908. About \$4000 is required to overhaul the plant, which is of 100-ton capacity. Ample ore is available.

SOUTH DAKOTA

LAWRENCE COUNTY

Gold ore is again being extracted at the Wasp No. 2. On account of water from recent rain, mining was suspended for several weeks. Dividends since January 1 total \$100,000, mostly derived from wolframite production.

The value of the gold, silver, and lead produced in South Dakota in 1915 from 33 productive mines, 10 of which were placer, amounted to \$7,597,752, compared with \$7,131,313 in 1914, as reported by Charles W. Henderson, of the U. S. Geological Survey.

UTAH

BONLEDER COUNTY

At the Lakeview zinc-lead mine on Promontory point there are 90 men employed. The May output was 800 tons netting \$16,000. Dividends, including \$5000 on May 12, total \$100,000 since October last. The lead ore averages 26%, and zinc ore 32% metal.

JACOB COUNTY

(Special Correspondence).—Under the direction of Forbes Rickard, H. M. Byllesby & Co. of Chicago has opened a large tungsten deposit near Lovelock, Nevada. Five hundred tons of scheelite has already been shipped to the plant of the Utah Minerals Concentrating Co., at Eureka, Utah. Operation of this mill has proved quite satisfactory to the management. Already several hundred tons of tungsten ore from different producers in Nevada and northern Utah have been treated. The management attributes the success of this plant to the elimination of stamps in favor of rolls. The extraction has been from 70 to 82%, which is expected to be increased. As it stands now the plant is probably doing as good work as could be expected, considering the class of ore received for treatment.

Ogden, June 18.

MILLARD COUNTY

Sawtooth is the name of a new gold-copper district, 45 miles south-west of Oasis on the Salt Lake Route, 30 miles north of the Beaver County line, and 50 miles east of the Utah-Nevada State line. The altitude is 8000 to 9000 ft. There is plenty of water and timber nearby. The veins are mostly found on contacts.

SALT LAKE COUNTY

An extensive deposit of molybdenite has been developed at the Alta Glandstone mine in the Little Cottonwood district. About 400 sacks are ready for milling. F. Redmond and L. S. Besley are lessees.

In Big Cottonwood canyon the American Consolidated Copper Co. has cut 30 in. of copper ore at a point 1200 ft. in from the portal of the adit.

SUMMIT COUNTY

Further trouble is brewing for the Silver King Consolidated at Park City, whereby Solon Spiro, one of the directors, and the company are sued by J. C. Dugan for the return to the company of 72,180½ shares and \$87,205.20, plus 20,000 shares and \$20,000, alleged to have been wrongfully obtained and appropriated by Spiro. The plaintiff owns 9000 shares in the company. The details are somewhat complex.

CANADA

BRITISH COLUMBIA

Ore sent to the Trail smelter is increasing in volume. In the week ended June 19 the total was 10,826 tons. For 23 weeks the total is 224,472 tons.

A large quantity of zinc carbonate ore is being opened in the Hudson Bay mine near Salmou. Shipments of 60 tons daily average around 30% metal. The cross-cut adit to open the vein at a depth of 1750 ft. is in 600 feet.

During April the Standard Silver-Lead company at Silverton received \$95,115 from 729 tons of lead ore and concentrate, also \$26,847 from zinc sales. The profit was \$86,773. The surplus is \$320,926, after distributing \$50,000.

On June 30 the Hedley Gold Mining Co. pays a quarterly dividend of 3%, plus 2% extra.

ONTARIO

The Beaver Consolidated shaft is down 1630 ft. Cross-cutting is to be done at 1600 ft. to explore above and below the contact. At 530 ft. a 4-in. shoot of rich ore has been opened for 20 ft. A flotation plant may be added to the mill. In

May there was 186,433 oz. of silver in storage, and 108,050 oz. in ore. Cash amounted to \$92,484. On April 29 a dividend absorbed \$60,000. During the quarter ended May 31 the company did 1868 ft. of development.

YUKON

The Silver King mine in the Mayo district has been sold by T. Aitken to Manley, Ives, Price, and McGinn, well known in the North. When the mine is in order and roads passable, a daily output of 15 to 20 tons is expected. During the winter Aitken mined 1700 tons worth up to \$200 per ton. This deal is considered one of the most important in years.

KOREA

The Seoul Mining Co. reports the following results for May:

Bullion	\$49,140
Concentrate	55,660
Total recovery	\$144,800
Expenses	55,000
Operating profit	\$89,800

Copper is calculated at 18c. per lb. The recovery of this metal was 92.6%.

The Oriental Consolidated company's May yield was worth \$132,000.

MEXICO

SONORA

Practically all Americans have left Cananea. Their departure was made quietly and secretly, the Mexicans being in the dark as to movements made. General Calles issued a note

THE UNITED STATES-MEXICO BORDER DISTRICTS.

to the Mexican population ordering them to respect the Americans and their property.

Americans from El Tigre are also in Arizona. Loyal Mexicans will continue to operate the mine and mill until compelled to suspend work. Bullion was brought across the border safely last week, also concentrate from Nacoziari.

Many hundreds of Mexicans are passing through Agua Prieta on their way south.

The LAKE SUPERIOR MINING INSTITUTE will not hold its usual August meeting, but will meet January 20, 1917, when the iron mines are not so busy, for making a trip to Birmingham, Alabama.

PERSONAL

Note: The Editor invites members of the profession to send pictures of their work and appointments. This attention is a direct invitation to others.

MYSON L. S. WESSEL has returned to Smuggler, Colorado. HORACE V. WINCHELL passed through San Francisco on June 24.

ROBERT HAWKHURST sailed from New York for Nicaragua on June 23.

O. G. ENGELDER has returned for a visit in the United States from Sardinia.

STEPHEN BIRCH was married on June 24 to Miss Mary Rand of Minneapolis.

RAYMOND SPERR is with the Keweenaw county road commission, Michigan.

W. H. STAYER has opened an office in the Krise building, Lynchburg, Virginia.

R. B. BURNSMADE has returned from Mexico and is at St. Louis, 4429 Morgan street.

HUGH ROSE, resident manager of the Santa Gertrudis, is at Williamstown, Massachusetts.

J. D. SPERR has resigned as mining engineer to the Tom Reed Gold Mines Co., Oatman.

P. S. HARRY, mill superintendent of the Seoul Mining Co. of Korea, is at the St. Francis hotel.

E. FLEMING L'ENGLE has been appointed manager of the Royal Zinc Co. at Joplin, Missouri.

R. S. PRATT, superintendent of the Iola zinc mine in Kansas, recently visited at Houghton, Michigan.

A. J. CLARK, who is operating tungsten mines at Bishop, California, was in San Francisco this week.

HARRISON A. DENX, a graduate of the Michigan College of Mines, is reported to be in prison in Mexico City.

P. J. JANSEN, manager of the Simau mine, Sumatra, Dutch East Indies, is here on a metallurgical journey of observation.

FRANK A. LOVE has been appointed superintendent of the Elkhart mine, at Chloride, Arizona, recently acquired by the A. S. & R. Company.

F. W. SPERR is attending the annual meeting of the Society for the Promotion of Engineering Education held at the University of Virginia.

W. E. THORNE has entered into a new contract for two years more with the Lenskoie Company of Siberia, for selecting dredging and hydraulic ground and sampling same.

THEO. C. DENIS has been released from service in the French army at the request of the Canadian government, and will reserve his position as Superintendent of Mines in Quebec.

ALBERT DICKSON, of San Francisco, secretary to the Washington Mines Development Co., of Douglas, Arizona, was shot and probably fatally wounded June 21 in an ambush fight with a band of Mexicans near Chuppas, State of Sonora, Mexico.

H. KENYON BURKH, chief engineer of the Inspiration Consolidated Copper Co., has completed his work pertaining to the design and construction of the plant, and will leave on July 1 for an extended vacation trip throughout the East. His forwarding address for the next few months will be care the Sierra Madre Club, L. A. Investment building, Los Angeles.

THE EDITOR will be grateful for occasional good photographs of subjects relating to mining and metallurgical operations. They should be printed on glossy paper.

THE METAL MARKET

METAL PRICES

San Francisco, June 27.

Antimony, cents per pound.....	29
Electrolytic copper, cents per pound.....	29.50
Pig lead, cents per pound.....	7.25—8.25
Platinum: soft metal, 10% iridium, per ounce.....	\$75
Platinum: hard metal, 10% iridium, per ounce.....	\$79
Quicksilver: per flask of 75 lb.....	\$85
Spelter, cents per pound.....	15
Tin, cents per pound.....	43
Zinc-dust, cents per pound.....	30

ORE PRICES

San Francisco, June 27.

Antimony: 50% product, per unit (1% or 20 lb.)....	\$1.25
Chrome: 10% and over, f.o.b. cars California, per ton.....	12.00—14.00
Manganese: 50% product, f.o.b. cars California, ton.....	20.00
Manganesite: crude, per ton.....	7.00—10.00
Molybdenum: 50% and over, per pound.....	0.60—1.15
Tungsten: 60% WO ₃ per unit.....	30.00—35.00

Tungsten producers and dealers at Boulder, Colorado, are more hopeful of the market. W. M. Long is paying \$30 per unit to lessees, and \$25 at the mill for other concentrate. The Boulder Tungsten Production Co. is buying from lessees at \$10.

A moderate amount of business has been done in New York from \$30 to \$35. Russia is reported to be a buyer at slightly over \$30. France has been seeking to buy in the United States, Japan, and South America, despite a statement that she has a maximum price of \$13.50 per unit.

Silica bulletin of the U. S. Geological Survey is available. During 1915 the average price of quartz was \$3.20 per ton for crude and \$10.50 for ground, \$18.60 for tripoli, and \$8.40 for diatomaceous earth.

Gypsum prices averaged \$2.70 per ton in 1915.

EASTERN METAL MARKET

(By wire from New York.)

June 27.—Copper is dull, re-sellers making the market; lead is firmer on export enquiry; spelter is dull and easy.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.	Average week ending
June 21.....	61.25
" 22.....	65.00
" 23.....	66.87
" 24.....	66.12
" 25 Sunday.....	65.75
" 26.....	66.00
" 27.....	65.49
Monthly averages	
Jan. 1914. 1915. 1916.	1914. 1915. 1916.
Jan. 57.58 48.85 56.76	July 54.90 47.52
Feb. 57.53 48.15 56.74	Aug. 54.35 47.11
Mar. 58.01 50.61 57.89	Sept. 53.75 48.77
Apr. 58.52 50.25 61.57	Oct. 53.12 49.40
May 58.21 49.87 74.27	Nov. 49.12 51.88
June 56.13 19.02	Dec. 49.27 55.34

The movement of prices has been upward but sensitive. When large quantities of silver are purchased in England and Europe for coinage, and there is a lack of competitive buying and sales from India and China, the price recedes somewhat. The large requirements of the mints practically guarantees producers a good price for their metal. Stocks in London are 6,550,000 fine oz., a large part of which is immobile.

If war commences between the United States and Mexico about 25% of the world's production will be unavailable.

A 15c dividend has been declared by the Tomopah Mining Company.

May 3.80 4.41 7.38	Nov. 3.68 5.15
June 3.90 5.75	Dec. 3.80 5.34

The U. S. S. R. & M. Co. has declared \$1 per share on common and \$7½c on preferred stock.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, according to quantity. Prices, in dollars per flask of 75 pounds:

Date.	Week ending
May 31.....	73.00
June 6.....	72.50
Monthly averages	
Jan. 1914. 1915. 1916.	1914. 1915. 1916.
Jan. 39.25 51.90 222.00	July 37.50 95.00
Feb. 39.00 60.00 295.00	Aug. 80.00 93.75
Mar. 39.00 78.00 219.00	Sept. 76.25 91.00
Apr. 38.90 77.50 141.60	Oct. 53.00 92.90
May 39.00 75.00 90.00	Nov. 55.00 101.50
June 38.60 90.00	Dec. 53.10 123.00

Good sales of quicksilver have been made to England and Japan. The revival of export business in this metal and reduction of local stocks tends to higher prices.

ZINC

Zinc is quoted as spelter, standard Western brands, New York delivery, in cents per pound.

June 4.84 22.20	Dec. 5.40 16.75

The New Jersey Zinc Co. has reduced prices of its three high-grade brands by 8c, per lb., namely, from 25 to 17c, 24½ to 16½c, and 24 to 16 cents.

Eastern Metal Market

New York, June 21.

Quotations are lower, and the market dull in every metal but one—aluminum. Consumers of copper, zinc, lead, tin, and antimony appear to be waiting, marking time, as it were, to see what is going to happen. Meanwhile prices decline in the futile attempt to induce action.

The copper producers' quotations show evidence of softening, but up to the present second-hands are taking what little business there is. To a considerable extent the scarcity and inefficiency of labor is restraining consumption of the metals. Over 50 metal-working plants in and around Newark, New Jersey, are grappling with strikes. Common labor is so scarce that unskilled men can be fussy about what kind of work they do.

Zinc is neglected. The lead market is basing some hope on a revival of foreign business, but so far it has not materialized. Consumers of tin cannot be interested. Antimony is weak at 18 cents.

Aluminum, alone, shows an advance, credited to export buying.

Consumers, both domestic and foreign, are taking deliveries against their large purchases of recent months, and quiet is perhaps to be expected, but seldom has inactivity been so uniform in all the metals.

The steel trade continues to find less new business. A peculiar phase of the situation is that Bessemer steel is more easily obtainable than open-hearth, this applying to plates, shapes, and bars. Japan has been a large buyer of ship-plates, while Italy has been a large buyer of pig-iron. Russia is buying large quantities of metal working machinery in this market for manufacture of all kinds, largely automobile works and ship-yards. The domestic machinery market is quieter, with the demand for smaller tools predominating.

COPPER

Second-hands have continued to make the market in copper, but they have enjoyed but little business, with the exception of odd and scattered lots for which they have accepted 27c., cash, New York, where electrolytic was specified for prompt delivery. Lake is absolutely nominal at about 27.75c., although the price might be put at a lower level with safety. There is evidence that the producers are getting tired of the inactivity, and some of them, at least, are willing to sell at prices not much higher than those which re-sellers ask. The entire market is inconsistent. The one outstanding feature is the intense dullness. There is no new war business reported. The belligerent countries are staying out of the market presumably for the reason that they are now taking deliveries against their heavy purchases of a few months ago. As for domestic manufacturers, they are covered, in fact some of them have more copper than they need, especially in view of the unsatisfactory conditions which exist with respect to labor. Not only is common labor scarce, but once found it is inefficient and independent. Despite the fact that common labor is paid more than in years heretofore, workmen do not hesitate to leave employment for no other reason than that they find the work "too hard"—work which men in ordinary times are glad to do. The London market for electrolytic is dull, and the quotation is lower at £138 for spot (June 19). Exports from June 1 to 20 totaled 23,917 tons. The copper trade is, of course, watching the Mexican situation closely, but so far it has exerted little influence on conditions. It is conceded that should war be declared, production at several mines in Mexico might be suspended unless military protection were provided. The consensus of opinion is that it would not greatly increase the demand for copper.

ZINC

There is little to say except that buyers are not showing the least interest in the metal. A few small sales of prompt zinc have been made at 12.50c., New York, equal to 12.25c., St. Louis. Consumers seem determined that quotations shall dip still further before they take hold. July is to be held at about 12c., New York, August at 11.75c., and September at 11.30c., but futures are even more severely neglected than spot. The London market is steady, but inactive, at £68. Exports to the 20th total 2946 tons.

Sheet-zinc continues at 20c., carload lots, f.o.b. mill.

Dispatches from the Joplin, Missouri, district state that floods have caused many mines to shut-down, as was noted in the PRESS of last week.

LEAD

In the past few days the lead market has been tinged with hope based on a slight revival in export inquiry, coupled with the Mexican situation. But, the fact remains that prices have continued to decline, and that little business has been done, on either foreign or domestic account. The A. S. & R. Co. continues to quote 7c., New York, and 6.92½c., St. Louis, while independents are asking 6.62½c., New York, and 6.45c. St. Louis. Naturally the latter are taking what little business there is stirring. The sellers are in comfortable position in respect to their order books, but at prevailing prices they would be glad to book more business. Domestic consumers are well covered, however, and the war business has vanished. The London market is slightly higher at £31 7s. 6d. (as compared with a week ago). Exports for 20 days total 1798 tons.

TIN

Buying has been insignificant, and prices are lower. Spot Straits could be had yesterday at 49.75c., prompt delivery. The supply is more than ample, a fact of which consumers seem to be well aware. They also realize that the June shipments from the Straits Settlements will be extremely large, and that an over-supply may bring prices down to a still lower level. Until the market steadies itself activity cannot be looked for. The London market is weak, also, that at the Straits. London dropped £4 today, (June 21) making the quotation £174. The market has been dull for about 7 weeks, and the end is not in sight. Arrivals, up to the 20th totaled 3350 tons, and there was afloat on that day 3877 tons. The encouraging feature of the situation is that consumption in this country is on a great scale. Tin-plate mills are filled with orders, most of them to the end of the year. No other item in steel is so active.

ANTIMONY

The bottom has dropped out of the antimony market. Efforts to sell to uninterested consumers has brought the quotation for Chinese and Japanese grades down to 18c. per lb. Foreign buying is not in evidence. Some makers of antimony face heavy losses, for they cannot manufacture at prevailing prices. In many quarters it has been felt that ordinary grades of antimony, usually worth 5 to 7c. per lb., have been entirely too high.

ALUMINUM

Good buying by Russia and Italy is credited with having stiffened the aluminum market, with the result that 63 to 65c. is now asked for No. 1 virgin metal, 98 to 99% pure.

ORE

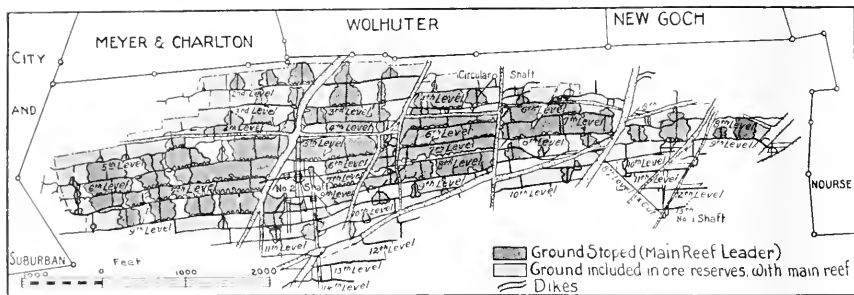

Antimony: It is reported that South American ore is no longer offered. To do so would be unprofitable in view of the low price of antimony and the high ocean freights.

COMPANY REPORTS

CITY DEEP, LIMITED

This Rand company will be remembered as one at whose mill several metallurgical experiments were made, chiefly in crushing. During 1915 there were 150 ordinary and 4 Nissen stamps operated, also 8 tube-mills, reducing 677,200 tons of ore. This averaged \$9.763 per ton, of which 66.4% was saved by amalgamation. The cyanide works treated 678,160 tons of sand and slime assaying \$3.313 per ton, with 85% extraction. A Butters filter-plant was ordered. The combined actual recovery of gold was 95.3%, against 96.3% by assay, according to the manager, Percy W. Sherwell. The year's revenue was £1,306,945, of which £624,632 was profit. Dividends absorbed £421,875. The balance for 1916 was £206,948, compared with £140,147 from 1914. Working costs were \$4.90 per ton. In 1914 the profit from 505,300 tons was £104,835, so that the past year showed a great improvement. There were 4708 natives employed.

At the mine, a section of which is shown herewith, development totaled 27,301 ft. The circular shaft is 2271 ft. vertical. Of the footage, 66% was in 'reef' formation as follows: Main Reef, 45 in. wide, worth \$3.30 per ton; Main Reef Leader,

UNDERGROUND WORKINGS OF THE CITY DEEP MINE ON THE RAND.

27 in. and \$21.10; and South Reef, 29 in. and \$14. Of the 784,150 tons mined last year, the Main Reef supplied 29%, and the Leader 71%. There was 13.5% discarded as waste. Reserves, according to the consulting engineer, E. H. Clifford, are estimated at 2,976,000 tons, worth \$9.50 per ton, an increase of 465,000 tons. The sand-filling of stopes is a success.

DOMO MINES CO.

This is one of the large companies operating at Porcupine, Ontario, and its report covers the year ended March 31, 1916. The general manager is C. D. Kaeding, with C. W. Dowsett as metallurgist. The grade of ore increased by 82c., ore treated was 99,090 tons more, and costs were 13.6c. per ton lower than in the preceding period.

Development totaled 17,359 ft., not including 5654 ft. of diamond-drilling. Exploration was fairly evenly distributed on the five main levels, with a zone 2000 ft. long, 400 ft. wide, and 700 ft. deep. Through the knowledge gained selective mining can be done, and 783,792 tons of unprofitable material was cut out of reserves. Reserves are estimated at 2,600,000 tons assaying \$6.20 per ton. On No. 7 level the stoping width shown by the first crosscut is 220 ft. On No. 5 and 6, near No. 2 shaft, there is 120 ft. width of \$6.50 ore. Two new wide zones are being developed on No. 7. The new main shaft was completed to a depth of 877 ft. All development cost \$307,000, or 60c. per ton. Mining cost 62.1c. per ton.

The mill treated 347,640 tons, yielding \$5.117 per ton with 92.88% recovery. Of this 59.04% was by amalgamation, and 33.84% by cyanidation. This is an increase, while costs decreased to 91c.

All operating charges amounted to \$2.559 per ton. From the revenue of \$1,778,959 there remained \$912,380 profit. Three dividends absorbed \$600,000. The year commenced with a balance of \$665,099, and ended with \$602,560. To bring the mill's capacity to 45,000 tons per month it was decided to add two Hardinge ball-mills (to replace 10 stamps), two tube-mills, two Pachuca agitators, three Dorr thickeners, two Merrill filter-presses, an air-compressor, hoist, head-frame, etc., the whole to cost \$282,514.

CANADIAN MINING CORPORATION MINING CORPORATION OF CANADA

The first of these concerns is an English company holding 1,911,319 shares of the 2,075,000 in the Canadian operating company. Out of dividends received from the Mining Corporation the English company distributed 30c. per share, or \$460,000 in the year ended March 31, 1916. The balance for the current-year is \$58,000.

The Canadian company owns an area of 183.5 acres in the centre of Cobalt, including the Cobalt Townsite, Townsite Extension, Cobalt Lake, City of Cobalt, and Little Nipissing

mines, also treatment plants. The consulting engineer is D'Arcy Weatherbe, and general manager, C. E. Watson. The report for the calendar year 1915 covers 44 pages, not including plans and photographs, and contains much of interest.

There was an average of 426.4 men employed at all properties, who worked a total of 133,776 shifts. Development amounted to 15,816 ft., at \$12.06 per ft., and 565 ft. of diamond-drilling. In 309.5 working days an average of 57.4 machine-shifts was worked per day. Stopping continued in the Townsite mine, and a good deal of new ore was opened, but in the west or Keewatin formation only a small area is available for exploration. In the Cobalt Lake mine the most important results obtained were along the Cobalt Lake fault, which penetrates both the conglomerate and Keewatin formations. On three levels long drifts were driven, finding some rich shoots, largely of argentiferous niccolite. Cobalt lake was drained during the year, using 5 centrifugal pumps with capacities of 450 to 700 gal. each per minute. This occupied 29 days. From April 12 to December 31, 1915, the cost of this work, including keeping the lake empty, etc., was \$25,598. The idea of this work was to render accessible ore under the lake. Present work on the Fault vein in the Cobalt Lake mine gives promise of finding more ore, but the future will probably depend on results of exploration in the north end of the property. Recent drilling proves that the underlying conglomerate is probably the deepest in the Cobalt district. Most of 1916 will be occupied in completing the work planned in this ground. Reserves

total 101,135 tons of ore, containing 3,937,995 oz. of silver, a small decrease. In the City mine are 2,312,425 oz., a large increase; 217,660 oz. in the Lake, a decrease; and 1,407,910 oz. in the Townsite, also a decrease.

The Cobalt Lake and Cobalt Reduction plants treated a total of 132,879 tons of ore, yielding 2,922,384 oz. of silver; from the 1026 tons sent to smelter the return was 1,641,574 oz., making a total output of 4,563,957 oz. The mill recovery was 90.72%. Cobalt sold amounted to 309,779 lb. The output of silver to date is 18,671,599 oz. The percentage of extraction by cyaniding ore slime and concentrate slime was 74.93.

Costs in 1915 for all departments were \$10.15 per ton and 29.57c. per oz. of silver, against \$9.16 and 30.91c. in 1914 respectively. In the latter period operations were for 9 months. The total income was \$2,632,682. The average price received for silver was 52.53c. per oz. The profit was \$1,284,141. Dividends absorbed \$518,750. The balance carried forward was \$674,645, making a total on hand at the end of 1915 of \$1,167,376.

Since April, 1914, there have been 124 properties considered, of which 70 were examined. Of the total 100 were gold, 12 silver, 5 copper, and 3 molybdenum.

The Cobalt Reduction Co.'s plant showed marked increased efficiency, raising the recovery from 80.94 to 86.51%. This was due to improvements in milling and cyaniding introduced by Mr. Fairlie. Table concentrate, 775 oz., is re-concentrated to much higher grade, namely, 2000 oz.

LENA GOLDFIELDS, LIMITED

This company controls the Lenskoie company, which operates an extensive placer mine in Siberia. The report dates with the year ended September 30, 1915. The revenue from sales of Lenskoie shares, and dividends from same, Russian bonds, royalties, loan, interest, repayment of advances by Lenskoie, and cash balance totaled £1,828,174, against £1,469,202. (The head office is in London). The net profit was 880,454 rubles (1 ruble = 50 cents), and a dividend of R.1.25 per share was paid on 1,158,297 issued. The balance to 1915-'16 was over £250,000 greater than for 1914-'15.

The consulting engineer, C. W. Purington, reported as follows: The gold recovery increased by \$5.68 per yard over the 1913-'14 result, due to improvements in washing, etc., using American methods. At the four mines 974,234 cu. yd. was washed, yielding 479,937 oz. gold, valued at £1,791,944, equal to about \$9.25 per yard. Including the gold from all sources the total value was £1,966,388, or \$9,450,000. The output to date is \$201,600,000. While the costs for 1914-'15 are not known yet, the future charges are assumed at \$6.84 per yd. Reserves are estimated at 2,238,850 cu. yd., averaging \$8.08 per yd., and 1,821,200 yd. probable, assaying \$5.32 per yd. Dredging is to be tried in the Bodaiho division, where 16,000,000 yd. exists. Further drilling is underway at that point. Costs should not be higher than in American dredging areas with similar climatic conditions. In the Nigri division is 5,200,000 yd. of gravel available for hydraulicking, worth 46c. per yd. Some preliminary washing was done there last year. The Bulbuka tributary contains 4,000,000 yd. of 5c. gravel. Winter washing was carried on successfully with the temperature at 75° F. below zero. Further electric power is to be developed. Horses were used less, and the efficiency of men increased. The War had little effect on operations.

During 1915 the Greene-Canea Copper Co.'s properties yielded 13,547,755 lb. of copper, 536,657 oz. of silver, and 3285 oz. of gold. The net income from all sources was \$1,362,606. Dividends absorbed \$500,000. The balance was \$862,606 against a deficit of \$384,208 in 1914. The continued revolution in Sonora was most annoying to the company. In spite of the small amount of development done, the ore opened undoubtedly exceeded that extracted, and there were notably larger ore reserves at the end of the year than when work resumed.

Book Review

ELEMENTS OF MINERALOGY. By Frank Rutley, revised by H. H. Read, with an introduction by G. T. Holloway. 19th edition. Thos. Murby & Co., London, and D. Van Nostrand Co., New York, 1916. P. 394. Ill. index. For sale by the MINING AND SCIENTIFIC PRESS. Price, \$1.25.

Before the present revised edition was prepared this useful little work had 18 separate printings, 13 during the author's life. Owing to the advance in the subject during recent years, and the number of appendices added to former editions, alterations in the new work were deemed necessary. Some pertinent remarks as to the association and value of minerals is given in the introduction. After a perusal of Part I, which includes the chemistry, optical and physical properties of minerals, crystallography; and Part II, describing the mineral species, we can safely recommend this as a useful and practical book, and quite up-to-date. A note is given on flotation of minerals. In a glossary of terms used in economic geology are to be found secondary enrichment, gossan, magmatic segregation, metamorphism, sedimentary rocks, tuff, and others frequently read in technical journals.

Every topic of importance to the Americas was discussed at this Congress, this volume being a record of the proceedings.

In a neat booklet of 32 pages, 3 by 6 in., bound with 'Faberloid,' the Dr. Pohl Fabrikoid Co. of Wilmington, Delaware, discusses 'book finish.' Leather is scarce, and an artificial product is necessary for books, automobiles, furniture, etc. Fabrikoid has proved that it wears well, and many book firms are using it. The material is water-proof and washable, also vermin-proof.

INDUSTRIAL NOTES

Information supplied by the manufacturers

The Kraut-Kollberg Flotation Machine

By MAX KRAUT

This machine was invented and designed by Mr. Kollberg and myself at Bisbee, and since has been tried successfully at various other places. Patents on the machine have been granted and others are pending. Disregarding the metallurgy of flotation, the working principle of this machine stands in striking contrast to both the agitator and pneumatic types of flotation apparatus. While the former effect the aeration of the pulp by agitating and churning, and, so to speak, beating the air into it, and the latter by blowing air under pressure through a porous medium into the pulp, the K & K machine effects the aeration by an original device, as simple as it is effective. The machine consists essentially of a long, hollow, cylindrical drum, mounted on a horizontal shaft. This drum is provided with a series of longitudinal air-slots and a larger number of longitudinal riffles running the entire length of the drum. The drum is rotated rapidly inside of a close-fitting casing, the whole being enclosed in a suitable housing, as shown by the accompanying illustration. A discharge-lip

SKETCH OF THE KRAUT-KOLLBERG FLOTATION MACHINE.

placed tangentially to the periphery of the drum provides for taking the pulp into the frothing-box and a controllable intake passage at the bottom of the frothing-box provides for returning the pulp to the aeration-chamber for re-treatment.

The operation of the machine will be best understood by following the pulp as it enters. The oiled pulp enters the aeration-chamber by the feed-pipe. As soon as the level of the pulp rises inside the aeration-chamber so as to touch the periphery of the rapidly revolving drum, it is taken up, partly by the adhesion of the pulp to the surface, partly by the skimming action of the riffles; it is taken around and immediately discharged by centrifugal force over the discharge-lip into the frothing-chamber. But any fluid moving at great speed in an enclosed passage has the tendency to produce a vacuum while in such passage and thus induce air-suction if the passage has a proper connection with the outside air. The pulp is moving in a thin layer at great speed in the narrow space between the periphery of the drum and its casing, and hence has the tendency to create a vacuum and thus induce suction, the air being drawn through the slots from the inside of the hollow drum. In turn, the inside of the drum is supplied with air through the open boxes through which the shaft passes at the two ends of the machine, as is plainly shown in the illustration. A further aeration of the pulp is effected by the suction induced by the jet or spray of the pulp

thrown off the periphery of the drum by centrifugal force at the point of discharge. The pulp, thus thoroughly aerated, enters through a number of holes which cause it to spread over the entire area of the frothing-box. The mineral froth rises to the surface and discharges over the edge of the box into a launder while the pulp settles down and again enters the aeration chamber for re-treatment through passages, the openings of which are controlled by a sliding gate. These openings are so adjusted that the pulp in the aeration-chamber can never rise above the level where it touches the periphery of the drum, thus assuring a perfect aeration at a minimum expenditure of energy, as in this manner an unnecessary and power-consuming agitation, churning, or beating of the pulp is completely avoided. The tailing is discharged through a pipe, the discharge being regulated automatically by a level-control, so as always to maintain the same pulp-level in the frothing-box. It will be seen that, as the new feed enters the machine at one end, and the tailing is being discharged at the other, the pulp gradually advances from the head toward the tail of the machine, describing in its course a spiral, as it is being re-treated repeatedly in the aeration-chamber and discharged into the frothing-box. A direct flow of pulp from the head end toward the tail end is prevented inside the aeration-chamber by rapid cross-currents, which prevent longitudinal currents, and in the frothing-box by a number of partitions, thus forcing the pulp to undergo a series of successive treatments as indicated. Except the tailing-discharge valve, which is controlled automatically, there are no other valves to be regulated or adjusted (the bottom gate being set only once); therefore the machine is self-regulating and requires no attention beyond keeping the bearings oiled properly.

The automatic-level control consists of an overflow arrangement attached to the tail end of the machine in such a way that by means of a sliding gate the overflow-level can be set at any desired height. As soon as the level in the frothing-box rises above the edge of the overflow-gate, part of the tailing overflows into a suspended bucket, which at its bottom is provided with a $\frac{1}{2}$ -in. hole. When the overflow becomes so great that the inflow into the bucket exceeds its discharge, the bucket gradually fills with pulp and begins to exert a pull on a wire or string connected to the end of one arm of a lever, the other arm of which actuates a plug or gate controlling the tailing-discharge. In this manner, whenever the level in the frothing-box rises it causes the gate or plug of the tailing-discharge to be opened. When the level sinks below the overflow edge, the overflow ceases, the bucket empties itself and the discharge-gate closes. But now it is apparent that whenever the force exerted by the weight of the bucket becomes great enough to move the discharge-gate, it will do this not gradually but will open the gate completely at once. This would cause the mechanism to open and close the gate continually, with accompanying fluctuations of the pulp-level in the frothing-chamber. To overcome this difficulty, one arm of the lever is attached to a mercury dash-pot, that is, a hollow-iron weight suspended in a pot of mercury. The hollow weight is provided with a small hole at the bottom, which permits the mercury to run in and out on very slowly. When now the bucket at the other end of the lever is exerting a pull, the mercury inside the hollow weight counter-acts the pull, gradually diminishing in force as the mercury slowly runs out of the hole. The reverse action takes place when the level sinks below the overflow edges. The mechanism is sensitive to fluctuations in the quantity of feed and readily adjusts the discharge-opening to correspond to any variations in the feed automatically, and thus contributes to the ease and facility with which this machine can be operated.

The WESTERN ELECTRIC Co. announces the death of Enos M. Barton, one of its founders, and for 20 years its president, on May 3, at the age of 72.

EDITORIAL

T. A. RICKARD, Editor

ON September 25 and following days the second National Exposition of Chemical Industries will be held in New York.

SILVER has been steady lately, at about 65 cents per ounce, with a tendency to rise. We note that *The Statist* estimates the production of Mexico in 1915 at 55,000,000 ounces, as against 70,703,828 in 1913. We question the figures for last year, believing that the reduction of output was more than is indicated by our London contemporary. By the way, the Real del Monte discovery has not yet become a source of production; it awaits further development.

SODIUM SULPHIDE is a chemical for which there is likely to be a demand, in ton lots, in consequence of the new use of it in the sulphatizing of oxidized lead and copper ores preparatory to flotation. As a by-product, it can be made profitably at soda works and similar chemical manufacturing plants, if only a demand for it becomes established in connection with flotation. Incidentally, we note that the Nipissing company is about to use sodium sulphide as a precipitant for silver in cyanide solutions, in place of aluminum, the price of which has been doubled by the demand created during the War.

LAST week we published an article on the theory of flotation; it came to us from Korea and was written by Mr. H. Hardy Smith, who explained the physical forces governing the formation and behavior of bubbles, on the basis of his work at the Suan mine. In this issue we give our readers the greater part of a paper by Mr. Robert J. Anderson, Instructor in Metallurgy at the Missouri School of Mines. This paper is to be read at the forthcoming meeting of the American Institute of Mining Engineers in Arizona; it reviews the state of the art in a useful way, touching upon the obscurities that perplex the student and operator in this new branch of metallurgy. It will be noted that Mr. Anderson refers to several articles that have appeared in our pages.

THE BIGGEST thing of its kind always attracts popular interest. We note that Mr. D. C. Jackling, in an interview, places the Chuquicamata as the biggest copper mine in the world, having regard to its present development and future prospects; he places the Utah Copper second, and the Braden third. For the time of a generation the Rio Tinto was the premier copper mine of the world, but during the last decade the development of the disseminated copper deposits and of the two Chilean properties has changed our standards of mag-

nitude. The Rio Tinto has been credited with a reserve of 100,000,000 tons of 24% ore. This was considered colossal ten years ago, but the Chuquicamata is credited with four times as much ore of about the same grade.

MOST of the cyanide used on the Rand, at the rate of 5000 tons per annum, worth about \$2,500,000, is now obtained from Glasgow. At the beginning of the War the British government arranged for a supply at a price of 17 cents per pound, which was 3 cents above the ante-bellum cost. It is announced that a new contract has been made between the principal mining groups operating in the Transvaal and Rhodesia by which a supply of cyanide is assured for five years from the Cassel Cyanide Company, of Glasgow, together with a minor proportion from the British Cyanide Company. Fortunately for the Rand and other goldfields, the restriction of silver mining and milling in Mexico has reduced the demand for cyanide from that country, the treatment of a silver ore requiring about four times as much cyanide as a gold ore.

HOW low-grade is the gold ore milled at Juneau, Alaska, is not fully appreciated. For example, the Alaska Gold Mines Co., during its ten months of operation in 1915, recovered only 94 cents per ton from 1,115,294 tons of ore, obtaining therefrom 23 cents profit per ton. Miners are accustomed to think of the copper and iron ores of Lake Superior as being the last word in low yield of metal, but a 30-ton earload of 1% copper from a Lake Superior mine contains 600 pounds of copper worth \$90, with copper at 15c. per pound, and in recent times nearly twice as much. A 30-ton earload of iron ore is worth at least \$60 at the mines and \$100 at Lower Lake points. On the other hand, a 30-ton car of \$1 gold ore can never have an assay-value of more than \$30. It is interesting to note that the three mines of the Treadwell group on Douglas island extracted nearly \$2 per ton from the 1,652,307 tons of ore treated in 1915; of this about 80 cents per ton was profit.

ZINC is being produced at the Butte & Superior mine, in Montana, at the rate of 90,000 tons per annum. This is more metal than is produced by the Utah Copper mine, just now the most productive copper mine in the world. The Butte & Superior company extracts this amount of zinc, as a concentrate, from about 650,000 tons of ore, while the Utah Copper company last year treated 8,494,300 tons of ore to obtain 78,103 tons of copper. At the zinc mine, the ore averages about 17%, while at the copper mine the average yield of metal is only 1.5%.

Ordinarily copper is three times more valuable than zinc, but in 1915, in consequence of abnormal conditions, the average price of spelter at St. Louis was 13 cents, while the copper of the Utah Copper company during that year was sold for 17.679 cents per pound. In 1914 spelter averaged only 5 cents, while copper averaged 13.31 cents per pound. In 1914 the production of spelter in the United States was 353,049 tons. The present output of the Butte & Superior is equal to one-quarter of the country's annual production before the War.

PAPER is becoming scarcer and more expensive. As a means of reducing this country's enormous consumption of paper, *Life* suggests that advertising by means of circulars be curtailed, as scarcely anybody reads them since the flood of them has become so great. A further hint is the reduction of unnecessary periodicals. Nearly every institution, organization, and cause publishes a periodical of some sort. Some of them are useful mediums, interesting to various kinds of intelligent people, but "about a million of them," says *Life*, "could be stopped entirely and no one would ever miss them." The *Congressional Record* and *G. A. R. Journal* are mentioned, and there are a great many more. Publicity for any cause, cut down to its proper proportion, can be obtained through the established periodicals. Meanwhile, if waste paper, that is paper that has served its purpose whether for wrapping or reading, were collected and saved for re-manufacture, the consumption of a national resource, wood-pulp, could be lessened considerably.

DISCUSSION this week covers a variety of topics. The first contribution asks a timely and pertinent question: "Why ship concentrate?" This is exactly what a number of managers would like to know, particularly on the Mother Lode and in the Tonopah-Goldfield region. Mr. William Macdonald, a mill-superintendent, who has had much experience in Australia, New Zealand, and Nevada, quotes the method in vogue at the Waihi Grand Junction mine, which is next-door to the famous Waihi mine, in New Zealand, and has been conspicuously well managed by Mr. W. Frank Grace. Next comes a letter on a subject discussed recently in our editorial columns. Mr. Curt N. Schmette writes frankly, and in the vernacular; we are glad to record this personal experience of a young man serving his apprenticeship in the profession, and we commend it to the serious attention of educators and managers. Many of our readers, particularly the veterans, will be pleased to see the honored name of Mr. Richard Pearce at the bottom of a note on 'Uraninite in Colorado.' We wrote to Mr. Pearce asking him to correct a recent sensationally inaccurate account of his discovery of pitchblende in Gilpin county; hence the letter and the re-publication of an article on the subject from the proceedings of the Colorado Scientific Society. Mr. Pearce's many friends in the West will be glad to know that he is living near Liverpool, where he and one of his sons, Mr. Frank Pearce, have established a successful tin smelter. The

account of his discovery of this rare mineral, uraninite, 45 years ago, suggests that Mr. Richard Pearce is in the evening of life, but we are glad to say that he retains all his old interest in minerals and metals, and men.

IT looks like another veracrusade. General Pershing has withdrawn his force three-quarters of the way home. General Trevino has surrendered the troopers captured at Carrizal, and Señor Carranza has made an evasive reply to our Government's latest ultimatum. The chances are that the present crisis will pass without war, but it bears the seed of further friction. The *de facto* government of Mexico is incapable of restoring order, and recurrent clashes along the frontier are certain. The Mexican muddle is no nearer a settlement, nor is a settlement likely until the United States, by consent or by force, intervenes.

The Gold of the Banket

An ore deposit provokes interest commensurate with its richness, that is, its content of valuable metal. We speak for the mining engineer. To the academic geologist the purely economic phase may seem less insistent than eccentricity of structure or abnormality of occurrence. It is no wonder therefore that the gold-bearing conglomerate of the Witwatersrand continues to attract technical study and scientific investigation, because the Rand, as it is called for short, produces 40% of the world's annual output of gold. Another reason for continued interest in the subject is the fact that the origin of the gold in these deposits has not yet been explained satisfactorily. No monographic official treatise of a kind comparable with those published on the Comstock, Cripple Creek, Pzribram, or Bendigo has been issued. We have had, it is true, a number of papers by mining engineers and another set of writings by geologists, but these cover various aspects of the problem without the co-ordination characterizing a single, complete and systematic investigation. Hence we are not surprised that the Institution of Mining and Metallurgy—it should be unnecessary to add, in London—gave a cordial welcome to the paper presented by Mr. E. T. Mellor, of the Transvaal Geological Survey, on the subject of 'The Conglomerates of the Witwatersrand.' We have read this essay of 62 pages and as much of the discussion as has been printed. Undoubtedly it will take an honorable place in the bibliography of South African economic geology. It represents the result of five years of conscientious work by a capable observer. Mr. Mellor's main conclusions are (1) that the gold is not confined to the beds of conglomerate now being mined, but is distributed throughout the Witwatersrand system, which is a series of sedimentary beds fully 20,000 feet thick; (2) that the extraordinary persistence of the individual beds constituting the lodes now being exploited—such as the Main Reef Leader—is due to their having been laid down in extensive deltas. Although he recognizes the probability of a re-distribution of part of the gold deposited mechanically with the conglomerate, and does

not ignore solution and re-precipitation as factors modifying the richness of the banket as an ore deposit, he concludes that the Main Reef Series represents a fossil placer. In his analysis of the conditions that must have governed the formation of these extensive beds of conglomerate, he brings to bear a large mass of evidence of an impressive kind; in short, his work as a stratigrapher is convincing. He explains the origin of the conglomerate satisfactorily. Next comes the harder problem, that of the origin of the gold associated with the conglomerate and to which it owes all its economic importance. This phenomenon, or appearance, has puzzled veteran scientists much as the milk in the cocoa-nut or the fly in the amber nonplussed the small boy. Mr. Mellor proceeds to argue that the concentration of the gold in certain particularly well-defined and continuous beds coincides with, and is probably the result of, special conditions of sedimentation; and even the distribution of the gold within these individual beds of conglomerate is considered by him attributable to the manner in which these sediments were laid down in pre-Cambrian time. He finds analogy between the Rand delta and the Nome coastal plain, which is not unreasonable, as regards processes of sedimentation, but he fails to note the entire unlikeness between the marvellous concentrations of gold constituting the raised beaches—the real fossil placers of Nome—and the broad area of low-grade conglomerate constituting the Rand. Again, he compares the pre-Cambrian conglomerate in the White Waters Range of the Transvaal with the Cambrian conglomerate in the Black Hills of South Dakota, and not without warrant, but he ignores the fact that while the Dakotan conglomerate contains gold some of which was derived, by erosion, from the Homestake vein, it is also true that the main enrichment of the latter is associated with thermal activity accompanying the intrusion of rhyolite in an early Tertiary period. However, this is not the place for detailed criticism. Another interesting feature of Mr. Mellor's presentation of the subject is his insistence on the sedimentary origin of the gold while acknowledging the later deposition, from thermal waters, of most of the pyrite and all of the other sulphides, found particularly in the younger quartz veins that cross the conglomerate beds. Obviously, the last word has not been said. The modification of the Becker-Gregory theory of a marine deposit along a subsiding shore and the substitution of a deltaic deposition is interesting, but it is not conclusive as regards the origin of the gold itself. The pyritic nodules that bothered Mr. G. F. Becker have been dissected by Mr. C. Baring Horwood in the admirable investigation described at length in the MINING AND SCIENTIFIC PRESS during 1914. The absence of ore-shoots, claimed as an argument against the theory of a lode formed by infiltration in the usual way, is not brought forward by Mr. Mellor. Indeed, the idea of uniform dissemination suited the exigencies of Rand finance better than it fits the facts as disclosed by the mine workings. Of course, the placer theory lends itself to talk of indefinite persistence of ore better than the

lode theory, for if the banket be an indefinitely huge layer of pebbles, sand, and gold, all of sedimentary origin, then it is *hors concours* indeed. But we doubt it, and suggest that before coming to a confident conclusion it will be well to study the known gold-bearing conglomerates of Nova Scotia, South Dakota, Alaska, California, and Queensland. Mr. Mellor has read about some of these; and his paper gains by his references to them. At least he has escaped the provincialism that claimed the Rand deposits as unique. The idea that any ore deposit is a special creation is unscientific. On the contrary, he will probably agree with us that every ore deposit must be studied in the light of the knowledge extant concerning kindred phenomena elsewhere.

The First Half of 1916

With commendable promptitude, the Geological Survey issues a review of the mineral industry during the first six months of the current year. "The mining man is having his innings" is a phrase that summarizes this timely appraisal of progress. The production of gold is reported as a little short of last year, but silver is being produced at a rate likely to break all previous records. The production of copper has responded to an average price, during the six months, of 26 cents per pound, so that the rate of increase noted in 1915 has continued into the current year. Arizona will maintain its first place, thanks to the splendid work being done at the Inspiration mine, among others. In Montana the total of all metallic products shows a 60% increase. Colorado has increased its copper output—which is small—by 30%, with gains in lead and zinc also. In Utah the copper produced will have a value twice that of 1915. Similar optimistic summaries come from Idaho, Nevada, and Alaska, but it is unnecessary to repeat them, our own pages having recorded progress week by week and month by month. We regret that the Director of the Survey is unable to give more precise information; his review is too evidently adapted for the daily press, which enjoys glittering generalities. However, this official dictum concerning the prosperity of the industry is intended for those detached from mining. Any observant traveler in the West during the last twelve months will have noted the many signs of expansion: cars of ore on remote railroad-sidings; old mills being re-modeled and re-fitted; the smoke rising from smelters lately idle; pack-mules passing down abandoned trails; the freight-train loaded with machinery; the refineries choked with mine products; the ships being loaded with refined metal; the engineers on their way to examine mines; and the speculator eager to talk about the price of metals. Indeed, we scarcely needed an official recognition of the fact that the mining industry of the West is thriving as never before; and, what is equally important, our pages testify to the re-awakening of technical ingenuity in the devising of new processes and the trial of new ideas in every branch of the industry. If all goes well, 1916 will be a year to make the American miner glad and grateful.

Our Economic Bronze Age

It is prudent to give serious thought to the perils of peace while the known safeties of war are still about us. Men suffered through a generation of armed peace, enduring economic hardships, poor wages, cut-throat commercialism, contracts that protected those rich enough to get such justice as suited their desires; it was a time when men feared war, and piled up armaments so massive and ominous that no one might dare to fight while everyone was equally prepared. Wise men beholding this enginery of destruction declared war impossible. It meant suicide, universal annihilation, the wiping out of the civilized nations, so that the world would need to start over again from the nucleus of surviving savages in the outer darkness of unpreparedness. The parrot world took up the refrain and 'peace the actual and eternal, war the impossible and abolished' became the chief article of faith among deluded nations. They did not recognize that we had progressed no further in genuine civilization than Isaiah, Epictetus, Luther, or Napoleon. The doctrines of pure morals and sound ethics have not been improved in any material aspect since the days of Augustus Caesar, nor have new and sounder economic bases of peace been discovered. The climax in human conceptions of the absolute moral was reached early, but the principles of a safe and sane peace have continued elusive. We are in the economic bronze age still, and many of us even reflect frankly paleolithic barbarisms of economic thought.

It was such a barbarism to think that peace could be maintained permanently by an armed menace without a mathematically exact balance of menaces. It was a similarly wild dream to think that the stimulus of enthusiasm for defense of country would awaken the dormant Mars in civilian breasts so as to match them equally and instantly against the trained millions of a prepared power. It proved a dream also, destructive of the beautiful theories of the wise ones who knew how to settle the affairs of men over their after-lunch cigars, incontestably and immutably determined, Q. E. D., to wit, that war was too destructive to be undertaken; and, when it was undertaken, that the *n*th term of the series of daily military vulcanisms necessary to destroy all Europe was thirty to guess at the extreme. Meanwhile others gained reputation for wisdom by building peace palaces; arbitration congresses fought over the way peace was to be maintained; and pacifist secretaries of state warred with non-militant presidents over the pungency of non-militant language used in explaining our pacific determinations.

The childhood of man has not yet passed away when these follies can be enacted in an epoch of armed and aggressive peace, when the struggle for trade supremacy is bolstered up by tariff walls, by subtle subventions, and by gross bonus systems, serving as the infantry of embattled commerce drawn up under cover of the artillery of protecting nations.

To affirm that armies, navies, great guns, militarism,

are all of the same breed with the economic devices whereby trade is stimulated for the sake of national aggrandizement, is no more ridiculous than the folly that would undertake to guarantee peace by treaty, and give a world-court authority over the nations without an obedient force, big enough to transmute that court into the most stupendous grafting oligarchy that the world has ever seen. When capitalists and college presidents and politicians of international fame give vent to such puerile notions we may be excused for an economic juvenility of our own, because, even if the realization linger down the centuries, the old system of tariffs and guns and artificial centres of trade and manufacture will keep us from the perils that a scientific basis of economic peace might involve if applied suddenly as a cure for the madness of nations. It may not come true any more than arbitration treaties that will stand, or international courts that will be cheerfully obeyed, will come true; not for years and centuries, perhaps, can this come to pass, and yet it must come true in the end if a man is to advance higher and bring his economic bread-getting existence up to a par with his intellectual conceptions of morality and right.

We are in the economic bronze age! Only copper is free—copper alone of the ordinary articles of commerce. It is strange when we reflect how other industries have been coddled, while copper has grown to be one of the dominant factors in trade and exchange, unsustained by tariffs and subventions. The bronze age points the way to the next step in our economic liberation. When shall we advance to the economic iron age, and thence into epochs of more difficult science in the preservation of industry in accordance with the conditions set by nature? Should trade be allowed to grow by a pact between exhausted belligerents and their supporters in the places and along the courses which by nature are favorable, rather than by virtue of stimulative laws sustained by arrogant militarism, then a police force—all the kinks and wrinkles having been smoothed out by experience—would be enough, just as it would be if all men were to be suddenly inflamed with religious zeal to obey an international court and abide by treaties of arbitration as the corner-stone of a world association of altruists.

This may not be taken wholly as a jest. In jesting mood and manner the wholesome truth may be thrown at an autocratic king. So may it be thrown at a too-proud and over-confident people, who may not pause to think how great were the folly of the fury and heroism of the European war if it should bring merely peace—only an empty peace, with the worms of national aggrandizement rolled up in it to consume both the written word and the parchment. This is something to ponder while the guns are booming, so that when the time comes to end the strife the world may have caught inspiration from the bronze age, and may set something else free besides copper; may establish new principles of free commerce, giving hope that the struggle has brought nearer the blessings of an economic peace. X.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Why Ship Concentrate?

The Editor:

Sir—The question of the local treatment of concentrate, especially in districts remote from railways and smelters, is one that claims the attention of many mining companies. At the present time there are several instances of concentrates being shipped, at heavy expense, although they could undoubtedly be locally treated to greater advantage. In my experience in this country and in other parts of the world there are few places where the raw concentrate is not amenable to treatment by cyanide. It is unlikely that any concentrate presents greater difficulties to successful cyanidation than that produced at some of the Mother Lode mines in California, but it has been shown in recent interesting articles in this paper and by the fact that there are numerous mines on the Lode successfully treating their raw concentrate that such difficulties are not insuperable. The amenability of a concentrate to cyanide treatment having been demonstrated, a possible field is opened up for treatment of the whole ore by similar methods, whereas preliminary roasting does not go beyond the disposal of the concentrate. This fact is of great importance in new mining regions and might affect the future of a district or lead to its more rapid development.

The Waihi mine, which was probably the pioneer in this branch of cyanidation has maintained an extraction of 95-96% of both the gold and silver contents of the concentrate over a period of 12 years. At this mine, in New Zealand, the concentrate presents no difficulty of a chemical nature, the chief consideration being extremely fine comminution of the particles and sufficient length of time of agitation to dissolve the silver content, which is high in proportion to the gold. At Atlanta, in Idaho, a concentrate is produced carrying 4% arsenic, besides antimony, lead, zinc, etc., in less quantities. In this instance serious difficulties were faced in starting cyaniding operations, but the raw concentrate is now being treated profitably. Success in this case hinged upon the fact that freight-charges to the nearest railway-point were excessively high, thus allowing a considerable margin for cost of treatment. Each concentrate presents its own particular problem, which may not be altogether a metallurgical one. Local conditions may be a deciding factor.

Assuming that the treatment of a concentrate in the raw state is a commercially sound proposition, the question next arising is the best method of dealing with it.

It is generally assumed that separate treatment of the concentrate to recover the valuable metals is the necessary procedure. Where the whole ore is cyanided this does not follow. At the Waihi Grand Junction mine, also in New Zealand, a novel system of dealing with the concentrate was introduced some years ago by F. C. Brown, the inventor of the Pachuca tank, and is still in successful operation at that mine. Various articles have been published dealing with this system (some of which are mentioned at the end of this article), but in my opinion it has not been given the consideration that it deserves by metallurgists in this country. Briefly stated, the system consists in placing the concentrating machines in circuit with the tube-mill and making use of them not to recover the concentrate but as an aid to finer reduction.

FLOW-SHEET OF THE WAIHI GRAND JUNCTION MILL.

The machines are placed in position to receive the overflow pulp from the tube-mill classifier. It is advisable in most cases to have intermediate cone-classifiers for the purpose of separating the bulk of solution or water and fine slime, thus avoiding overloading the concentrating machines with slime. The concentrate, together with what would usually be called 'seconds,' or just as much of this material as may be considered desirable, is collected in a common launder and elevated back to the tube-mill feed. In this way the coarser concentrate, together with the larger grains of sand, is repeatedly returned and re-ground until the concentrate is sufficiently fine to float off with the ore instead of settling on the

table. It then passes on, concentrate and pulp being treated together as one product. The essential features of the system are shown in the accompanying flow-diagram.

Separate treatment of concentrate makes crushing and concentrating in water compulsory, while the combination treatment can be carried out either in water or cyanide solution. Crushing in cyanide solution is usually the better practice for reasons well known to metallurgists and mill-men. It is certainly advantageous to carry out the operations of concentrating and grinding in cyanide solution, one advantage having a direct bearing on the system being that the strength of the cyanide solution can be kept as high as is necessary in order to attain the maximum extraction without undue loss in the form of waste solution.

The number of concentrating machines required is somewhat larger than would be ordinarily used on any given tonnage of ore crushed in proportion to the larger tonnage passing in the tube-mill circuit. The Wilfley or Deister type is the best for the purpose, as the concentrate can be more conveniently collected and continuously returned than in the case of machines of the Frue or Johnson type.

Some of the advantages of this system are obvious: (1) The process of treatment is simplified, there being only one product to handle instead of two, thereby reducing cost of operation. (2) Saving in first cost of installation of separate plant. (3) Improved metallurgical efficiency. The system results in an equal, if not higher, extraction at a less cost for cyanide and other chemicals and a more rapid dissolution of the gold and silver content than when separately treated.

The improved metallurgical efficiency is accounted for by the finer reduction of the concentrate, due to the abrasive action of the sand on the softer particles of concentrate and the fact that the particles of concentrate are separated one from another by sand, and thus kept from packing; also the high ratio of cyanide solution to concentrate. That the gold and silver content is brought into solution much more rapidly has been clearly shown at the Waibi Grand Junction. At this mine 80% of the total bullion content in the ore is in solution before the pulp leaves the concentrating tables, and 21 hours' agitation suffices to complete the treatment, whereas 8 to 10 days was previously required when treating separately. The decreased consumption in cyanide is brought about by reason of the fact that the use of a low-strength solution is made possible. The solution circulating in the mill where the system was first adopted is only 0.07% KCN and the extraction 90.9%.

It is not suggested that the system can be applied to ores indiscriminately, although the cases where it cannot be applied are few, outside ores and concentrates not amenable to cyanide treatment. If prolonged contact of the concentrate with cyanide solution is required, it becomes inadvisable to hold back the ordinary slime-treatment in order to extract metal from the concentrate, but due consideration must be given to the fact that a more

rapid dissolution of the bullion-content ensues than when separately treated. Where a tube-mill and classifier operate in closed circuit the heavier mineralized portion of the ore receives preferential treatment owing to its higher specific gravity, and in some instances the concentrate in the pulp coming from the classifier-overflow may be sufficiently fine to allow an economic extraction of the precious metals. As a rule, however, it is necessary to reduce the concentrate to a much finer condition, even to an impalpable slime, necessitating the use of concentrating machines as already described.

At mines where the method of treatment consists of amalgamation followed by concentration without fine-grinding or cyanidation of the whole ore, it follows that the concentrate must be treated separately or shipped to smelters, but it is a problem worthy of consideration by companies that may contemplate treating their concentrate, or that are at present doing so, whether it would not be worth while to go a step further and treat the whole of their ore by some such system as the one outlined. Where no further treatment of the ore follows concentration, the mineral escaping into the tailing is so much profit lost; and even if concentration is viewed as a fine art, it is still subject to inefficiency of machines and the vagaries of the personal equation. In cases where cyanidation of the whole ore follows concentration and the concentrate is shipped, argument in favor of a combined treatment would appear to be even stronger.

The above sketch of an exceptional procedure in connection with the treatment of gold and silver ores is brought forward because it undoubtedly has metallurgical merit and is being applied, in at least one instance, with marked success. So far as I am aware, it has not been applied in this country, but there must be many localities where it could be adopted successfully.*

WILLIAM MACDONALD.

Berkeley, June 5.

Mucking as an Educator

The Editor:

Sir—Being one of those who 'muck' during the summer vacation of the university, in order to gain experience and to accumulate some measure of filthy lucre, I would like to contribute a little first-hand experience, the gaining of which greatly increased my capacity for galgenhumor. I obtained my job by applying to the manager of a mining company whose product is quoted at twice its normal value since the War, and received the answer that they could make use of me if I were willing to work as a common laborer.

*The following articles and papers have appeared on this subject:

'Notes on Cyanide Treatment of Concentrate,' by A. Grothe. Proceedings of Mexican Institute of Mining & Metallurgy, August 1909.

'Cyanidation of Concentrate,' by F. C. Brown, M. & S. P., August 27, 1910.

'Fine Grinding,' by H. S. Denny. *Mining Magazine*, March 1911.

The first week I lived at the company's boarding-house, paying 75 cents per day for the privilege of sleeping in my own blankets on the springs of a bedstead, the mattress being supplied in theory only, as were nine-tenths of the panes in the window.

The place where I worked was a stiff 50 minutes walk from the boarding-house. My job was so exacting that I never managed to eat a single piece of bread from my lunch-bucket at one sitting.

Since the boarding-house furnished only three (mediocre) meals per day, and as I was required to work on night or graveyard shift exclusively, I seldom managed to get more than two meals per day (one of them a cold lunch I took along), which did not deter the company from collecting the full board-money each day. I then moved into a cabin, located nearer the place of my work, and 'batched' for myself, groceries, etc., being obtainable at the company store at the company's prices.

Near the boarding-house there was one shower-bath, which had hot water only when the oil-engines broke down and steam had to be substituted. At the camp where my cabin was, there was no shower-bath until I made one from an old tin-can and some pipe-fittings. This transformed my cabin into a public bath-room despite the assertion "Oh, if I build a shower up there you'd be the only one to use it."

It became necessary, in the course of human events, to lay a pipe-line through verdant growths of 'poison oak.' Seeing us covered from head to foot with the loathsome eezema, the manager facetiously remarked that we should have taken a salt-bath before starting in, the irony of which is apparent, there being no bath-tub within miles of the place. Then it was pompously announced that there was medicine for us "down at the office" and I was detailed to get it. It consisted of a 12-oz. can, half-full of carbolated ointment, which is painfully useless as applied to poison oak. This was distributed among five men and each man was charged \$1.75 for "doctor's treatment!" Considering the fact that I was only getting \$1.75 per day, and that none of us used the stuff, and that we never saw a doctor, and that it wasn't our fault that we had the malady, we felt considerably outraged.

Such privys as were on the place were a flagrant menace to public health, and were seldom, if ever, used.

The lone amusement, or diversion, of the place was a home-talent band, whose every effort lapsed into the familiar strains of 'Home Sweet Home,' no matter what they played.

The ambition of most men seemed to be to get out of the company's debt, and 'beat it.' To a single man this was practicable, but to a man with wife and children it meant a long struggle and privation, in addition to exposing his family to the prevalent unsanitary conditions. Other things that I heard on good authority and without solicitation convince me that if an employee of that company were to barter his soul to the devil, the company would receive a rake-off on the transaction.

Compared with Goldfield and other camps in which I

have 'mucked' and 'bohunked,' working in this camp can only be expressed by the ancient phrase *damnati ad metalla*.

It may not be necessary "for an engineer to have thumped a drill or shoved a car in order to detect whether the one kind of work or the other is being done properly," but I doubt if an engineer can gain a true understanding of the effect that good or bad treatment and living conditions have on a man's attitude toward his work, unless he has worked under favorable and unfavorable conditions himself.

CURT N. SCHUETTE.

Somewhere in the West, June 26.

Uraninite in Colorado

The Editor:

Sir—In response to your request for information concerning my discovery of pitchblende in Gilpin county, 45 years ago, I send you a copy of a short paper of mine which appeared in the Proceedings of the Colorado Scientific Society (Vol. V, page 156), which gives the true story of my discovery of uraninite in Gilpin county, Colorado, in 1871, as described by me in 1895.

The clipping from the Montana paper, you will see, is incorrect. The discovery was made in the Wood lode, and a lease for working was obtained some two years before I became associated with Prof. Hill at Black Hawk.

It may be of interest to record a peculiar feature connected with the deposit of mixed minerals, pyrite and chalcopyrite. My paper was written long before the discovery of radium or the radio-active properties of pitchblende. In the concentration of the mineral for the separation of the pyritic minerals associated with the pitchblende, I noticed that the copper pyrite was blackened on the surface; it had the appearance of being 'powder-smoked.' The black stain, however, was only skin-deep, for a fresh fracture showed the brilliant yellow characteristic of copper pyrite. I was at a loss to account for this strange appearance at the time, but when the wonderful radio-active properties became known, I had no hesitation in assuming that the black deposit was due to radio-active forces.

From the fact of there being such a large deposit of pitchblende covering a comparatively small area, the adjoining rocks would, in all probability show, on examination, indications of the alteration of uranium with its ultimate product helium. It has occurred to me that samples might be taken by sinking into the rock, some distance below the surface, or better still, by driving a small cross-cut into the country-rock each side, north and south. These samples need not be large; blocks about one pound in weight would be quite sufficient, being carefully labeled and making the distance from the deposit.

Professors Joly, Rutherford, and Strutt, who have given a great deal of attention to the subject, might be glad of the opportunity of investigating a matter of such great interest at this time.

It is difficult to arrive at even an approximate figure as to the quantity of pitchblende already extracted from the Wood lode. My own figures, which cover the amount extracted under my lease in the year 1872, would represent, in round numbers, three tons of 60% U_3O_8 . Later, in 1904, I purchased some ore from other lessees, which would perhaps represent altogether two tons more. Since the shaft, in which the discovery was made, was sunk clear through the thickest part of the vertical lens-shaped deposit, the quantity of material sent to the stamp-mills and smelting-works at Black Hawk to determine its value could not have been much less than another three tons of 60% stuff. What has been done since, I do not know, but if we add still another two tons for later discoveries, we have a total to date of, say, 10 tons of concentrated material of about 60% U_3O_8 .

The presence of such a large quantity of pitchblende must have had great influence on the adjoining rocks, and one might expect to find strong indications of helium as a result of radio-activity produced on a large scale.

RICHARD PEARCE.

Liverpool, May 28.

The Occurrence of Uraninite in Colorado

By Richard Pearce

*This rare and interesting mineral was first discovered in Colorado by me in August, 1871, and occurred in what is called the Wood lode in Leavenworth gulch, Gilpin county, about one and one-half miles from Central City, and not at Black Hawk, the locality given in Dana's 'System of Mineralogy.' As the discovery was made nearly 21 years ago, it may prove of interest to the members of this society to have recorded a few details regarding its discovery, and the peculiar conditions under which it was found.

In the summer of 1871 my attention was directed to a group of mines in Leavenworth gulch, owned by the Rochdale Mining Co., and in the course of my examination of one of the several claims belonging to this company, I found on the dump of the Wood claim a heavy black mineral which proved to be uraninite coated with a beautiful canary-yellow material, uranium vitriol, a basic sulphate of uranium formed from the oxide by lengthened exposure on the surface.

The mine had been worked for gold some years previous to 1871, and a considerable quantity of ore was mined and sent to the mill, and, it is believed, to the smelter, but the results were not satisfactory, and the mine was abandoned. The agent of the company stated that the mill men objected to the ore on account of its high specific gravity, as it hung most tenaciously to the

plates and scoured the amalgam; he also stated that a load of the ore was sent to the smelter to be tested, and, after sampling and assaying, it was found to contain no gold, pronounced worthless, and thrown into the creek.

The discovery of uraninite thrown broadcast, on an old dump, was a source of astonishment to me, for I had been accustomed to see it only in very small quantities, and under peculiar geological conditions. At first I could hardly venture to trust my own opinion; and a blowpipe apparatus, the property of an old Freiberg friend, being found at one of the mills close-by, in Russell gulch, a quick test proved the existence of uraninite, or 'pitchblende,' as it was commonly called.

About 200 pounds weight of the mineral was sorted out of the dump and sent to me, at Swansea (Colorado). There it was still further selected and sold to the firm of Johnson & Matthey, London, for the sum of £42, or \$210.

The rock in which the Wood lode occurs is mica-schist traversed by veins of feldspar and quartz enclosing magnetite, and the lode, which had been explored only to the depth of about 60 ft., was said to be four feet in width with six inches of solid uraninite. The associated minerals, as seen on the surface, were pyrite, chalcopyrite, with small quantities of pyrrhotite and galenite, the gangue being mainly quartz.

A lease of the property was obtained in the following year, and the mine was re-opened and worked for uranium. It was found that the shaft had been sunk through the centre of a vertical lenticular deposit of uraninite, and, consequently, the richest and by far the largest bulk of the ore had been lost through ignorance of its value. That portion, however, which was left, was extracted, and, after careful sorting, about 3 tons of rich ore, containing about 60% of pure black oxide of uranium, was shipped to London where it realized about \$7500.

History repeats itself. In 1894, twenty-three years later, the mine was again opened and worked on lease, and in driving west from the old shaft at a greater depth, another lenticular deposit of uraninite was encountered; but as the nature of the mineral was unknown to the people who had the lease, the same disappointment from the mill-returns was experienced as in the first discovery. A specimen of the ore was brought to me by the lessee, who had heard from some source that I had found something rare and valuable in the Wood lode many years before. The new find proved to be uraninite of exactly similar character as the first deposit found in 1871. I purchased a quantity of the ore, but have not as yet been able to find a satisfactory market for it.

The mineral uraninite formed the subject of some highly interesting investigations by a former president of this society, Dr. W. F. Hillebrand, who pointed out, for the first time, that it contained the element nitrogen. More recently Prof. Ramsey has discovered that the large bulk of the gas thought to be nitrogen by Dr. Hillebrand, proves to be the new element helium.

The Motor-Truck in Arizona

By Wilbert G. McBride

TWO Alco 3½-ton motor-trucks were used by Young Bros. while operating at the Mammoth Collins mine at Shultz, Arizona. One was equipped with an oil-tank holding 1075 gal. and was used for the transportation of 'tops.' The other was fitted with a stake body and used to carry machinery, wood, rails, pipe, and all classes of miscellaneous supplies. The bodies were made of oak with maple flooring and were attached to the frame of the chassis by U-bolts, to avoid drilling the main members of the frame.

Most of the hauling was done from Tucson, a distance of 47½ miles. During the first three months, part of the road was in bad condition and the tire cost was excessive. After this part was repaired, the road was in fair condition, but never good. There were no excessive grades or bad sand, but wagon-ruts, too narrow for the truck-wheels and of a different gage, caused heavy tire loss; while chuck-holes, sharp curves, and stones, both imbedded and loose, were objectionable features. During wet weather the trucks could not get sufficient traction to climb some of the hills and were likely to stick in the mud, so that no attempt was made to run them unless they were on the road when the rain started. This lost time amounted to about 5% of the total, but, whenever possible, it was utilized in making minor repairs.

The price of gasoline was from 17 to 21c. per gal. Rubber tires were used throughout. Drivers were paid \$4.50 to \$5 per shift, and a return trip to Tucson was counted as two shifts even when made in one day. Drivers were provided with a room in Tucson and were paid for all time lost due to causes beyond their control. Trucks were loaded one way only.

Speedometers were placed on both trucks, but the excessive vibration soon caused them to fail. For this reason, and because no account was taken of the distance covered in picking up a miscellaneous load or in other minor ways, the mileage given is under the actual distance traveled. Some of the weights had to be estimated, but care was taken to have the number of ton-miles low rather than high, to avoid under-estimating the costs. The cost of hauling from Tucson to the mines was \$12 per ton with the trucks, while the best possible team price was \$15. Teams made one return trip a week, while the truck regularly made one in two days and could always, and many times did, do it in one day. The loss of time due to wet weather would be about half as much with teams as with trucks.

The table of detailed costs given below covered the period from August 21, 1913, to August 15, 1914, the

only time in which the trucks were continuously employed. From August 15, 1914, to March 30, 1916, the trucks were used intermittently, but the figures for this period have been excluded as not being representative. If included, they would lower the cost per ton-mile. Just prior to the close of the period covered by the figures, the trucks were overhauled and put in good condition; new rear-wheels were put on and new tires substituted. The cost of all this was charged to operation. Allowances for extra tires on hand would reduce the cost per ton-mile approximately 3c., leaving a net cost of about 25c. With loads on the return-trip this cost per ton-mile would be lowered at least 40%.

OPERATING DATA

Total distance traveled by trucks	23,000 miles
Total work done by trucks	42,700 ton-miles
Average distance covered per gallon of gasoline	4.5 miles
Average distance covered per gallon of lubricating oil	128 miles
Average speed, loaded	7 miles per hour
Average speed, light	7.8 miles per hour

DETAILS OF COST

	Total cost	Per cent of total	Per truck-mile	Per ton-mile
Wages of drivers	\$2,623.32	23.91	\$0.1141	\$0.0614
Wages of helpers	286.50	2.62	0.0125	0.0067
Repairs, labor	581.74	5.30	0.0253	0.0136
Repairs, lost time	156.15	1.42	0.0068	0.0037
Oils, grease, and waste	379.17	3.46	0.0165	0.0089
Gasoline	1,619.49	14.68	0.0700	0.0377
Tires	2,415.75	22.30	0.1063	0.0573
New parts	515.08	4.69	0.0224	0.0121
Miscellaneous supplies	348.82	3.18	0.0152	0.0082
Incidental expense	226.21	2.06	0.0098	0.0053
Depreciation	1,796.80	16.38	0.0781	0.0421
Total	\$10,970.03	100.00	\$0.4770	\$0.2570

The advantage of the motor-truck over the team and wagon are many—increased speed, ability to work 24 hours per day when necessary, and lower cost on long hauls—but its adoption by the mining industry has been slow. Where trucks are used around mines they are usually driven by cheap inexperienced men, the upkeep and repairs being turned over to the regular mine mechanics. It would be equally good practice to employ a timber-framer to make a dining-room table. Just as the niceties of cabinet-making are unknown to the timber framer, the exact adjustments and fine workmanship of the high-speed engine and transmission-gears of a motor-truck are beyond the ken of the mine mechanic, one of the least skilled of his class. If there are enough motor-vehicles at the mine, the master mechanic probably turns the work over to one or two men who, in time, become in-

*A paper to be read before the Arizona (September 1916) meeting of the American Institute of Mining Engineers.

different auto-mechanics, but in the meantime the cost of maintenance soars and often the trucks are condemned. The aim of the makers of all motor-vehicles is to secure the maximum of strength and power with a minimum of weight and size. To do this, high-speed engines, the best of materials, and the finest of workmanship are employed, and parts are reduced to the least possible weight consistent with strength and durability. This is just the reverse of the ordinary American mechanical practice, in which reliability is secured by slow speed and large size, the amount of material used and the space occupied being minor considerations. It is, therefore, unreasonable to expect the mechanic trained in one school to understand immediately and adapt himself to the ways of the other. It must also be remembered that no other machine is given the hard use and necessary abuse that motor-trucks receive. The vibration while on the road will loosen nuts and rivets, and this, if not attended to in time, will cause serious trouble. Where only one or two trucks are used, the drivers should be competent mechanics and should be held responsible for the maintenance of their machines. Where several are used, they should be under the direct supervision of a thorough truck-mechanic that is held responsible for operation and given entire control of the drivers and repair-work. His constant care will detect and remedy many incipient defects and prevent expensive and annoying break-downs. With the exception of the time required for periodic overhauling, he should be able to keep the trucks in almost continuous service. This will make possible the employment of cheaper drivers without undue damage to the machines.

Motor-trucks should not be installed without careful consideration of the roads to be traveled. The difference between the cost of motor-truck and team-hauling is largely controlled by the quality of the road, and on really bad roads the motor-truck is decidedly the more expensive. Many roads are fatal to truck-haulage, and considerable experience is required to decide this question without an actual test of some duration. Excessive grades are to be avoided, especially long ones. The ordinary truck will pull over a short 20% grade with ease, but will give great trouble on a long one of half that rise unless special cooling arrangements are made. Grades greatly increase the tire and gasoline consumption and decrease the life of the machine. Rocky roads, particularly when the rocks are sharp or loose, are hard on tires. Deep sand is difficult to cross, and for this class of road the caterpillar tractor and the four-wheel-drive truck have distinct advantages. Trucks that drive on the rear wheels only cannot operate in heavy sand. Narrow or rutted roads are objectionable for the larger-sized trucks because they throw all the weight on one of the rear dual tires from time to time, and this over-loading is injurious to the rubber. Fairly deep streams can be crossed, but mud is an absolute barrier except to the caterpillar type of tractor. Few dirt-roads will stand up under a 7-ton truck, but those of 4 tons, or under, do less damage than the ordinary freight-wagon.

Unfortunately, trucks are not designed to suit mining conditions. At Shultz we found it necessary to cut down the gear ratio, increase the size of the wheels and tires, and add bumper or auxiliary springs. Had the grades been steeper it would have been necessary to increase the cooling capacity.

For long hauls the motor-tractor will probably replace the motor-truck. It will operate at a lower cost because the load will be carried on iron tires, and, as the table of detailed cost shows, the rubber tires account for 22.3% of the total. Tractors travel more slowly than motor-trucks, but the tonnage hauled on a trip is much greater. They are also easier on roads, as the load is distributed over several trailers. By using extra trailers, loading and unloading can be done on the road.

The make of a truck is not as important as the care it receives. Almost any standard make will do good work if given careful attention, but none will be satisfactory if not well cared for. Economy should not be sought in the lubricants used; the best oil is none too good. Overloading should be scrupulously avoided. A truck may be made to carry many times its rated load without breaking down, but the damage is none the less real because not immediately apparent. High speed, particularly if the road is rough, should be avoided, since it subjects the machine to excessive strain and vibration. Most trucks are now equipped with speed-governors, but these are easily tampered with and must be carefully watched. When they are not used, the drivers should be carefully instructed as to the speed-limits and compelled to respect them.

Distillate and 'tops' are now successfully used on trucks, by the application of a special carburetor. The use of these should effect a material saving in the gasoline cost, which now amounts to almost 15% of the total. 'Tops' usually sells for 30 to 35% and distillate for 50 to 60% of the price of gasoline. With a properly designed carburetor, the available power in the lower-grade fuel will be about the same as in the gasoline, but the carbon deposition will probably be somewhat greater.

SHOVELING of broken rock underground in the lead mines of south-eastern Missouri averages 18 tons per man per shift. The shovels used are long-handled round-pointed No. 2 type, requiring about 130 shovelfuls to fill a ton car, or a load of 15 lb. per shovel. The cost of shoveling averages 13c. per ton. Short D-handled shovels, such as are used in the mines of the Lake Superior region, are not liked in the lead mines. The advocates of the short shovel claim that a man can make more and faster motions with the shorter tool than with the long-handled shovel, and can turn around more quickly in a narrow drift. But, it is argued in answer to this, the amount of rock that a man will shovel in a day is not measured by the fast motions that he can make while the boss is looking, but by the continued strain on his back. The long-handled shovel scatters the muscular effort over the body, taking some of the burden from the back and placing it on the legs.

The Flotation of Minerals

By Robert J. Anderson

*Many phenomena are supposed to contribute to the flotation of minerals, whether in whole or in part is a mooted question. I shall only sketch roughly the present tendency of ideas and make no reference to the first early and crude notions, which are now mainly of historical interest.

SURFACE TENSION has been well defined in articles appearing in the *Journal of the American Chemical Society* during the years from 1908 to 1913. The theory has been treated in particular by Laplace, Gaus, and more recently by Van der Waals, and by Willows and Hatschek.¹ As defined by Jones,² "potential energy, present at the surface of liquids, produces a tension which is known as surface tension." The phenomena invariably indicative of surface tension are: Drops of a liquid not exposed to an external force, that is, either suspended in another liquid of the same specific gravity or freely falling, assume a spherical shape, the sphere being that form of body with the smallest surface per given volume; further, if water be placed in an open vessel its surface film will be a measurable quantity, and its thickness will vary with a number of factors of which temperature is one. Its thickness is observed as ranging from 4×10^{-5} cm. to 4×10^{-6} cm., and its density, when referred to the main bulk of the water below, will approximate 2.14. Surface tension is not affected by the surface area. It is numerical in value and expressed in dynes per centimetre. It is a variable factor dependent on temperature, increasing numerically with falling temperature, for example, water at 18° C. has a surface tension of 73 dynes per centimetre, and at 0° C. this increases to 75 dynes. At the critical temperature of a liquid its surface tension becomes nil.

All liquids have a definite cohesion or tensile strength, which is ascribed to the mutual attraction of their molecules. This then is comparable to a pressure existing within a liquid, which has been termed the 'intrinsic' pressure. Naturally the value of the surface tension of solids is numerically high. The surface tension of a pure liquid against its vapor is markedly affected by the addition of soluble contaminants. Some salts will raise the surface tension of water while others will lower it; the fact that the salts of weak acids will lower the surface tension of water is explained by the fact that free acid is liberated by hydrolysis. It is further known that all acids will lower the surface tension of water, which is

also decreased by the addition of oil, or, in other words, oil will reduce the interfacial tension between the water-air phases. A phenomenon for which no explanation has been given is the one showing that the addition of contaminants may either raise or lower the surface tension of water, but such addition, while it may decrease that tension greatly, can increase it only slightly. Any lowering of surface tension is more marked in a liquid that has a high surface tension, such as water, than in liquids of low surface tension.

There can be, of course, no surface tension without adsorption, which produces, in the case of positive adsorption, an increased surface concentration resulting from a lowering of the surface tension by the contaminating and dissolved substance, whatever it may be. The equation of Gibbs ($u = -c/Rt \cdot d\sigma/dc$) gives the relationship between surface tension and the distribution of the solute between the bulk of the liquid and the film interface. Here the notation is:

u = excess of substance in the surface layer,

c = concentration in the main body of the liquid,

R = the gas constant,

t = absolute temperature,

σ = surface tension.

This shows that when the surface tension is reduced by the addition of a contaminant, the quantity du/dc is negative and u is positive (from algebraic consideration). The surface film then contains more of the contaminant than the main body of the solution. If the surface film contains less of the contaminant than the main body of the solution it is a case of negative adsorption.

As given in the foregoing, the surface of a liquid against its vapor is in tension; the surface of liquid against another liquid, or a gas or solid, is also in a state of tension; this is termed 'interfacial.' In the flotation machine the following conditions obtain: Pulp consisting of ore of approximately 80-mesh, water in ratio of 3:1 of ore, and oil in disappearingly small amount, is being violently agitated. For the sake of a specific case, the air is being forced mechanically into the swirling pulp by beaters or stirrers. The phases present in flotation by the oil-froth process are therefore: solid-liquid (ore-water), solid-liquid (ore-oil), solid-gas (ore-air), liquid-liquid (water-oil), liquid-gas (water-air), and liquid-gas (oil-air). Thus six tensions are present, but if the oil is soluble in the water the tensions are reduced to three. It is known that pure water cannot be made to maintain a persistent froth because its surface tension is too high. Acid, if present, will lower the surface tension of water, as will oil, if it is soluble.

Certain metallic sulphides, such as galena, have the

*Abstract of paper to be read at the forthcoming Arizona (September 1916) meeting of the American Institute of Mining Engineers.

¹Willows and Hatschek: 'Surface Tension and Surface Energy,' 1915.

²Jones: 'Elements of Physical Chemistry,' 1907.

power of floating on undisturbed water; they are not wetted and the curve of contact is convex. Some gangue minerals, such as quartz, possess an adhesive force of attraction for water that exceeds the intrinsic pressure of the water; they are therefore wetted and sink to the bottom, being drawn through the surface film. Such properties of the minerals are affected by the presence of oil, acid, and other reagents. Oil has a greater adhesive attraction for sulphide minerals than for gangue minerals; and the addition of acid and oil (if it is soluble) acts as a contaminant that will lower the surface tension of the water and aid in the production of a persistent froth. Let us now look into the question of adsorption and see what part it plays in flotation, since it is so requisite to the production of a variable surface tension.

Adsorption. Generally speaking, adsorption deals with the unequal distribution of substances at the interface between dissimilar phases such as, solid-solid, solid-liquid, solid-gas, liquid-liquid, liquid-gas, and gas-gas. It is purely a physical effect. Commonly, adsorption⁵ is construed to be the result of the condensation of a disperse phase upon the interfacial boundary solid-liquid. Returning for a moment to the Gibbs equation quoted above, adsorption may occur if the interfacial tension solid-liquid is reduced, this being positive adsorption. If, however, such an interfacial tension is raised in value it is a case of negative adsorption, as the solute or disperse phase will be rejected from the surface. Any condensation, strictly stated, of a solute or disperse phase in the interfacial boundary separating liquid-liquid or liquid-vapor is held to be a special case of adsorption. However, in the general sense, the phenomenon is looked upon as being the result of condensation of a disperse phase in the interface of two immiscible phases. Adsorption is shown strikingly by colloid gels—the product obtained by the coagulation of sols—and certain cases of selective adsorption are most remarkable. Adsorption will naturally vary with the surface exposed. In Miss Benson's experiments with amyl alcohol in aqueous solution, amyl alcohol reduced the surface tension of the water, and it was found by producing a voluminous froth that the alcoholic concentration in the froth exceeded that in the bulk of the aqueous solution by about 5%. A froth has a very large surface, and it would be expected that the adsorption would be greater. Such experiments prove the value, qualitatively, of the Gibbs rule.

Recent work shows that all solids do condense gases on their surfaces and retain them there with great tenacity. Liquids in like manner adsorb gases. Further, liquids and solids exhibit selective adsorption of gases. Although this selective adsorption obtains, no proof has been submitted indicating that the amount of gas adsorbed by one substance is largely different than the amount adsorbed by another substance. An electric charge on an adsorbed substance probably would influence the amount adsorbed. The adsorption of air

plays an important role in flotation, for as Breuer points out, the adsorbed air film is enormously responsible in preventing the coalescence of solid particles.

A comprehensive study of the adhesion of small particles of solid to the dineric interface (surface separating two liquid phases) has been made by Hofmann⁴ based on the theory of Des Coudres.³ From the standpoint of flotation this may be given as follows: If a solid particle, such as quartz, is wetted much more strongly by water than by another liquid, such as oil, the water will displace the oil, and a film of water will form about the quartz particle according to the relative forces of adhesion. Then the quartz particles will remain in the water phase if the water has a specific gravity greater than the oil, regardless of their size; but if now the oil has a greater specific gravity than the water, then the quartz particles will remain in the water phase until the size of the particles is such that the force of gravity will remove them from the water. Conversely, if a solid particle, such as galena, is wetted more strongly by oil than by water, the oil will form a surface film about the particle and hence prohibit the particle from being wetted by water, that is, from entering the water phase. Then the galena will only enter the water phase when the water is more dense than the oil, and, further, when the galena particles are of such a size that the force of gravity overcomes the adhesion of the oil film to the oil.

Returning to purely theoretical considerations, Hofmann draws certain conclusions that deal with the supposition that solid particles will then remain in the surface separating two immiscible liquids, if these particles are wetted partly by each liquid. I quote Bancroft at length on this matter.⁶ "The solid particles tend to go into the water phase if they adsorb water to the practical exclusion of the other liquid; they tend to go into the other liquid phase if they tend to adsorb the other liquid to the practical exclusion of the water; while the particles tend to go into the dineric interface in case the adsorption of the two liquids is sufficiently intense to increase the miscibility of the two liquids very considerably at the surface between solid and liquid."

Any simultaneous adsorption of two immiscible liquids by a solid would tend to form a homogenous liquid phase at the surface of the solid.

In regard to the effect of contaminants or other impurities in contact with two immiscible liquids, this condition obtains: If the contaminant is soluble in one liquid but not in the other, and also lowers the interfacial tension of the two, the equation set forth by Gibbs exacts the requirement that the contaminant should obtain in the interface. Examples of this prove the validity of the law.

The terms adsorption and absorption have been used interchangeably in some writings, thus contributing to the already existing confusion of ideas.

Absorption or Occlusion. There are three ways by which gases can be held with reference to solids: (1) By surface adsorption; (2) in solid solution; and, (3) by occlusion. The term 'occlusion' has been applied indiscriminately to any of these methods by which gases are held by solids. Strictly speaking, by 'occluded' gas is meant gas that is absorbed and held in finely-divided pores or openings, which may be of microscopic size. A recent theory¹ holds that occlusion plays the operative role in the flotation of minerals by all processes. I am unable to reconcile myself to this explanation, for a number of reasons. Marked instances of occlusion at normal temperature are known only in certain amorphous substances, like charcoal. Many metals, of course, both in the liquid and solid states, have the power of occluding gases, often in marked degree. There may be and undoubtedly are fine pores in the floatable minerals, which may in a sense be considered as an assemblage of capillary tubes; these can and do occlude gas. Yet occlusion is marked only in amorphous substances and in certain metals as just stated. It is definitely known that occluded gases are retained with great tenacity by the substances occluding them and therefore are expelled only with difficulty. It seems anomalous to hold that the occluded gas can depart from the mineral occluding it with sufficient speed to aid the air bubbles in the liquid in the process of flotation. I believe firmly that occlusion is not a cogent factor in flotation, and that a more consistent theory may be formulated without postulating these conjectures regarding occlusion.

Colloids. In the original definition of the term by Thomas Graham, do not constitute a definite class of substances; a large number of different substances may be made to assume the colloidal state if proper precautions are taken. All of which reveals the striking fact that this colloidal condition is a *state* and not a *form* of matter. The ultra-microscope of R. Zsigmondy and H. Siedentopf has greatly increased our knowledge of colloids. A general statement may be made regarding colloids; that they do not show osmotic pressure in appreciable amount. Colloidal solutions—sols—are regarded as systems of two phases, in which the dissolved substance is the disperse phase and the solvent the continuous phase.

Since, in flotation, the ore is often as small in size as certain of the colloids, the pulp (ore, water, etc.) can be looked upon as a coarse suspension, and the laws of colloids apply here with equal force as in the realm of colloidal chemistry. So-called suspensions are systems consisting of solid particles of microscopic size distributed through a liquid. As mentioned by Ralston, Reinders has treated at length the particular case of a solid phase maintained in contact with two liquid phases, that is, two immiscible liquids. His work is based on the different

interfacial tensions existing, and his experiments and those of Hofmann, as mentioned in an earlier paragraph, have considerable bearing on the flotation problem.

Emulsions are fairly coarse dispersions of one liquid in another with which it is immiscible. The simplest and commonest emulsions are the pure oil-water emulsions, containing no emulsifying agent such as soap, proteins, etc. In such systems the oil globules can be coagulated by electrolytes, they show the Brownian movement strikingly, and can even be retained by some filtering media. Any process of emulsification is dependent on a lowering of surface tension, or, to be more precise, on a lowering of the interfacial tension between the two phases. According to Briggs and Schmidt, the two essential requirements of an emulsifying agent are: (1) The property of condensing by adsorption in the dineric interface; and (2) the ability to form under these circumstances a strong coherent film. Temperature is a decisive factor in emulsification, for its effect is to reduce the interfacial tension between phases and also to lower the viscosity of the phases. In the production of emulsions, a considerable amount of surface energy is produced because of the relatively large surface area of the disperse phase; an emulsion is the more speedily effected if such surface energy be reduced by the use of a liquid having a low surface tension as the continuous phase. Some emulsions, under certain conditions, display a great increase in viscosity over that of either of the immiscible phases, for example, the emulsions of the Pickering order—up to 99% of oil in 1% of soap solution—can be cut into cubes. Any emulsion produced with soap solution is at once destroyed by the addition of acid, as the latter will decompose the soap.

If solid particles are suspended in a liquid, they tend to increase the viscosity of that liquid gradually, depending on the amount of solid particles present. Experiments have shown that whenever a substance in suspension is wetted by two immiscible liquids simultaneously, it will go into the dineric interface in the manner already mentioned, and will tend therefore to produce an emulsion. If, however, the suspended particles cannot coalesce, owing to adsorbed oil film or for other reasons, and thus effect the production of a coherent film, the emulsion will not be stable. Few data are available on the production of emulsions by the oils used in flotation work, or on the matter of interfacial tensions between such oils and water. However, we are now dealing with emulsified or partly emulsified pulp in some of the flotation processes, in the oil-froth process at least.

ELECTROLYTIC AND ELECTRO-STATIC PHENOMENA. Any substance placed in contact with water or any other liquids will assume an electric charge, the sign of which is, as yet, not set forth. Most substances when in contact with water become negatively charged, but these charges can be differed at will or reversed by the addition of the proper electrolyte in requisite amount. These electric charges are by no means confined to substances

¹Durell: M. & S. P., Vol. CXI, No. 12, p. 428 (Sept. 18, 1915) and Durell: *Metallurgical and Chemical Engineering*, Vol. XIV, No. 5, p. 251 (March 1, 1916).

²Ralston: M. & S. P., Vol. CXI, No. 17, p. 624 (Oct. 22, 1915).

³Briggs and Schmidt: *Journal of Physical Chemistry*, Vol. XIX, No. 6, p. 479 (June 1915).

scopic particles, but are found also on the particles of a coarse suspension. Gangue minerals, such as quartz, when suspended in water, are negatively charged, and sulphide minerals, such as pyrite, are positively charged under like conditions. Oil drops are negatively charged, as are air bubbles under certain conditions. These charges are very minute when referred to the mass of the particle. Substantial evidence is at hand to show that floatable minerals have the positive sign of electricity when suspended in water or can be made to assume that sign by the addition of proper electrolytes in sufficient amount. As Callow¹⁰ observes, there is a parallelism between electro-static characteristics and the floatative properties of ores. Many of the electro-static principles have either been carried too far or misapplied, as recent work shows.

Experiments in colloid chemistry indicate that the contact films are charged and that such charges affect the dispersion or coherence of the particles in suspension. Of course, oppositely charged contact films will coalesce while similarly charged contact-films will repel each other, if the charges are sufficient in amount to overcome the force of cohesiveness; in the latter, dispersion is the result. The oil and air contact-films having negative charges would tend to attract the sulphide particles, but further than this possibility electro-statics probably plays little part in flotation.

It is generally admitted that only good conductors are suitable to flotation. Now then, as the electrical theory contends, electrified bubbles must be supplied to float the conducting minerals that are attracted, leaving behind those that are not. The bubbles in flotation are simply air spaces contained by a mantle of oil or of water, and there is, therefore, nothing within to bear the charge. In case it could carry a charge, which would only be possible by the presence of contained ionized gases or water-vapor, the charge would be speedily dissipated by contact with the interfacial boundary. Then in order that a bubble may carry a charge it must be protected by a dielectric film. Further, electro-statics plays probably little part in holding the sulphide particles and the gas bubbles together, as neither the bubble nor the particle can have a charge of sufficient magnitude when referred to the size. The electrical theory has been strongly championed by at least one writer¹¹ and has been tolerated by some others. A recent article¹² indicates that the principles of electro-statics have been considerably misapplied. It is my belief that electro-statics may be a small contributing factor in flotation in a manner not as yet understood because of a lack of information concerning charges at the interfacial boundary between immiscible phases, for ex-

ample, where the colloidal state is introduced in oil-water emulsions. Apparently, the electric theory is not important.

FROTH AND BUBBLES. The idea has been abandoned by most people that a low surface tension is the essential requirement for froth formation. As mentioned by Coghill in a recent writing,¹³ the contamination of the liquid with an impurity that will cause a variable surface tension is the real requirement. A bubble of air is spherical in shape and this shape can only be maintained if the external pressure exceeds the internal pressure. Since a bubble does not expand *per se*, large bubbles can only be accounted for by heat, coalescence, or electrification. Viscosity is an important factor in froth-persistence, as it increases the tenacity of the liquid film and thus prevents ready rupture. The rupture or bursting of bubbles is explained thus:

1. Concussion upon a surface film deficient in the requisite viscosity and variable surface tension.
2. Relief of pressure—here the gas of the bubble in expanding exerts a pressure exceeding that of the liquid film.
3. Adhesive force of the entrained gas for the atmospheric air.
4. Evaporation of the liquid film.

Flotation bubbles will burst for any one or a combination of these reasons.

Solutions in which the continuous phase is a solution of soap, various products from the saponification of albumens, etc., will froth voluminously even in a very diluted condition; frothing never occurs in pure liquids and is a definite proof that the solute or disperse phase lowers the surface tension of the solvent. A froth, which shows adsorption at the interfacial boundary of solution and gas, depends for its persistence on the production of a viscous film at that boundary; these viscous films are the direct result of surface adsorption of the disperse phase, that is, dissolved contaminants, the amount of which is small—disappearingly so. The work of Hall and of Miss Benson shows that in a foaming liquid the foam is richer in the dissolved contaminant than is the bulk of the liquid. Froth formation in the Callow cell is the result of the injection of air into the pulp (already emulsified); the froth persists as long as there is sufficient air injected into pulp of the proper consistence. The froth in the Callow cell is governed in nature by the kind of oil used and by the amount of air. A pneumatic froth is unstable or ephemeral; it dies when removed rapidly from the influence of the injected air. The mechanical froth, on the other hand, is thick and persistent, and must be broken up in dewatering the concentrates.

Oils have a selective action for metallic sulphides, tellurides, and some other minerals. The fact that both the oil and the air or other gas have a selective adhesion for sulphides prevents them from being wetted by water. Conversely, the quartz and other minerals exhibit just the opposite characteristics. The gangue-minerals, generally, do not exhibit adhesion for either gas or oil:

¹³ "The Science of a Froth," M. & S. P., February 26, 1916.

hence they are readily wetted by water. Gases have a well-defined adhesiveness for oils; therefore the air or gas adheres strongly to the oil film. The stability of a froth depends, in the main, on the kind of oil used, for example, pine-oil makes a weak brittle froth, and creosote makes a stable elastic froth. The work of Devaux¹⁵ on oil films explains how so small an amount of oil as is used in the various flotation processes can be so efficacious. From a consideration of the immiscible oil-water interface, if any oil will film the internal surface of a gas bubble the sulphide particles would be contained in the oil-water interface no matter what the nature of the gas contained by the water film. The sulphide, if it enters the oil phase, would then present an oiled surface to the water phase. There are three conditions then: (1) The mineral enters the oil phase completely; or (2) the mineral enters the water phase completely; or (3) the mineral enters the oil-water interface.

Experiments made to determine the nature of the frothing selective, and collective action of different oils show some interesting results. I made tests on a zinciferous slime from Joplin with different oils, the results obtained indicating that a definite mixture of oils will effect better recoveries than any one oil alone. The best combination consisted of pine-oil as a frother, plus wood-creosote as a frother and selector, plus refined tar-oil as a froth stiffener.

In general, pine-oil makes a brittle froth, which immediately dies; creosotes make a more elastic froth, the bubbles of which may expand to 3 in. diam. or more before rupture. Coal-tar products are poor frothing agents and if used must be aided by either creosote or pine oil to produce a good froth. Oils of a lubricating nature seem to be of little value in flotation, while such light oils as gasoline and naphtha are of value only for thinning the heavy coal and wood tars.

AIR AND GAS. At this time, there are three ways by which a gas may be forced into a solution mechanically as follows:

1. By beating it into the solution by means of paddles, as in the Minerals Separation and similarly mechanically agitated machines.
2. By pneumatic means, as in the Callow cell, where the air is divided by the porous blanket-bottom into minute sprays.
3. By so-called liquid jets, as in a process recently patented in which the air is introduced as a surface film surrounding a liquid jet by surface tension.

Conversely, there are three methods by which dissolved gas may be expelled from a liquid:

1. When the liquid is super-saturated, the excess gas is expelled.
2. By heating the liquid, when some of the gas is expelled owing to an increase in its volume.
3. By pressure reduction, as in the Elmore vacuum process, where, according to the law of Henry,¹⁶ "the

amount of gas dissolved by a liquid is proportional to the pressure to which the gas is subjected."

An air or gas bubble on being introduced into a liquid is at once surrounded by a film of the liquid. Such a bubble will rise to the surface (carrying the metallic sulphides by reason of the forces already mentioned) on account of gravitation, by which is meant that the adherence of the air to the liquid is less than the force of gravity.

RÉSUMÉ. From a consideration of the foregoing, it is believed that the theory based on the different interfacial tensions involved is the dominating one at this time. Probably flotation is due to a combination of complex phenomena. The theory based solely on occlusion goes "by the board," as has been shown that the contributing effect of this phenomenon has been interpreted laxly.¹⁶ The phenomenon of electro-statics may be a small contributing factor, but recent work indicates that the principles have been misapplied. An explanation more in consonance with fact can be given in terms of the interfacial tensions involved, without postulating either occlusion or electro-statics.

The main and essential requirements for froth flotation are: (1) The production of a persistent froth; (2) the attachment of the bubbles of air to the sulphides or other material to be floated; and (3) the maintaining of a selective action by the froth bubbles for the sulphides or other material to be floated.

REDWOOD is the famous big tree of California. Its property of resisting the action of acid and alkaline solutions, oils, insects, and decay in general, has brought it to the attention of miners and mill-men. Nearly 40% of the lumber cut annually in California is redwood; in 1915 redwood furnished 418,824,000 ft. of a total of 1,118,703,000 ft. cut. It belongs to the genus of conifer (or cone-bearer) called *sequoia*, which forms one of the links between the firs and the cypresses. Two species are found in California, the *sequoia sempervirens* of the Coast Ranges, and the *sequoia gigantea* of the Sierra Nevada, the largest of known conifer. The *sempervirens* is the typical redwood of the California woodsmen. It grows to large size, up to 12 ft. diameter and 270 ft. long. The boughs are few and short, and the trunk is straight. The wood is like cedar, it splits evenly, and polishes well. While strong and durable, it is not especially elastic. The tree does not grow in other parts of the United States. The species *sequoia gigantea* is confined to detached localities in the Sierra Nevada, usually at an elevation of 4000 or 5000 ft. A few have attained a height of 400 ft., some are believed to be 3000 years old. They are the remnants of extensive forests belonging to a past epoch. Nowhere else in the world are red woods of large size found.

COPPER production of Russia during 1915 was 29,800 short tons, compared with 36,430 tons in 1914.

An Earthquake in Nevada

By E. L. Berry

The old mining town of Kennedy, in Humboldt county, is situated in the East Humboldt range, in township 28 north, range 38 east, and is about half-way up the eastern side of the range above Pleasant valley.

On October 2, 1915, at 3:40 p.m. there occurred an earthquake shock of sufficient intensity to be felt plainly by persons standing on the ground. This was followed by light ones until about six o'clock, when a fairly heavy one was noticed, followed by light ones at frequent intervals. Conditions were such that it was thought advisable to place crockery on the floor. About nine o'clock things quieted down to such an extent that it seemed safe to retire for the night.

At about 10:50 there was a violent prolonged shock that jerked the small bunk-house in an alarming manner and made an infernal noise. Shelves were cleared of books, bottles, papers, etc., and water in cans on the floor was scattered about. A number of men present had been through the San Francisco shake of 1906, and it was, and is now, the general opinion that the Kennedy shake was more violent than that one.

The feature that produced much nervousness was the fact that the shocks did not cease, but one followed another, at frequent intervals, all night, connected by periods of uneasy feeling, slight tremblings and waves. The sage-brush was good camping-ground for the thirty or forty people of the town during that night and many slept outside for some time.

Next day the shocks were felt at close intervals. Some were timed at noon and occurred at less than minute intervals. An estimate based on frequency showed that during the three months following there were at least 500 shocks, mostly light ones, but many moderately heavy.

The visible signs left in Kennedy were slight, consisting of small cracks in soft ground, ore-piles flattened out, and rocks displaced on the slopes, but a rocky summit on the ridge above town was whipped to pieces, thousands of tons of rock rolling down into a gulch on the western watershed.

The most pronounced evidence of the disturbance is to be found on the east side of Pleasant valley, just where the detritus meets the steep mountain slopes. The valley is about three miles wide, covered with sage-brush, with steep slopes on the east and gentle ones on the west. The slip or settlement varies from 5 to 12 feet, measured vertically, and as much as 8 ft. measured horizontally. At places the bedrock is visible, showing signs of the movement. The line follows the contour of the hills closely, and at a few points there are two slips, one above the other. Its length is about 25 miles, and it extends along that part of the valley where the slopes are the steepest, disappearing gradually at both ends where the hills flatten. The indications are that this slip was a result of the earthquake and not the cause,

although it may have contributed to the length of the shock.

A ranch-house within 300 yards of the heaviest slip had much less shock than Kennedy, although only five miles from the nearest point, and the inhabitants did not know about the slip until next morning. The floor of the valley was, in places, cracked and displaced; water, carrying fine sediment, flowed out.

The photographs, taken on October 10, will give a general idea of the appearance of the slip. Streams flowing from the mountains into the valley were much augmented, but in Grass valley, near Winnemucca, the flow did not change much, and at one point a spring was cut off.

The number of shocks and the quietness of the surroundings favored a detection of the sounds that usually accompany an earthquake. It is stated that the velocity of an earthquake shock is about 200 miles per minute, which is about fifteen times the velocity of sound in air. The query is, why is the rumbling sound heard, in many cases, before the shake is felt? The sounds here have varied from sharp explosive to low rumblings, like distant thunder, generally heard a fraction of a second before the shock was felt. There have been many instances of sound without an appreciable shake, a few of shake without noticeable sound, and some of shake preceding sound. The fact that, as a rule, the sound precedes the shake and the further fact that there have been numerous cases of sound without appreciable shock lead to the suggestion that an earthquake may produce sufficient sound to be heard yet be so light as not to be felt. Under conditions prevailing here sound carries far.

[In the Bulletin of the Seismological Society of America for December 1915 we find an account of the Pleasant Valley earthquake by J. Claude Jones. He states that the fault appeared at the surface "as a fresh vertical scarp from 5 to 15 feet in height, running for over 22 miles along the junction of the alluvial apron and the base of the Sonoma range." The earthquake was as severe as that of 1906 in California, but the damage was small because the centre of disturbance passed through a sparsely populated region. If it had traversed a densely populated country, this earthquake would have ranked among the most terrible in history. An observer at Kennedy describes how he was suddenly awakened from sleep by "a great roar and rumbling" and how he was "thrown violently out of bed and buffeted in all directions." One effect of the earthquake was to increase the flow of streams and springs three or fourfold throughout northern Nevada. Immediately afterward the office of the State Engineer received over 50 applications for new water-rights. —EDITOR.]

Gold received at the San Francisco mint during May amounted to 197,535 oz. fine, 11,719 oz. of which came from Australia. There was 104,111 oz. sold. Silver receipts were 97,473 oz. Coinage was only \$9500 in one-cent pieces, and \$21,000 in one-centavos for the Philippines. The vaults contain \$371,681,472.13.

THE EARTHQUAKE-RIFT (WHITE LINE ALONG MOUNTAIN SIDE).

NEARER VIEW OF THE RIFT, SHOWING FAULT.

Copper Metallurgy at Garfield, Utah

By L. O. Howard

THESE notes are based on a visit to the Arthur mill of the Utah Copper Company and to the plant of the Garfield Smelting Company, at Garfield, upon the occasion of a recent excursion by the Utah section of the American Institute of Mining Engineers.

ARTHUR MILL. This has 13 sections enclosed in a structure 587 ft. long by 325 ft. wide. In it are treated daily 10,000 to 12,000 tons of low-grade copper ore from Bingham, the remainder of the 25,000 tons mined by the company being treated in the Magna mill, after which the Arthur is modeled. The Arthur mill was originally the property of the Boston Consolidated and, before it was taken over by the Utah Copper company, had attracted much attention as an exponent of the Nissen stamp. There were over 300 of these, which were used after the coarse breakers to prepare the feed for the Wilfley tables. A comparatively simple flow-sheet characterized the plant at that time. The finely crushed ore was delivered to 3-compartment hydraulic classifiers. The first two spigots were tabled, making finished concentrate and tailing. Middling was passed over Johnston vanners, likewise making a finished concentrate and tailing. After thickening, the slime was treated on other vanners for final products.

Construction of the old mill was along the most modern lines. Driving-shafts were placed close to the machines, and belting minimized. Pipes and launders were carried in tunnels beneath the floor. There were no elevators or centrifugal pumps. All machines had individual clutch-drives. The floor was of wood, special precautions being taken against spillage. The launders had high sides and steep pitches. Vanner belts had high flanges. The absence of elevators aided in keeping the floor dry. Launders were fitted with plate-glass bottoms.

The capacity of the plant was given in 1909 as about 2100 tons per day of ore containing 1.58% copper. The recovery was 21.8 pounds of copper per ton of ore, 80% of the total concentrate, containing 85% of the total copper, being made on the Wilfleys. After the merger with Utah Copper in 1910, a test lasting 30 days was made under identical conditions in the Magna and Arthur mills, resulting in the decision to remodel the Arthur mill to follow the process used in the Magna plant, in which a greater tonnage was treated for a higher recovery and at a lower cost. Without increasing floor space, the capacity was raised from 3000 to 8000 tons and finally to about 12,000 tons per day. The best of the constructive features were retained.

The increased capacity was obtained by the use of Garfield tables over which an enormous quantity of material was passed, with no attempt to make any fin-

ished products in the first stage. The concentrate was cleaned on Wilfleys, the tailing classified in the improved Richards-Janney mechanical-hydraulic classifiers, the finer sizes going to vanners while the coarse was re-ground in Chilean mills, re-classified and re-roughed on Garfield tables, from which the tailing was returned to the primary classifiers. The concentrate from the second set of tables was classified and cleaned on Wilfley tables and Johnson and Frue vanners.

The ore is received in 50-ton cars on the high line and dumped to the receiving-bins. These are 300 ft. long, 34 ft. wide, and 20 ft. deep, with a steel frame and wooden lining. They are equipped with scalping grizzlies, and the fine ore is by-passed around the coarse breakers. The bins have 80 discharge openings in two rows, delivering to chain-belt feeders driven by ratchet and pawl. Thirty-inch flat belts take the ore to the coarse-crushing plant at the end of the bins, where it is reduced to $\frac{3}{4}$ -inch in No. 8 Gates crushers and 72 by 20-in. rolls, this section being equipped with the necessary grizzlies and trommels to increase the percentage of coarse feed to the crushers. From the coarse rolls the ore is taken by two 18-in. belts up a 20° incline to the fine-ore bin, into which it is distributed by two self-tripping 18-in. conveyors. This bin is 580 by 22 by 20 ft. and has a capacity of 13,000 tons. The bottom is flat.

The ore is fed automatically to impact-screens, which appear to be about 8 or 10 mesh. The oversize is crushed in 37 $\frac{1}{2}$ by 15-in. rolls and elevated to the screens. The undersize is treated on Garfield roughing-tables, the concentrates being classified and cleaned on Wilfley tables and Isbell vanners. Each section has 6 Garfield and 2 Wilfley tables, and 4 Isbell vanners for the primary concentration.

The tailing from all these tables is elevated to the primary classifiers. These have four spigots and an overflow. The pulp from the first two spigots is re-ground to about 40-mesh in two 6-ft. Garfield mills, and is again classified for a second roughing on three Garfield tables, after which the tailing returns to the primary classifier. The product of the 3rd and 4th spigots of the primary classifier is re-classified in two 5-spigot secondary classifiers. The coarse product is treated on two Garfield tables, where the first clean tailing is made. The fine products go to 24 Isbell vanners, making finished concentrate and tailing. The concentrate from the Garfield tables is elevated to a classifier the coarse from which is finished on a Wilfley, and the fine dewatered in 24 Callow cones before final treatment on 36 Johnston and Frue vanners.

The flow is as nearly gravitational as it is possible to make it. The successive tables are strung out down the

section, each table-treatment being on a separate floor.

The above is substantially the treatment now given in 12 sections. In the 13th much experimental work has been undertaken. The fine crushing has been simplified. The impact-screens, rolls, and roll-return elevators have been eliminated, and crushing is done in two Marcy ball-mills, part of the product going to the Garfield tables and through the section, as in the other twelve. The slime-vanners have been taken out, and all of the material formerly treated there, as well as the finest material from the Marcy mills, is subjected to flotation. Much testing with oils and with modifications of standard practices, has been conducted, concerning which no data are available for publication, since the process is still in the experimental stage. The Janney flotation machines are used, the latest development including the Callow modification. In section No. 13 there are 12 mixing-cells and 30 roughing-machines, arranged in 6 units of 5 each, although the arrangement is flexible and may be changed if conditions indicate a different grouping as desirable. The machines in each unit are in cascade. Each machine, whether mixer or roughing, is driven by an individual 10-hp. motor, set on a vertical shaft in the middle of the machine. On each side of the agitation-compartment is a flotation-box, which is equipped with Callow mats for the introduction of air, thus combining mechanical and air agitation. The receiving compartment is equipped with a pulp-overflow to maintain an even feed, and the concentrate discharges automatically. A thick light froth was produced under the conditions obtaining at the time of inspection.

The feed to the flotation department is first dewatered in a 75 by 12-ft. Dorr thickener, elevated on a timber structure, from which the pulp is pumped to six units of two mixer-cells in series. Construction is under way to provide six of these large thickeners. After violent beating in the mixer-cells, the pulp flows to the first of the roughing-cells, oil being introduced at such points as is advantageous. Tailing from the first cell goes to the next lower machine, and so down through the series. All of the concentrate is received in a common launder delivering to the cleaning-department on a lower level. The machines used for cleaning are of the straight Janney type. No air-mats are used. Instead, the froth is skimmed by a board driven by eccentrics, the froth being much heavier and more compact than on the roughers. Whereas the roughing-machines were arranged with all the cells in a single line, end to end, the cleaning-machines, each of three compartments, are set side by side. They deliver concentrate from both sides, and may be operated in series or in parallel. Most of the cells at present make a finished concentrate, only the last few returning middling to the head of the series. Middling may be taken off any machine by swinging into place a hinged board that diverts the overflow to a launder.

Another set of these machines is provided for cleaning low-grade vanner-concentrate. Concentrate containing 8% copper and about 80% insoluble is brought up to 22 to 25% copper, thus allowing the vanners to

make a larger amount of low-grade concentrate and clean tailing, with a higher recovery than is possible with the vanners in the other sections.

The part played by flotation in the Arthur mill therefore is as a substitute for vanners in handling current slime, and as a cleaner for low-grade concentrate, from the Isbell vanners in particular, which in reality now treat a fine sand only, the slime having been separated and diverted as mentioned. This particular application may be regarded as the reverse of the customary treatment of tailing, in plants where the tables are run to make as high a concentrate as possible, depending on flotation to recover any metal lost in tailing. The advantage of removing the large bulk of tailing from the process is made possible by the low grade of the ore, and throughout the plant it will be noted that this practice is followed, becoming the principal factor in augmenting the capacity of the plant. All concentrate is laundered to drain-bins below the mill, and is reclaimed by clam-shell buckets loading into railroad-cars.

Excellent metallurgical results are being obtained in the experimental section, and, incidentally, on an ore the principal mineral of which is chalcocite, not so long ago regarded as unsuited to flotation. It needs no imagination to see the scrapping of approximately 1000 vanners and about 700 cone-tanks, in the two mills, as well as the elimination of the impact-screens and several sets of rolls and elevators.

An idea of the magnitude of the operations can be gained from the following list of machines in use before the adoption of flotation: 182 Garfield roughing-tables, 26 Wilfley tables, 832 vanners, 92 Richards-Janney classifiers, and 364 dewatering cones.

GARFIELD SMELTER. This treats oxidized and sulphide ores from Bingham and other districts in Utah, Idaho, Montana, Colorado, Nevada, California, Oregon, Wyoming, and Arizona, silicious ore from Tintic, and concentrate from the Utah Copper mills. The daily charge to the furnaces consists of about equal amounts of crude ore and concentrate.

The crude ore, with foreign matte, is unloaded from gondola-cars to bins or to belts that deliver to the top of one of two sampling-mills for oxidized ore, or to one of a similar pair for sulphides. These mills have a combined capacity of 2400 tons per day. They are enclosed in two buildings 83 by 70 by 72 feet.

The oxidized ore and the coarse sulphide ore from the sampler are taken by belt to the blast-furnace bins, of which there are four of a capacity of 2500 tons each. Concentrate is shovel-sampled to a system of conveyor belts delivering to 25,000-ton bins, where the fine sulphide ore from the sampler is also received. Coke, blaststone, slag, matte, and miscellaneous material are delivered by railroad-cars to long bins, arranged in four rows, 190 by 25 by 20 ft., divided into 28 600-ton compartments. These form part of the same structure with the blast furnace ore bins. Eight trolley tracks below serve the blast-furnaces from here.

The system of handling ores and fluxes is flexible

Material may be unloaded into bins, or upon belts delivering to the sampling-plants, or to blast-furnace bins, or may go directly by belt to the fine-ore bins.

There are four 20-ft. by 42-in. blast-furnaces equipped with oval settlers 25 by 15 ft. Each furnace has 22 4-in. tuyeres on a side. Jackets are 10 by 6 ft., six on each side, and one at each end. Twenty thousand cubic feet of air per minute is used per furnace at a pressure of 40 oz. The ore, flux, and coke (7%, made from Sunnyside coal) are loaded into 5-ton cars from the blast-furnace bins. Trains of five cars run to the top of the building, and deliver the charge through side-doors of the furnaces. The doors are operated by compressed air. The ore-column is 15½ ft. high. Formerly, with a column of 12 to 14 ft., the furnace was fed through a set of chutes delivering below the level of the feed-floor. The openings in the furnace on this floor were confined to end-doors through which barring-off was done. Only two furnaces are now in operation. With the increased delivery of flotation-concentrate, and the higher efficiency and lower cost of the coal-dust fired reverberatories, it is only a question of time when the coarse ore will be crushed and smelted in reverberatories.

Slag flows continuously into 10-ton slag-cars, operating in a tunnel below the floor-level. Matte is tapped to 10-ton ladles as required by the converters.

Alongside the blast-furnaces are six reverberatories, four of which are 112 by 19 ft., one is 112 by 20½ ft., and another is 120 by 20½ ft., with an average capacity of 460 tons each of ore and concentrate per day.

Concentrate is prepared for the reverberatories in 34 roasting-furnaces having a capacity of about 2400 tons per day. Sixteen are 6-hearth McDougalls, 18 ft. diam. Fourteen are 6-hearth McDougalls, 19½ ft. diam., and four are 7-hearth Herreshoffs, 19½ ft. diam. All are 18½ ft. high, and have air-cooled shafts and arms.

Larry cars operating on tracks over the reverberatories bring the calcine from the roasting-plant to the charge-hoppers of the reverberatories. Part of the furnaces are charged from hoppers on the centre-line of the furnace, and part through slots along the walls. The best results have been obtained by a combination of the two methods and it is intended to equip all furnaces with central hoppers and side-slots.

Although the plant was equipped with an elaborate oil-firing plant, the furnaces are now fired by coal-dust. Utah slack-coal is now used on the four furnaces in operation. It is received in gondola-cars and dumped to bins near the ground-level, from which it is taken to a 60-ft. Power & Mining Machinery cylindrical dryer, having a capacity of 225 tons per day. Moisture is reduced from 8 to 1%. An elevator and belt-conveyor deliver to bins over four Raymond pulverizers and vacuum-separators, which grind the coal so that 90% passes 100-mesh. The vacuum system lifts the coal to screw-conveyors, which deliver to the coal-hoppers above the furnaces. The coal is fed to Sturtevant burners by the usual methods.

The air in the furnace clears rapidly as the flue-end

is approached, and combustion is perfect. There is no trouble from ash-blankets on the charge, nor is the draught through the waste-heat boilers impeded. Three Stirling boilers are arranged in parallel in each reverberatory flue. About 400 horse-power is generated at each furnace.

The system has given excellent satisfaction. Furnace-capacity has been increased and the fuel-ratio decreased to 7:1. The minor advantages are many. The total consumption of coal is 300 tons per day for the four furnaces, which in 1915 averaged 459 tons of charge per day each. The oil-burning equipment is maintained at full efficiency as a reserve. In case of trouble with the coal-firing apparatus, it is only necessary to swing in the oil-burners and continue firing without interruption. So far no serious accidents have occurred. Care is taken to keep the pulverized coal in small units, and watch is kept for incipient fires, which have been easily and quickly extinguished.

Slag is tapped from the furnaces once per shift, 8 to 10 pots at a time. It is taken to the dump by steam-locomotives. About 1200 tons per day is made. Matte is tapped from near the fire-end into 10-ton ladles.

The coal-pulverizing plant, blast-furnaces, and reverberatories are strung out in a row along one side of the main building, which is 840 ft. long, 305½ ft. wide, and 92 ft. high. In the south-east corner are the blast-furnaces. At the west end of the south side are the reverberatories. On the north side opposite the blast-furnaces are six converter-stands. Three 60-ton Shaw cranes operating in a 60-ft. aisle serve the furnaces and converters.

The converters are of the Pierce & Smith, horizontal barrel, type, lined with magnesite brick. They are 10 by 24 ft. outside measurement, and 7 by 21 ft. inside. There are 37 1½-in. tuyeres on each converter. Tilting is by means of a hydraulic piston operating a cable wrapped around the converters. The charge to the converters consists of 120 tons of matte and 30 tons of silicious ore from Tintic. Three converters are in operation, producing about 60 tons of blister copper per day each. Slag is taken by cars to a casting-machine, making cakes 60 by 17 by 4 in., which discharge automatically after cooling into bins or chutes delivering to railroad-cars, which are hauled to the blast-furnace bins at a higher level.

Copper is handled by ladle and crane to an oil-fired cylinder, from which the pouring ladle is filled. There are two Walker casting machines, 24 ft. diam., carrying 26 molds. The cast-copper, 99.1% pure, is shipped to Perth Amboy or Baltimore for refining.

Independent flues are arranged for blast-furnace, roaster, reverberatory, and converter gases. The blast-furnace flue consists of three sections. One is of brick, 2300 ft. long and a cross-section of 320 sq. ft.; another is of steel, 620 ft. long, with a cross-section of 215 sq. ft.; and the third is of brick, 600 ft. long and 215 sq. ft. in cross-section. Gases from the blast-furnace pass through the flue to a dust-chamber, 300 ft. long and 920 sq. ft. in

section. The chamber has two 35-ft. sections and one 10-ft. section hung with vertical wires at intervals of 12 in., and provided with a mechanical shaking device. From the dust-chamber the gases pass to a new brick stack, 22 ft. diameter at the top, and 350 ft. high, or 430 ft. above the furnace-floor.

The flue from the roasting-furnaces, made of brick, is 1600 ft. long and 320 sq. ft. in section. Roaster-gases are conducted to the old stack, which is of brick, 30 ft. inside-top diameter, and 300 ft. high or 500 ft. above the floor of the reverberatory furnaces, this stack receiving gases from the latter also, after they have passed through the waste-heat boilers by means of a brick flue of which 1200 ft. has a section of 320 sq. ft., and 775 ft. a section of 360 sq. ft. Gases from the converters pass through 900 ft. of steel flue, 227 sq. ft. in section, to the Cottrell plant. After treatment in this plant they pass to the new stack. The Cottrell plant receives only gases from the converters; they can be handled at the rate of 250,000 cu. ft. per minute, in a chamber having a cross-section of 1775 sq. ft. and 105 ft. long, in which are 2500 5-in. pipes, 10 ft. long. The pipes are arranged in seven sections of 360 each. No. 10 iron wire is used for discharge-electrodes, which carry a voltage of 25,000. The power consumed is 60 to 80 kw. Several tons of fume daily are recovered that will assay over 50% lead. The fume is removed from the pipes by shutting off the gas from each section in turn, and striking the pipes with swinging hammers operated by a lever at the side. This equipment was the first of the multiple-pipe type, and has smaller tubes and a lower voltage than is the practice in later equipments. The high content in lead, the variation in the gas analysis, and the high temperature, alone or together, prevented the use of a bag-house, even with the aid of some neutralizing method, as it was impossible to feed the neutralizing agent automatically. In blowing leady matte it has been the custom to waste the lead. The application of the Cottrell process in the recovery of this lead is, therefore, of especial interest. An interesting description of the plant and the tests that led to its adoption may be found in the Transactions of the A. I. M. E., Vol. XLIX, page 540. It was written by W. H. Howard, consulting metallurgist to the company.

EXPORTS from the United States increased from \$2,484,000,000 in 1913 to \$3,555,000,000 in 1915, which is a gain of more than a billion dollars over a former total of about 2½ billion dollars. "Astonishing as it may seem," states the chief of the Bureau of Foreign and Domestic Commerce, "the increase in the export of munitions of war has been less than the gain in secondary war-supplies; while the largest increase has been in materials that have no direct relation to the activities of belligerent nations." Exports from the United States to South America increased 32%; those to Central America 34%; to Africa 51%; to Asia 135%; to Australia 17%; and to Canada 23%. One of the greatest gains that American industry is making in trade with foreign countries is that of good-will.

Determination of Antimony

By Harel R. Layng

The following method is a modification of a process published in the appendix of Lowe's book. The modified method has been used by me in making over 1500 determinations of antimony contained in ores, alloys, and compounds, and it is the result of numerous experimental tests. The application of this method will enable a chemist to make as many as 50 determinations in a day. The method produces reliable results on samples containing arsenic or tin, and in this respect it differs greatly from the unmodified method, which is quite untrustworthy in the case of samples containing arsenic or tin. In order to produce reliable results it is necessary to follow the method closely.

SOLUBLE SUBSTANCES (alloys and sulphides). Place ½ gm. of the finely pulverized sample in a dry 300 cc. tall glass beaker; add 25 cc. hydrochloric acid and bromine solution (20 cc. of Br dissolved in 500 cc. HCl); cover with watch-glass and heat until the solution is complete, being careful always to have bromine present during the solution of the metal. Heat to boiling for a few minutes to drive off the excess of bromine. Cool to room temperature, add carefully 8 gm. (measured to within ½ gm. will answer for most purposes) of pure dry anhydrous sodium sulphite, then add 25 cc. hydrochloric acid in such a manner as to rinse the sides of the beaker. Cover with a watch-glass and place on stove, producing a heat sufficient to maintain the temperature of the assay at 108 to 109°C. When the assay has had exactly 50 minutes of such heat treatment add 40 cc. boiling hot dilute hydrochloric acid (1 part HCl to 2 parts H₂O) and continue heating for five minutes. Rinse the bottom of the watch-glass and the sides of the beaker with as little hot water as is necessary, add 4 drops of methyl orange solution (10 gm. to 100 cc. H₂O) and titrate the nearly boiling hot assay with a standard solution of potassium bromate, adding the bromate solution as rapidly as possible, avoiding such a rapid addition as will cause localization of reactions, stirring vigorously all the while; continue the rapid addition of the bromate until the pink color of the assay begins to fade, then proceed more slowly, finally finishing the titration drop by drop, stirring vigorously meanwhile. The end point is the disappearance of the last trace of pink coloration, or, in the absence of color-forming substances, such as salts of iron, the assay liquid is water-white. In the absence of iron or like salts, a yellow colored solution indicates that the titration is overdone.

Standardize the potassium bromate solution against pure pulverized metallic antimony, proceeding with the method exactly as before stated. The standards should check exactly. Run blanks on the chemicals, using the same amounts and proceeding exactly as in the case of the sample. The blanks sometimes require as much as ½ cc. potassium bromate solution. 1 cc. of KBrO

5 mg. Sb), depending upon the chemicals used. The bromate solution should be standardized often, and for particular work when the stove does not give a steady heat the standards should be run with each batch of assays placed on the stove. For ordinary work when an electric stove is used the solution does not require standardizing more often than once in three or four days. The titration is based on the following reaction:

The excess of potassium bromate, to finish the titration, oxidizes the methyl orange indicator, thereby destroying the pink coloration due to the action of methyl orange with hydrochloric acid. The standard potassium bromate solution contains 2.191 gm. KBrO_3 per 1000 cc. H_2O (1 cc. = 5 mg. Sb).

INSOLUBLE PRODUCTS (oxidized ores). Place $\frac{1}{2}$ gm. of the finely pulverized sample in a 20 cc. porcelain crucible containing about 6 gm. of an equal mixture of sulphur and sodium carbonate; mix well and cover the mixture with about 2 gm. of the sodium and sulphur flux. Cover with a porcelain cap and heat gently until the mass is fused; do not prolong the heating. Considerable experience is required to conduct this fusion method and I would advise that its use should be preceded by a number of experiments in order to obtain knowledge of the proper temperature at which to conduct the fusion. High heat or prolonged heat causes considerable loss of antimony, while, on the other hand, insufficient heat or time causes low results. Dissolve the fused mass with hot water; filter from solids; heat the filtrate to near boiling and add sufficient dilute hydrochloric acid ($\text{HCl} + 2\text{H}_2\text{O}$) to render the assay slightly acid. The mixture is stirred for a moment and allowed to stand warm with occasional stirring, to coagulate the precipitate of antimony sulphide, for about 10 minutes; add a little H_2S water and filter, using preferably an aluminum filter-cone. Wash with H_2S water. Rinse the precipitate from the filter into the 300 cc. tall beaker that originally held it with as little hot water containing traces of H_2S as possible; decant the excess of water from the precipitate in the beaker. Drive off the balance of the water from the beaker by means of moderate heating, finally finishing on a water-bath. Place the beaker containing the almost dry precipitate under the funnel containing the filter with its traces of antimony sulphide and pour 25 cc. warm hydrochloric acid and bromine solution through the filter little by little to dissolve traces of antimony; then continue to treat the assay according to the procedure customary with soluble ores as described previously.

REMARKS. It is unnecessary to filter from insoluble residue or free sulphur unless their presence is so marked that they obscure the titration. Small amounts of iron do not interfere. If iron is present to such an extent that it obscures the end-point or bleaches the methyl orange indicator it will be necessary to remove it by precipitating the antimony as a sulphide and filtering off the iron solution; in such a case proceed to get a

practically dry antimony sulphide precipitate and treat it just as if it were the sulphide from the fusion. With practice an operator will be able to conduct the titration without removing the iron, in cases of samples containing as much as 10% iron. The antimonious chloride and methyl orange are oxidized by the potassium bromate before the ferrous chloride is attacked. Zinc, lead, arsenic, or tin do not interfere. The arsenic and tin are volatilized during the 50-min. period of heating the solution containing sodium sulphite. Some antimony is volatilized during this period but its loss in this manner, which is constant, only amounts to 3 mg. when 500 mg. of antimony is present, which loss is corrected by the standardization. In cases where extreme accuracy is desired, it will only be necessary to have present the same amount of antimony in the standards as is present in the assay, in order to compensate for the loss taking place in volatilization.

The determination of arsenic in the presence of antimony appears to bother many chemists, judging from the returns given by different chemists on samples divided among them. I have made many experiments along this line and found that Lowe's modification of the Pierce method is absolutely reliable.

The following tests, a few of many that I have conducted, were run in duplicate and are given to show the value of the method:

A										Cc.	
No.	Mg. Sb	Mg. As	Mg. Sn	Mg. Fe	Mg. Zn	Mg. Cu	Gm. Na ₂ SO ₄	Min. Heat			Bromate
1	250	8	50			49.6
2	"	50	8	50			49.6

Letters indicate that a different standard solution was used for each series of tests.

BARYTA, or barite, has been a bugbear to many operators in Summit county, Leadville, and in the San Juan. Now a new product called 'lithopone' is being produced at Leadville by the Western Zinc Oxide Co., this product being a mixture of zinc oxide and barite. It forms a pure white pigment that is used as paint in interior decorations, and to some extent in the manufacture of linoleum and rubber goods. The market for baryta has been good for the past year.

Mining in Utah

By L. O. Howard

Dullness in the metal market has not diminished activity in mining in this State. Interest in zinc is increasing. The success scored at Promontory, where a dividend-paying mine was opened at grass-roots, has spurred other prospectors with the hope of finding 'poor men's' mines. Zinc ore has been mined in the sandstones of south-eastern Utah, and a few cars shipped. About 38 miles west of Salt Lake, in Timpie canyon near Grantsville, there has been a rush of prospectors for zinc, and from one mine shipments are being made that will average about 32%. In Boxelder county, 28 miles north of Ogden, 50 tons of zinc ore is held for shipment at one mine, and others are being opened up. This mine is only $1\frac{1}{2}$ miles from an electric railway, and other facilities are said to be available. Zinc is also known to occur in the Santaquin district, south of Salt Lake City, and development is proceeding there.

Among the smaller operators much activity continues. The Utah Ore Sampling Co. has three plants at work. The one at Murray is sampling 500 tons of ore daily, and another plant of equal capacity is planned. At Silver City the plant is crowded with ore from the Tintic mines. A heavy tonnage is also being sampled at Park City. Inasmuch as a large proportion of this ore comes from the small mines, a healthy condition is evident.

The State Conservation Commission announces that it has arranged with the University of Utah for the establishment of a free information bureau, which will determine for prospectors the nature of any ore or mineral they may send. It is not intended to compete with regularly established assayers by making quantitative analyses, but the prospector will be aided in determining if he has found any unusual minerals.

Tungsten mining is at a standstill. Where low-grade ore was being mined and sent to custom-mills, operators face a decided loss, and several milling projects are held in abeyance. The ardor of the search for profitable antimony mines has cooled, although under reasonably favorable conditions the price is still ample to permit profitable exploitation. The potash industry is flourishing. The Mineral Products Co. at Marysvale continues to increase its production, while seeking to attain higher extraction. The principal vein is said to be opened for a length of 1000 ft., the last 800 ft. of which is 20 to 25 ft. wide, and is composed of nearly pure alunite. The Florence Mining & Milling Co. has selected a mill-site near the railroad and preliminary work has been started on a 100-ton plant that is expected to produce 10 to 15 tons of potash salts daily. For the present the ore will be hauled by teams from the mine, 13 miles distant.

During May the Lakeview mine shipped its usual tonnage of zinc ore from Promontory. Indications are that this district will become a producer of lead and copper ores also. The Lakeview has done enough de-

velopment on its lead ore-shoot to commence shipments. Another property has opened a vein of ore that will assay 15% copper, and while this average may not be maintained it is probable that a good tonnage of shipping ore will be developed.

The summer weather has stimulated activity in outlying portions of the Park City district that have long been idle; for instance, at the American Flag, where a new company has been formed to undertake thorough exploration; also at the Daly Judge Extension, where the old workings are being cleared with a view to operation; and at the Iowa Copper, at the head of Thayne's canyon, on Scott hill, near the crest of the Big Cottonwood divide, which has been made the subject of a reorganization to provide funds for development.

Geologists of the Survey have started a more thorough study of the Alta-Cottonwood-American Fork district. F. F. Hinte, of the geological department of Lehigh University, is associated with the Government men in the work. His selection is a happy one, for to him is due the only comprehensive report on the stratigraphy and structure of this region, and his collaboration may be expected to aid in clearing some of the points of difference appearing in various descriptions of the district. Concerted effort by local mining men is responsible for the prompt beginning of this work. It is to be hoped that the publication of results will follow as promptly, and that these men will not be placed on other work before they have completed their task. There appears to be a tendency recently to avoid the repetition of the Butte and Park City blunders, so that the information may be expected to be available before another spring.

D. C. Jackling of the Utah Copper has announced that in two or three weeks work is to begin on the first 2500-ton unit of the long-expected leaching-plant. Details of the process are withheld, but it is known that sulphuric acid will be provided by the plant that is being built to utilize the Garfield smelter-smoke. About 40,000,000 tons of oxidized ore containing 1% copper is available for treatment.

The overloading of the lead smelters has resulted in a demand from them that Tintic shipments be curtailed. The large producing mines will probably confine their shipments to the better class of ore. The Eagle & Blue Bell was first forced to reduce shipments from 150 to 100 tons daily, and later to 50 tons. The Mammoth and Chief Consolidated have also had to curtail. Many miners have been laid-off, but as many as possible are being employed on additional development work. The Centennial-Eureka, owned by the United States Smelting company, will continue to ship at a maximum rate.

Shipments from Big Cottonwood canyon are still curtailed owing to the slowness of contractors in improving the road. It happens that the part that is causing delay was a typical mining operation, so that an effort to do the work cheaply has delayed transportation and hampered the mining companies unnecessarily. It is evident now that it would have been better for the mining companies to do this portion of the work themselves.

Blasting Practice at Chuquicamata, Chile

By Howard W. Moore

The disseminated ore at this mine is found in coarse grano-diorite. The mineralization is chiefly along the planes of fracture, but it has impregnated the entire country-rock. The important minerals are: chalcantithite ($\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$); brochantite ($\text{CuSO}_4 \cdot 3\text{Cu}(\text{OH})_2$); krolnikite $\text{CuSO}_4 \cdot \text{Na}_2\text{SO}_4 \cdot 2\text{H}_2\text{O}$; pisantite $(\text{FeCu}) \text{SO}_4 \cdot 7\text{H}_2\text{O}$; and atacamite $\text{Cu}_2\text{CH}_3\text{O}_2$. The average copper content of the ore is 1.65%. Steam-shovel benches 40 to 100 ft. high have been laid out parallel with the long axis of the orebody on a 3% grade.

The first method of breaking the ore involved the use of vertical churn-drill holes, set in rows that were 40 to 50 ft. apart, with the holes in each row about 25 ft. apart. These holes were drilled to a depth a few feet below the grade of the shovel-bench and 'sprung' five to seven times with 60%, or sometimes 75%, dynamite. A chamber 6 to 8 ft. diameter was formed by this springing, and the chambers were then loaded for the final shot. The cost of this drilling proved so excessive that it was abandoned, and blasting is now done by means of 'tunnels,' a method found more successful and economical than the original practice. The churn-drilling cost about \$9.80 per foot, while the tunnel-work, including

sinking, cross-cutting, and driving, is costing only \$5 per foot, and all of this work is accomplished by hand-drilling.

The tunneling is done with considerable precision. Shafts are sunk in several well-chosen parts of the orebody, to a depth of 3 metres below the grade of the shovel-bench. From the bottom of these shafts, cross-cuts are run parallel with the short axis of the orebody, and drifts are extended from the cross-cuts parallel with the long axis of the orebody, and about 15 metres apart. These drifts receive the charges of explosive; the method of loading is represented in Fig. 1. Beginning at a face of the drift, 10-metre centres are measured for the powder chambers, and the charges are calculated for each chamber by means of cross-sections through these centres, as shown in Fig. 2. By plotting the cross-section to scale, and drawing the line of least resistance, it has been found by practice that approximately 463 lb. of black powder should be used for every metre as measured on this line of least resistance. For dynamite of 60% strength, this figure should be divided by 2.64.

The powder is loaded in sacks of 100 lb. each. It may be loaded in cans, but is naturally more compact if

Diagram for Tunnel Blasts

loaded in sacks. The interstices between the sacks are filled with sand or any kind of convenient packing. In the centre of the charge, two boxes of 60% dynamite are placed, which serve as the 'primers.' One electric cap is carefully connected with each box of dynamite, and the lead-wires are carried from the primers, along the floor of the drift, in grooved stringers (2 by 3 in. material with $\frac{3}{4}$ -in. groove) provided with $\frac{1}{2}$ -in. covers carefully nailed-down after the wires are in place. A cross-section through the centre of the charge is shown in Fig. 3. The lead-wires and stringers are cut long enough to reach from one charge to the next, and after the chamber has received its charge of powder, broken rock is filled-in closely from wall to wall and from floor to roof. Charging of the other chambers is done in a similar manner.

It will be noticed that two separate series are carried. This is done to prevent a misfire, which might result from a broken circuit in one or the other series. Each series is on a different transformer. From careful experiments it was found that for a series of 20 caps, a current carrying 0.75 amperes under 110 volts should be used for a successful 'fire.' Each cap showed a resistance of about 2 ohms, that is, the cap plus about 30 ft. of fuse-wire. The present practice of wiring a charge is shown in Fig. 4.

After the drift is loaded, the cross-cut leading from this drift back to the other workings, is filled with broken rock to within 4 metres of the first drift back. At this point a solid concrete bulk-head is put in, not so

much because of the resistance it affords, as to seal hermetically the workings back of the shot, for preventing the filtration of gases after the explosion. The handling of such large quantities of explosive is somewhat hazardous, but the work is so systematically and carefully superintended that, to date, no accidents have occurred through carelessness.

[The first method tried and discarded, that of vertical churn-drill holes, is used successfully at the Nevada Consolidated copper mines, where the ore is softer than at Chuquibambata. EDITOR.]

IRON-ORE mined in the United States in 1915 amounted to 55,526,490 tons, worth \$101,288,984 for the 55,493,100 tons shipped. This is the greatest output in any year save 1910 and 1913, and 14,000,000 tons more than in 1914. The average value was \$1.83 per ton, according to the U. S. Geological Survey. There were 27 producing States, some of them for flux only. Minnesota led with 33,464,660 tons, Michigan produced 12,514,516 tons, Alabama 5,309,354 tons, Wisconsin with 1,095,388 tons, and New York with 998,845 tons. Taking the districts, Lake Superior produced 85%, and Birmingham 8.5%. Seven mines including the Mahoning, Hule-Rust, and Red Mountain yielded over 1,000,000 tons each, 2,311,940, 2,307,195, and 2,138,015 tons respectively. The ratio of pig-iron to iron ore was 53 15%. The output of iron was 29,916,213 tons, worth \$13.21 per ton at furnaces.

CONCENTRATES

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

BRASS as now made for cartridges contains from 67% copper and 33% zinc to 71% copper and 29% zinc.

WATER-POWER of the world is estimated at 700,000,000 horse-power; 21% in Africa, 21% in North America, 14% in South America, 32% in Asia, 2% in Australia, and 10% in Europe.

COST of development in the Hollinger mine, Ontario, is as follows: diamond-drilling, \$1.60 per ft.; cross-cutting, \$6.40; shaft-sinking, \$42.32; driving, \$10.10; raising, \$16.17, and winzing, \$39.20. These costs are low for the district, notably those for diamond-drilling and cross-cutting.

NAILS driven in wood that is exposed to alternate wetting and drying are likely to work out. The wetting swells the wood and moves the nail, which does not return to its original position when the timber dries. It is for this reason that timber structures bolted together and exposed to weather require screwing up at intervals.

SILVER ORE at the Rosario mine, Honduras, averaged 16.97 oz. per ton in 1915. In recovering 87.45% of this there was used 3.93 lb. of sodium cyanide, 0.211 lb. of lead acetate, 35.5 lb. of lime, 3.58 lb. of tube-mill pebbles, and 0.98 lb. of zinc-dust per ton of ore treated (323 tons daily).

FIVE HUNDRED AND TWO FEET of advance in one month was made last January in the Tiger adit (8 by 9 ft.) of the Burma Mines Corporation by Chinese miners, under white shift-bosses, using three Layner-Jugersoll drills at the face and mule traction up to a length of 6000 ft. The rock is rhyolite.

MANGANESE STEEL, as the term is used commercially, is a hard, tough, ductile steel. But sudden cooling from a heated condition is apt to make this steel too ductile, while slow cooling makes it brittle. It is used for such purposes as parts for rock-crushers and dredges, but is not suitable for the largest castings. The proportion of manganese is about 12%, with carbon 1½%.

ELECTRIC HOISTS of two types are used by the Cleveland-Cliffs Iron Co. They are the direct-current hoist operated by the Igner system, and the induction-motor-driven hoist. Induction motors, directly geared to the hoist, are used where the ore can be hoisted in loads as small as three tons, at a speed as low as 1000 ft. per minute. Where a greater product is required, the Igner system is employed. With a larger generating-station, however, greater induction motors could be used. It is

stated that in designing hoists for electric drive it is desirable to make the rope speed as low as possible, rather increasing the weight of the live load as necessary, than going to high speeds with light loads.

LEACHING TAILING at the Calumet & Hecla will be in operation during July. The process involves the use of ammonia supplied by the Semet-Solvay company of Syracuse, which makes the liquor from by-product coke manufacture. Two thousand tons of tailing is to be treated daily, the cycle of operations to occupy 96 hours. Eight vats 54 ft. diam. by 12 ft. high, holding 1000 tons each, are part of the plant.

STRONGER DETONATORS than formerly are being used, because the slight extra cost is many times repaid by the better explosion obtained in the charge. Suppose, for instance, that three sticks of powder in a hole are fired by a weak detonator, No. 3. The detonator will undoubtedly cause sufficient impulse to explode the first stick. The explosion of this will be communicated to the second, and thence to the third, and the whole charge will apparently explode. Yet among the resultant gases, there can probably be detected fumes such as are caused when an explosive burns rather than entirely detonates. The miner speaks of the powder as having 'burnt.' If instead of a No. 3 detonator, a No. 8 were used, the initial impulse would be transmitted right to the extreme end of the charge, instead of being passed from cartridge to cartridge. When the explosion has to be passed from cartridge to cartridge, it is possible that toward the end of the charge the impulse is so diminished in force as not to create that instantaneous transformation which is necessary for the best result. Detonation in such a case approaches the nature of combustion, and unexploded sticks of dynamite may be left in the holes.

EUCALYPTUS is a genus of tree indigenous to Australia, and called there 'gum-trees,' by reason of their resinous leaves and fibrous bark. One species, *eucalyptus globulus*, or blue gum, was brought to California over 50 years ago, and it has also been introduced into southern Europe, northern Africa, India, and the islands of the Pacific. The eucalypti are rapid in growth, straight, with few branches, and generally reach a great height, as much as 500 ft. on the Dandenong range, in Victoria. An oil of camphoraceous odor is obtained by aqueous distillation of the leaves, and this has been used in the making of perfumes and varnish, as well as for the flotation process in metallurgical plants. In Australia, several species of the timber are employed extensively for mining purposes. The jarrah and karri are well liked for head-frames, mine-timbering, and for building mills. The wood is hard and heavy. Jarrah is nearly double the weight of Oregon pine, so that a disadvantage is found in paying freight for a long haul, and it is likely to be short-grained. The eucalyptus in California has not as yet been used much for timber in mines, as other woods of lighter weight and less resin are available.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

LEADVILLE, COLORADO

ANOTHER LARGE DRAINAGE SCHEME.—EMPIRE ZINC AND WESTERN COMPANIES' PROGRESS.—DEVELOPMENT IN PROSPECT MOUNTAIN.—DOWN TOWN OPERATIONS.

What is considered to be the greatest mining venture ever undertaken in the Leadville district is now under way at the new Mikado shaft on Iron hill, as was briefly mentioned in the PRESS of June 24. George O. Argall, manager of the Iron Silver Mining Co., has organized one of the strongest combinations that have entered the district, and has secured control of a large tract of valuable territory extending through Graham park to Stray Horse gulch, and along the foot of Iron hill. The tract includes eight full claims; the R. A. M., Pyrenees, Devlin, and Cyclops of the Marion group, and the Sawtooth, Keystone, Venus, and Young America comprising the Mikado group.

Development of the property is to be carried on through the Mikado shaft, which is 1206 ft. deep. At present it is in poor condition, both inside and on the surface, requiring the installation of a new surface plant and re-timbering throughout the entire depth. Water stands at the 800-ft. mark in the shaft, making it necessary to install good machinery as soon as the shaft has been repaired to the water-level. Mr. Argall announces that he is prepared to fully equip the property with first-class machinery, and make all the necessary preparations in the shaft, an undertaking that is estimated to cost over \$300,000.

Construction work at the Mikado has been under way for two weeks under the direction of the contractor, Kenneth McLean. The largest head-frame in the district is being erected over the shaft. It is of four posts, 60 ft. high, with a 31 ft. base. It is being constructed of the best Oregon fir. The first and main bent of the frame has been hoisted into position; the work of assembling the secondary bent and supports is progressing rapidly. The completed frame will weigh more than 20 tons.

Expensive hoisting machinery has been ordered for installation as soon as construction work is finished. It is stated that the engine alone will cost \$10,000. Following the completion of the surface work, shaft timbering will begin. Several carloads of Oregon fir square-sets and lagging have been delivered at the property for this work.

Drainage of the working and the surrounding basin from the 800-ft. level to the bottom of the Mikado shaft will be the most difficult point of the undertaking. Many great old stopes in the sulphide zone exist throughout this area, and draining will be comparatively slow. Excellent machinery has been ordered for the work. Sinking of the shaft an additional 100 ft. is also planned.

The ore-belt which is to be explored through the Mikado shaft is one of the most extensive in the district. Several years ago this was the productive centre of Leadville. At that time such properties as the Maid of Erin, Adams, Mahala, Robert Emmet, Wolfstone, R. A. M., and Greenback were operating below 1000-ft. depth, and were shipping a large quantity of lead-silver ore. The decrease in the value of silver and the low metal market which prevailed for several years following, caused these properties to suspend operations in the sulphides, and those that had no other ores were forced to close entirely. Many of these famous old mines have been

idle for years, and it is only the recent revival in the metal market that has opened another period of activity for them. The large orebodies formerly abandoned are now very valuable and should produce millions of dollars under a continuation of the present favorable conditions.

The Empire Zinc Co., which recently purchased the Robert Emmet and other properties from the Small-Hopes-Borcel Mining Co., has undertaken extensive work preparatory to developing the immense bodies of sulphide ore known to exist in its holdings. This territory adjoins the Mikado project on the north-west. The old McCormick shaft on the Result claim is being re-timbered and a new surface plant has been installed, while extensive work is being done through the Emmet shaft.

The Western Mining Co. is draining the Wolfstone shaft to the 1000-ft. level, planning to get into the sulphide ores again. The Greenback is also active again, and as soon as the water has been taken out of the property through the Mikado and Wolfstone, work will be done in the rich stope that has stood idle for a number of years.

All the preliminary work, with the exception of the Mikado, will be completed during the summer, and there is no doubt that the tonnage of the district will be doubly increased by the production from these properties. There are thousands of tons of valuable ore now opened and blocked-out in these properties, and the development that will be carried on at greater depth will uncover much additional ore.

The draining of the Down Town basin through the Penrose shaft is now complete to a depth of 875 ft., the lowest level

GEOLOGY OF THE DOWN TOWN AREA, LEADVILLE.

in the property. The unwatering of the Down Town section was started on May 8, 1915. At that time the water stood at a point just 230 ft. below the collar of the shaft. The water was drained from the property to the full depth of the shaft on June 14, 1916. Pumping has been done by two electric centrifugal sinking pumps of 1500 gal. capacity, and two relief pumps of the similar capacity.

Work is now under way preparing the bottom station for the installation of a 2000 gal. four-stage motor-driven centrifugal station pump recently delivered by the Providence Manufacturing Co., makers of all the pumps used at the property. The pump is a vertical machine, and requires greater height in the station than the old steam pumps that formerly were operated there. The new pump will be propelled by a 650-hp. motor, the largest that has even been in use at Leadville. The motor is a new type patented by the General Electric Co. in June of last year. The station machinery will be in place by the end of the coming month, and immediately following an extensive

mining campaign will be taken up in the upper workings of the property where immense bodies of carbonate of zinc and high-grade manganese and iron ores have been uncovered.

The most important discovery of ore made in the district since the early 80's has been made in the Valley adit in Prospect mountain, in charge of Warren F. Page. At a depth of 150 ft. below the adit level, as mentioned in the Press of July 1, an immense body of oxidized iron, containing good values in silver and manganese, has been opened. The ore is identical with that found in the first contact of Carbonate, Fryer, and Breece hills, and is regarded as conclusive evidence of the continuation of the regular Leadville formation into the vast and undeveloped area of Canterbury hill and Prospect mountain. The property is now being equipped with large ore-bins and necessary buildings for the handling of a large output. Electric power is available in the adit, and is used for hoisting at the interior shaft, a distance of 1700 ft. from the portal.

Prospect mountain, lying immediately north of Big Evans gulch and on the trend of the strong ore-shoots developed in Fryer, Breece, and Carbonate hills, comprises an area of unlimited possibilities that for years has been neglected. Mining men have long been convinced that the Leadville formations known south of the Big Evans to Iowa gulch did not exist north into Prospect mountain, and looked on this territory as absolutely barren. It has only been recently that attention was turned in that direction, due undoubtedly to the success of the Valley, Silver Spoon, and New Monarch properties in Big Evans gulch. Drill-holes driven from the lower workings of these mines into the mountain disclosed remarkable results. It is stated that one of these holes from the Valley cut 40 ft. of ore.

The driving of the Valley adit was immediately undertaken by Mr. Page following the drilling, and the finding of ore in the interior shaft is the result of several months' continuous work. It occurs in the blue lime and porphyry that form the first contact throughout the now developed sections of the Leadville district. Huge bodies of rich ore have been mined in this zone throughout Carbonate, Fryer, and Breece hills and there seems to be no doubt that deposits equally as extensive will now be uncovered in Prospect mountain. Deeper development will also open the continuation of these ore-shoots into the second contact.

The importance of the opening of this vast and new territory can hardly be estimated. Should the formations hold as great a store of wealth in Prospect mountain as they have in the other parts of the district, Leadville will enjoy a great 'comeback.'

OATMAN, ARIZONA

NOTES ON THE PRINCIPAL PROPERTIES.

The Oatman district continues to be the centre of attraction in the south-west. Etienne A. Ritter has made an extensive study of the area, and in commenting upon the conditions prevailing there considered that it will prove to be a great gold producer. James G. Ray has just completed a long geological survey of the Esperanza Mining Co.'s ground. This is the most complete investigation which has been made of any property in the district, and is an exhaustive study of the geology, petrology, and mineralogy of the southern section of the field. Mr. Ray's recommendations as to further mining of the property will be carried out as rapidly as possible.

Persistent rumor continues to the effect that a fine development has been made on the new 1100-ft. level of the Tom Reed. Officials of the company will not confirm or deny this report. Ellis Mallory has started preparing a complete geological map of the Tom Reed company's holdings. The annual report of the company for the year ending March 31, 1916, has just been issued. It shows that during the year 5718 ft. of work was done. There was 29,916 tons of ore milled, the average value being \$22.12. The extraction was 98.6%. The yield was \$661.

571, against an average of \$739,690 for the preceding seven years. Total production is \$5,833,702. Dividends paid during the past year amounted to \$163,720, or 18% on the par value of the outstanding shares. It was estimated that 11,000 tons of ore was blocked-out in stopes at the end of the year.

The Gold Ore continues to ship 30 tons per day to the Gold Road mill, the extraction being better than \$20 per ton. Development of new ore continues.

At the Big Jim 35 men are at work, and drifts are being driven in both directions on the vein on the 400 and the 485-ft. levels. The faces of the four drifts are said to be in ore averaging \$35, \$150, \$30, and \$100 per ton, respectively. The first two values are for the drifts at 400 ft, which have been carried in farther than those on the deeper level.

Developments in the Ivanhoe property are the centre of interest in Oatman. At a depth of 500 ft., and a distance of 395 ft. from the shaft, and after cutting through an intrusive dike of quartz-porphyry, the main vein, which was the objective, was cut. On June 27 it had been penetrated 27 ft. beyond the foot-wall, with no hanging wall in sight. The vein filling is quartz, with some calcite and adularia, considerably stained by limonite, and highly oxidized.

Steady work continues in the Arizona Tom Reed, both in shaft-sinking and in lateral work on the 400-ft. level from the Pioneer shaft. Development in the Pioneer property, adjoining, overshadows in interest the work in the Arizona Tom Reed property. The two companies are developing the same main vein systems, it is estimated that the strike of the ore-shoots being developed in the Pioneer carry them into the adjoining property, so development of the one is considered as development of both.

In the Boundary Cone, driving operations on the 750-ft. level have not yet reached the zone where the downward continuation of the ore-shoots opened at 550 ft. are to be expected. The formation is promising.

In the United Eastern, blocking-out ore continues. Concrete foundations for the 200-ton mill will soon be completed, after which actual erection of the mill will be rushed.

The Black Range is steadily driving in ore on the 300-ft. level. Gold content is spotted, above \$30 for a few feet, and then dropping to very low-grade material.

Although a number of companies that entered the Oatman district and commenced operations on a 'shoe-string' are in financial straits, and some of these operators are sending out pessimistic reports, optimism among those who entered the field prepared to withstand a long development siege is higher than ever. Mining activity, backed by ample funds, is greater than at any previous time.

It is reported that the head of the Burro Creek Electric Company, George A. Thayer, was at Oatman during the last week, seeking to get contracts from the larger companies and mills in this district. Mr. Thayer visited the managements of the Tom Reed, Big Jim, Gold Road, United Eastern, Oatman, Paramount, Arizona Tom Reed, Golconda, and Boundary Cone mines, and will visit some of the smaller properties as they get ready to use power. The company has received a permit from the Arizona Corporation Commission to sell power here. The Burro Creek company generates its power at Burro creek, about 65 miles away, and will build a line into Oatman, which is expected to be completed within the next 12 or 18 months.

The present rate for current here is from \$12.50 to \$14 per hp., but the rate quoted by Mr. Thayer will reduce this to about \$5 per hp.-month. This reduction of electric current will have a material effect in stimulating development in this centre.

There are 125 properties being worked in the Oatman district. In the Black Range mine, 5 miles south-east, 3 ft. of \$29 ore has been cut at 300 ft. depth. Another note on this property appears in the above column.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

The Alaskan mining industry will have a prosperous season in 1916, according to a statement by Alfred H. Brooks, of the U. S. Geological Survey, covering the operations during the first six months of the year. Copper mining will probably show the greatest advances. About 15 Alaska copper mines are now shipping ore, and developments are being pushed on others, indicating that they may become producers before the end of the year. The gold lode mines of Alaska will also make a larger production this year than last, but it is not now expected that the placer mining will show any marked increase. The shipment of antimony from Alaska continues, and some tungsten ores have already been shipped from the Fairbanks district.

JUNEAU

May yields of the mines on Douglas island were as follows:

	Alaska Mexican	Alaska Treadwell	Alaska United
Stamps dropping	120	540	300
Ore crushed, tons	16,667	82,082	44,338
Gold from all sources.....	\$17,228	\$135,396	\$82,691
Yield per ton	\$1.02	\$1.65	\$1.80
Operating expenses	\$24,347	\$96,420	\$70,643
Construction charges	\$3,542	\$17,255	\$11,020
Profit	\$20,278	\$200
Loss	\$10,833
Other income	\$3,730	\$11,290	\$3,730

ARKANSAS

BOONE COUNTY

The need of a custom mill at Harrison is felt considerably, as both carbonate and sulphide zinc ore are mined, which is dumped for future treatment.

CALIFORNIA

AMADOR COUNTY

(Special Correspondence.)—Unwatering of the old Eureka mine is progressing satisfactorily. About 130 ft. of the north shaft has already been drained, and the timbers repaired for 60 ft. The old timbers were found to be solid, and many of the sets would not have to be changed had it not been for the settling of the ground around the collar of the shaft, which caused the sets to move slightly out of place. A cooling-tower has recently been erected near the compressor-house for cooling and re-utilizing the water used in pipes as a water-jacket for the working parts of the large air-compressor. This contrivance is something new for Mother Lode mines, as heretofore the mines in this part have wasted the water, except where it could be utilized as battery water.

Sutter Creek, June 30.

BUTTE COUNTY

A large diamond was found in the Cherokee district last week by J. Hufford.

INYO COUNTY

At a point 800 ft. from the portal of its Buena Vista adit, the Cerro Gordo Mines Co. has picked up the lower extension of its orebody. It is 25 by 30 ft., with 115 ft. of backs. Some of the zinc-lead ore is high grade. Zinc ore shipments to Al-

toona, Kansas, are 40 tons daily. Lead ore will be dispatched soon. Copper ore has been opened in the Blue Jay claim. All machinery is motor driven. Recent improvements cost \$50,000. Gold-silver-lead-copper slag from past smelting (1869) is being

CERRO GORDO MINE, INYO COUNTY.

shipped at the rate of 60 tons per day. About 25,000 tons of this material is available at low cost. An aerial tram delivers ore, etc., to Keeler, 5000 ft. below, and 8 miles by road. A mill to \$250,000 is contemplated. J. C. Climo is superintendent, and Louis D. Gordon is general manager, in charge of 75 men.

NEVADA COUNTY

For the purpose of hauling ore to the Golden Gate mill from the Narrow Gauge railroad, a 900-ft. tramway is soon to be constructed. It is said that the Pacific Western Commercial Co. is to treat tungsten and other ore from its mines in other districts at this 30-ton mill.

As 30 miners employed at the Spenceville copper mine were not paid for several months they have gone on strike.

PLUMAS COUNTY

The Engels Copper Co., near Taylorsville, is paying an initial dividend of 12c. per share, equal to \$22,000, on July 20. Monthly distributions are to follow. Net earnings for the past 6 months were \$275,000. Of this, \$137,000 was set aside for development.

SAN BERNARDINO COUNTY

(Special Correspondence.)—On the California side of the Colorado river, around Vidal, there is growing activity. The Bendigo Mines Co. of Los Angeles, which has shipped 450 tons of gold-copper-silver ore netting \$45 per ton during the last few months, is preparing another lot. Several individual operators nearby are also preparing shipments of ore, which as a rule go to the Hayden smelter in Arizona. One notable find of high-grade silver-lead ore has been made in the district during the past week, while on another property an 8-ft. vein of copper-silver-gold ore has been opened, yielding ship- ping ore at several places on the surface.

On the Parker side of the Colorado river in Arizona mining activity is increasing, and so much ore is being shipped that

several interests are considering building a custom smelter on the Colorado river near Parker, where it may be reached by mine operators on both sides of the river.

Vidal, June 28.

SHASTA COUNTY

Regarding the electrolytic plant to be erected by the Mammoth Copper Co. at Kennett, the general manager, G. W. Metcalfe, states that the plant will cost \$350,000. There is 25,000 tons of bag-house dust to treat, and more is being caught each day the blast-furnaces run. One thousand horse-power will be required. The chief element of cost is electric power. The company will build the plant on Backbone creek, a mile above the smelter. The process was developed at Winthrop by the Bully Hill Copper Co., which has spent 8 years experimenting. The Mammoth Copper Co.'s chemists spent four months last winter and spring at Bully Hill elaborating the process, which is something almost entirely new. Twenty-three per cent of the bag-house dust is zinc. It contains also gold, silver, and copper, as well as cadmium, bismuth, and antimony. The plant when at work will give employment to 50 or 60 men.

On Boulder creek, four miles west of Gibson, chrome and molybdenite deposits are being mined, 30 and 10 men, respectively, being employed. A car of chrome ore is to be shipped twice a week.

At French Gulch, 30 stamps are crushing 100 tons daily at the Gladstone mine. Ore is extracted from below 1000 ft. depth.

COLORADO

BOULDER COUNTY

Work is being rushed on the new 100-ton Degge-Clark tungsten mill in Boulder canyon. It is hoped to have the plant ready by July 15. Crushers and rolls are part of the equipment. Mr. Degge has been purchasing ore right along. He says: "I have absolute confidence in tungsten, and am convinced that there will soon be a steady market at \$30 to \$50. I expect to be a constant buyer at the market price, and as independent producers it is to our interest to keep the price up, and we shall do all in our power to do so."

When leases on the Primos company's properties expire on July 1 they will be permitted to be renewed. Two hundred lessees will be benefited. Under the present Primos schedule, lessees are paid \$12 per unit for ore containing up to 44%, and 50c. additional for each additional 1% of tungstic acid up to 60%.

CHAFEE COUNTY

A copper-bearing sandstone, in the Badger Creek district, a few miles east of Salida, is attracting much attention. The formation has been seen for years, but never prospected. The Badger Creek Copper Syndicate (J. Hamilton, D. H. Craig, S. V. V. Zabriskie, and others), have shipped a carload of ore.

GUNNISON COUNTY

The Pittsburg mine in lower Russell gulch continues to be the largest producer of high-grade ore in the county. The vein shows persistence with depth. The Iron City mill recently treated 4 cords (36 tons) of ore for 16 tons of concentrate containing 1.62 oz. gold and 4.38 oz. silver. Two shipments of ore assayed 1.07 and 7.57 oz. gold, 8 and 10 oz. silver, and 7.35 and 7.59% copper.

In Leavenworth gulch the Bezanet mine has a good streak of pitchblende (radium ore) on the 160-ft. level. It is expected soon to cut the uranium belt. Some copper-iron ore, containing 10 oz. gold per ton, also occurs on this level.

IDAHO

BLAINE COUNTY

The Federal Mining & Smelting Co., which recently acquired the North Star-Triumph mines, near Hailey, has begun the erection of a 300-ton daily capacity concentrator at the prop-

erty, according to Frederick Burbidge of Wallace, general manager for the Federal company. The plant will be equipped with a flotation annex and electric separator, and is being designed and fitted especially for treatment of the North Star-Triumph ores.

LEMMING COUNTY

(Special Correspondence).—Development by hand has been discontinued at the Goldstone mine at Baker, and machine-drills are working in the lower workings, where it is expected that the upper ore-shoots will be cut. In the meantime the mill is being re-modeled. H. F. Riebling is manager.

Baker, June 23.

OWYHEE COUNTY

The well-known De Lamar mine near Silver City has been sold to J. B. Duncan, W. R. Heim, and others. The manager, E. V. Orford, has formally turned over the property to the new owners. The property will be worked under a leasing system.

SHOSHONE COUNTY (COEUR D'ALENE)

The sale of the Independent mine, near Kellogg, to P. Gearon and others for \$300,000, is considered one of the most important for some time. Machinery for 600-ft. depth has been ordered. A wide lode shows on the surface.

Thirty-six tons of ore, assaying 285 oz. of silver, and 9% lead, recently returned \$3001 net to the Big Creek Leasing Co. of Kellogg. Prospects for more rich ore are good.

Large reserves have been developed in the Federal company's Morning mine at Mullan, and the daily output is to be increased from 1000 to 1500 tons.

The Bunker Hill & Sullivan company, at Kellogg, which has a lease on the Alhambra mine, is erecting a mill of 25-ton capacity. The mine has been opened by three adits.

At the National copper mine there are 60 men employed. The mill is worked five days per week. Ore on the 1200-ft. level is of better grade than on the upper levels.

For the sum of \$111,200 the Nipsie Mining Co. has sold its property to the Interstate-Callahan company. The claims are north of the new owner's mine.

The Constitution Mining & Milling Co., of which Judge George Turner, former United States senator from Washington, is president, has decided to build a mill on its property, the Constitution group, near Kellogg. The plant will be of 100 tons' daily capacity, and will cost between \$30,000 and \$35,000. The Constitution ore is complex lead-silver-zinc, and for the last three months the management has been making tests to determine the best concentrator that would be required to treat the ore. A mill-site has already been selected 1000 ft. from the main workings, at a point where adequate water can be secured from Pine creek and a small tributary stream.

Pine Creek notes are as follows:

In the lower adit of the Douglas mine of the Anaconda company the ore-shoot is 3 ft. wide and 850 ft. long. The adit 170 ft. above is also in good ore. Average metal-contents are 28% zinc, 12% lead, and 8 oz. silver per ton. A hoist and compressor are to be installed for shaft-sinking.

The Highland-Surprise mill is crushing 40 tons daily, and is being doubled in capacity. There are 50 men employed.

Regular shipments of zinc ore are being dispatched from the Constitution.

The Star Antimony mine has yielded 25 to 30 tons of 55% antimony ore during the past few weeks. The mine is developing well. The Star ore is hand-jigged, there being three machines, two running steadily. Water for the jigs is supplied by pumping it from the creek 700 ft. below, through a 2-in. pipe. The hill is steep and the ore is delivered at the wagon-road on a go-devil. It is the plan of the company when No. 3 adit is extended under the present workings to make a raise to No. 2, when all the ore will be taken out through No. 3. A gravity tramway will then be constructed that will deliver the ore from that level to the wagon-road, and this will

meet the requirements until a fourth adit opens the property at the lowest practical depth. Fourteen men are employed, working three shifts.

Other properties on the Creek report encouraging results. Near the Star mine a post-office and store have been opened.

A 300-ton flotation annex will be working within 60 days at the Interstate-Callahan mill. It will treat concentrate and re-treat accumulated tailings. Mill feed averages 28% zinc and 6% lead. A very favorable ore contract has been made with smelters.

The Vienna-International Mining Co.'s lead mine on Placer creek, 6 miles from Wallace, closed since 1910, is to be reopened by F. C. Bailey and others of Spokane. R. Mack is superintendent.

MICHIGAN

THE COPPER COUNTRY

The Calumet & Hecla and subsidiaries are paying employees an additional bonus of 25c. per day.—Under certain conditions the Court has denied restraint of sale of the Tamarack, as asked by G. M. Hyams.

MISSOURI

JASPER COUNTY (JOPLIN)

The ore market last week was peculiar. Choice products were just as firm as in the previous week; intermediate grades were weaker and brought \$2 to \$3 per ton less; inferior grades were stronger and brought \$5 more than the previous week. The decline in spelter to 11.75c. helped bear the ore-market, which under ordinary conditions would have been strengthened through the fact that production was considerably curtailed by heavy rains, according to the *News Herald*. Calamine found a ready market at \$52.50, for 'jag' lots, up to \$55 for carload lots at Joplin, and \$65 for carload lots at Granby, basis of 40% metallic zinc. Lead ore was \$3.50 weaker per ton, selling for \$77.50. The Missouri-Kansas-Oklahoma output was 6040 tons of blende, 194 tons of calamine, and 1037 tons of lead, averaging \$78, \$53, and \$76 per ton, respectively. The total value was \$564,495.

The output for the first half of the present and past years is as follows, according to the *Globe*:

	1916	1915
Blende, pounds	349,724,764	226,472,350
Blende, value	\$16,842,369	\$9,221,951
Calamine, pounds	18,745,720	21,973,102
Calamine, value	\$698,408	\$462,469
Lead, pounds	54,119,082	40,420,100
Lead, value	\$2,422,349	\$1,025,982
Total value	\$19,963,126	\$10,710,502

MONTANA

LINCOLN COUNTY

According to E. G. Mellander of Libby, a San Francisco firm is to construct a dredging plant at a cost of \$410,000. Gravel is 22 ft. deep to bed-rock. A steam-shovel will load the gravel to a car, which is lifted and discharged to a 4 by 28-ft. revolving screen. The fine material passes through sluice-boxes, and the boulders go to the dump.

SILVERBOW COUNTY (BUTTE)

According to *The Anode*, published by the Anaconda company, conditions at the Washoe smelter are steadily improving. With the completion of improvements under way, copper conditions will be considerably exceeded in the near future. Two steam, oil-burning locomotives have been added to the local tramming and weighing department equipment. The men who are to handle these engines have taken the examination, and as soon as the large storage-tanks are completed the supply of fuel-oil will be ready and the new engines assigned to service on the hot-metal run. The addition of this power will greatly increase the efficiency of the local tramming depart-

ment. The new change-house, under construction near the oil-flotation plant, is nearing completion. It will be a model of convenience, fire-proof in every particular equipped with steel lockers, sanitary wash-bowls and shower-baths. The building is of brick, concrete, and steel construction. The light colored brick used—the product of tailing from the oil-flotation plant—are laid in dark-brown mortar with recessed joints, giving the building an artistic appearance. The research laboratory, also under construction, will soon be completed. This structure will be up-to-date in every particular, and will embody many new features in laboratory practice. There was a marked decrease in incapacitating accidents during the month of May. This may be attributed to the improved condition in a number of departments in which heavy construction work and other alterations have been completed. When the plant reaches normal working condition, the record already established for a low accident rate, no doubt, will be lowered materially from the present record.

At the 1600-ft. level of the Butte & London two 20 by 65-ft. stations have been cut. Two 1250-ft. cross-cuts are now to be driven to cut 20 veins running east from Anaconda hill.

NEVADA

CLARK COUNTY (GOODSPRINGS)

In the Goodsprings zinc-lead district there are now over 40 producers, averaging over 5000 tons per month, employing over 1000 men. The town is growing steadily.

ESMERALDA COUNTY (GOLDFIELD)

Daily shipments from the Jumbo Extension are 150 tons, averaging above \$30 per ton. Over a week's dispatches averaged \$42 per ton. Some lower grade dump ore has also been marketed. Development continues satisfactory.

HUMBOLDT COUNTY

Plans are completed and work begins at once on the enlargement of the Rochester Mines mill to 180 to 200 ton capacity. The announcement is made by L. A. Friedman, president and general manager. The additional equipment is made necessary by the increased ore reserves in the mine at Rochester.

A new mill, to cost in the neighborhood of \$100,000, is being planned for the near future by M. Bylesby & Co. of Chicago, purchasers of the Ragged Top tungsten claims, heretofore known as the Beeson property. They will receive custom ores. Headquarter offices are at Lovelock. During the 60 days the new owners have been working the property they have extracted and shipped 550 tons of ore. Thirty-five men are employed. The mill will be erected at Toulon on the Southern Pacific, an 11-mile haul.

According to J. Q. Brown, manager of the Nevada Valleys Power Co., the increase in use of electricity in the Lovelock valley and mining districts is 400% greater than a year ago.

A mill is probably to be erected by the Chicago-Nevada Tungsten Co. at Toulon on the Southern Pacific line, 20 miles south-west of Lovelock. The plant will be on the shore of Humboldt sink, the only available water-supply.

At National, of which little is heard nowadays, the National mine is producing gold regularly. Development on the Indian Valley claim adjoining is satisfactory; so is that at the No. 2. On the south end of the Auto Hill property Maney brothers are opening antimonial-silver ore. Mines at Buckskin are giving good results, but treatment facilities are lacking.

At a depth of 1650 ft. the main vein of the Silver-Tough Coalition has been cut in the Bird winze. The value across 18 in. is \$300 gold per ton.

LINCOLN COUNTY

The Comet district, out from Pioche, is attracting attention on account of its gold, silver, lead, and tungsten deposits. Lack of easy transportation militates against rapid work. A few trucks are to be used. The Silver-Comet company has a 100-ft. at work in charge of E. D. Smiley.

this tram could be used to advantage by the United States army.

UTAH

JUAN COUNTY

On account of the embargo of the smelters the Iron Blossom company at Tintic has 500 tons of ore tied-up in cars at Silver City.—The Eagle & Blue Bell can only send 50 tons daily to the smelter.—Steady work continues at the Gemini and Bullion Beck.

SALT LAKE COUNTY

Work is to commence during July on a 2500-ton leaching plant for the Utah Copper Co. The capacity will gradually be increased. About 40,000,000 tons of 1% ore is available for treatment. E. A. Wall has transferred his three-quarter interest in the Kangaroo claim at Bingham to the company in consideration of \$30,000. The ground will be used for dumping purposes. It was originally the basis of a big damage suit, and the transfer settles the litigation between Wall and Utah Copper that has been waged for years. The company's mills are now treating over 30,000 tons of ore daily, with a copper yield at the rate of 17,000,000 lb. per month.

Development in the South Hecla, in the Little Cottonwood, continues good. Shipments last week were 300 tons averaging \$25 to \$30 per ton.

Driving of the 4000-ft. 7 by 9-ft. drainage and transportation adit by the Wasatch Mines Co. in Little Cottonwood has been started. Two 480-cu. ft. I-R. compressors will supply air. Exploration of a large area will be facilitated by this work.

On June 20 the Utah Copper Co. loaded 41,800 tons of ore at the mine at Bingham, a record. The daily tonnage treated in June is approximately 34,000. It is said that plans are to be prepared to increase the mills to 50,000 tons per day.

SUMMIT COUNTY

The Big Four Exploration Co. at Park City has over 100 men on additions to its tailing plant, which is being enlarged to 750 tons per day. A steam-shovel has been ordered to facilitate handling the tailing.

Sub-lessees at the American Flag mine are extracting \$40.91 gold-silver ore from the 500 and 700-ft. levels. Some ore contains up to 40.5% lead. The Park City Mines Co. is the lessee.

WASHINGTON

For the first 6 months of 1916 the mines of Washington promised increased production in the five important metals for the year. The industry generally seems to be in better condition than for several years past.

FERRY COUNTY

(Special Correspondence.)—The Republic Consolidated Mines Corporation is employing 40 men in the Lone Pine mine, shipping 200 tons of good ore per week. The company proposes to extend a drive into the Pearl ground on the Pearl-Surprise vein.—The Knob Hill mine is yielding 100 tons of ore per week, with five machine-drills and 20 men. A new compressor has been installed in place of the old one, recently damaged by fire.—The San Poil mine is employing 22 men on the first and second levels, and dropping the ore to the adit-level for exit to the shipping bins. The company is planning to sink the main shaft deeper.—Work has been temporarily suspended in the adit on the Copper Butte mine, Orient district, because of trouble with the compressor.—The Laurier Mining Co., Orient district, proposes driving an adit for lower working and cheaper ore extraction. The mine is producing and shipping a good grade of copper ore.

It is reported that the miners of Republic will strike for \$4 per day, in place of \$3.50, as now paid. On June 22 the Republic Mine Operators' Association was organized, with S. H. Richardson as chairman and D. M. Drumheller as secretary. There are between 110 and 125 men employed.

Republic, June 24.

PERSONAL

Note: The Editor is not responsible for the accuracy of the work and appointments of persons mentioned in the text.

GEORGE W. PEIRCE is at New York.

T. W. GRUTTER is at the Empire hotel, San Francisco.

C. B. LAKENAN is here from Ely, Nevada.

H. C. PERKINS and HENRY JENNINGS are at Treadwell, Alaska.

EDWIN E. CHASE and son have gone from Denver to Butte for two weeks.

WILLIAM MOTHERWELL has returned to Colorado Springs from Pachuca, Mexico.

ROBERT A. KINZIE has gone to Juneau and will be in that region for about six weeks.

GLENN L. ALLEN passed through San Francisco on his way from Salt Lake City to Bisbee.

SAMUEL FISCHER has been appointed assistant foreman at the Great Falls smelter of the Anaconda company.

GEORGE E. FARISH, of New York, has moved his western office from Denver to the Nevada Bank Bldg., San Francisco.

VALERIUS MCNUTT & HUGHES, petroleum and mining geologists, have moved their Oklahoma office to the Mayo building, at Tulsa.

VICTOR C. ALDERSON, formerly president of the Colorado School of Mines at Golden, was recently in the Winnemucca district, Nevada.

E. W. BULLARD, safety engineer of San Francisco, is spending two months studying the manufacture and use of safety equipment in the Eastern mining districts.

MALCOLM MACLAREN is now returning to London by way of Siberia, having completed his geological investigations in Korea. He is due in London about the middle of July.

N. C. WHITTEK, foreman in the oil-flotation plant at Great Falls, Montana, has resigned his position to go to Peru, where he will be connected with the Cerro de Pasco Copper Company.

CARL J. TRAUERMAN has resigned the position of mill-superintendent to the August Mining Co., at Landusky, Montana, and is inspecting the Beaver Creek mines at Zortman, in Montana.

BERNARD MACDONALD has moved his office from Los Angeles to the Mills building, El Paso. With the Alvarado Mining & Milling Co. he is designing an increase in capacity of its mill at Parral, Mexico.

THOMAS WOLFSON, vice-president of the United Metals Selling Co., and president of the Raritan Copper Works, Perth Amboy, New Jersey, was recently on a brief visit to Great Falls, Montana, for the first time in 27 years.

L. L. WITTICH, for several years correspondent of the Press and several other well-known journals for the Joplin district, Missouri, and mining editor of the *News Herald* at that centre, died on June 26 at the age of 34, leaving a wife and two children. Mr. Wittich was one of the best informed of writers on matters pertaining to the zinc region of south-west Missouri.

The American Institute of Electrical Engineers of New York with its 32 sections and 51 branches throughout the country, has a membership of 8212. This is a net increase of 158 during the year ended April 30, 1916. The revenue was \$111,199, and expenditure \$109,999. The surplus is \$614,913. John J. Carty is president. The Institute has its quarters with other engineering societies in the United Engineering building, New York, and with them is aiding the Government in its national preparedness scheme.

THE METAL MARKET

METAL PRICES

San Francisco, July 5.

Antimony, cents per pound.....	15
Electrolytic copper, cents per pound.....	29
Pig lead, cents per pound.....	7.25—8.25
Platinum: soft metal, per ounce.....	\$75
Platinum: hard metal, 10% iridium, per ounce.....	\$79
Quicksilver: per flask of 75 lb.	\$80
Spelter, cents per pound.....	15
Tin, cents per pound.....	13
Zinc-dust, cents per pound.....	20

ORE PRICES

San Francisco, July 5.

Antimony: 50% product, per unit (17 or 20 lb.).....	\$1.00
Chrome: 40% and over, f.o.b. cars California, per ton.12.00—14.00	
Manganese: 50% product, f.o.b. cars California, ton.12.00—20.00	
Magnesian: crude, per ton.....	7.00—10.00
Molybdenum: 50% and over, per pound.....	0.60—1.15
Tungsten: 60% WO ₃ , per unit.....	25.00—35.00

New York, June 28.

Antimony: The nominal quotation is \$2 per unit, but there is little doing. It is reported that ocean-freight arrangements are more difficult to make, and that South American ore is not easily obtainable.

Tungsten: Inquiry is a little more brisk, and several small deals have been put through at \$30 to \$32 per unit, spot delivery. More business probably could be done were it not that the owners of the concentrate are holding for \$35 to \$40. It is expected that the market will be more active in July, when the makers of tool-steel and ferro-tungsten will seek their second-half requirements.

EASTERN METAL MARKET

(By wire from New York.)

July 5.—Copper is dull and unchanged; lead is steady but quiet; spelter is neglected.

Owing to a mistake, some of the June 24 prices were given for those of the issue of July 1; the averages for the latter have been corrected.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Advice from London states that China and Indian sales are the cause of weakness in silver, but from a statistical point of view the future is favorable.

A shipment of silver from San Francisco to China on June 28 was worth \$222,000, say 352,000 ounces.

Zinc ore at Joplin, Missouri, averaged \$78.12 per ton for 60c product during June. The range was from \$60 to \$90.

The reduction of 8c. per lb. on three of the New Jersey Zinc Co.'s brands, mentioned here last week, referred to oxide products. On July 10 the company pays 10c. and on August 10, 1c. dividends. Including these, the disbursements this year total \$52 per share, equal to \$18,200,000.

Eastern Metal Market

New York, June 28.

Copper continues dull, with second-hands making what market there is.

Zinc has continued to decline, and the trade is wondering when the present trend will be checked.

Lead had a better tone based on moderate export buying last week, but it has turned easier again. The present level of prices is dependent on renewed foreign buying.

Tin is lower, with the supply unusually large. Banca tin offerings at concessions have helped to upset the market.

Antimony shows no improvement, and its price is lower.

Aluminum is weaker by 1c., following a lighter demand.

With the urgent war buying past, and new buying for the belligerents conducted on a conservative basis, there are many reasons for considering that extremely abnormal war prices have gone for good. The question now is, at what point above normal levels will prices settle? In the metals, as in many other commodities, it is beginning to be realized that prices which are far in excess of values tend to strangle business. In steel-construction work, for instance, many ventures of an investment nature are being indefinitely postponed because between 2.50 and 3.50c. per lb. is asked for structural shapes. All building materials are proportionately high.

Export buying of steel and pig iron is a supporting phase of the situation, while the prospect of large Government purchases of steel is another. The strike of iron miners in the Lake Superior district is growing in proportions, and may have a serious effect on the ore market. There are also fears that the transportation facilities may be inadequate to carry the season's output.

COPPER

The market continues very dull and weak, with scarcely enough drift to show the exact level at which any considerable business might be done. Such prices as are quoted are those established by the offerings of second-hands. Electrolytic can be had today without difficulty at 26.50c. cash, New York. The purely nominal price of Lake is 27.25c. cash, but it is so neglected that one price is about as good as another. That the producers are not looking for business at reduced prices is evidenced by the fact that most of them are holding to 29.50 to 29.75c. for August, whereas second-hands would be glad to sell at 26.50 to 27c. The brass mills are shading their quotations for brass rods, indicating that they are catching-up on deliveries. Brass sheets are still difficult to procure inside of six or eight weeks. Copper sheets are easier to get than they were a few weeks ago, the price being 37.50c., and some of the mills are looking for future business. Of course, all have enough to keep them busily employed for many weeks to come. The foreign demand for finished brass and copper products is fair, but not to be compared with that of even a few weeks ago. The London quotation for electrolytic yesterday was £130. Exports, June 1 to 27, totaled 29,256 tons. In the first four months of this year the exports of brass products, such as bars, plates, etc., totaled 29,591 tons, against 11,281 tons in the same period of last year. The National Brass & Copper Tube Co., commenting on the market, in its house organ, *Copper Gossip*, says:

"Business in copper is on a much more moderate scale than a few weeks ago, and apathy regarding the situation, on the basis of current quotations, gives evidence of the change in tons. The diminishing rate of activity is not surprising, however, after the aggressive buying earlier in the year when considered in connection with the hesitation over the outlook. The enthusiasm that accompanied the remarkable buying movements of a few months ago has evaporated. There is

more conservatism in all quarters. The impression in influential circles is that the price advance has been over-done, and that a more normal market is necessary to impart confidence."

ZINC

The trend of prices continues downward, business is almost at a standstill, and authorities in the trade are frankly disappointed. A few weeks ago they thought the turn had come, when there was a little business during which prices advanced about 1/2c. Then quiet came again, and it has lasted without a break. The New York quotation yesterday was about 11.75c. for spot zinc, with St. Louis around 11.50c., but it is reported that at least one sale of a round lot was made at 11.37 1/2c., St. Louis. July can be had at about 11c., New York, and August at 10.50c. Students of the market do not believe that the bottom has yet been reached. They hold that the trade should be satisfied if the market steadied at or near the existing levels, provided buying became active. It is notable that the premium for brass-mill special has about disappeared and that it can be had at very near the quotation for prime Western. If the decline can be checked, good buying by the sheet galvanizers probably will ensue. Exports keep up fairly well, those of the month, including June 27, amounting to 4078 tons; but they are not sufficient to absorb enough of our output at the present time. In Great Britain, consumption is being cut down by the shortage of labor, while another influence detrimental to our producers is the sale abroad of Japanese spelter. The output of Japan is reported to have been considerably increased, and that of France also. Despite the disposition of the British government to assist smelting in England it is hampered by the difficulty of getting ore from Australia. In France, large quantities of prime Western, purchased in the United States, has been re-refined for brass purposes. The London quotation for spot yesterday was £65.

Sheet zinc is quoted at 18c., f.o.b. smelter, carload lots.

LEAD

The crux of the lead situation lies in the export demand. If it is good, quotations here probably will be maintained, but if it becomes light, prices almost to a certainty will decline. About the middle of last week several thousand tons were taken by foreign buyers and the market stiffened a little, rising from 6.62c., New York, to 6.85c., but after the activity tapered off the market weakened again, and yesterday independents were eager for business at 6.80c., New York, and 6.65c., St. Louis. The A. S. & R. Co., meanwhile adheres to 7c., New York, and 6.92 1/2c., St. Louis. The London spot quotation yesterday was £29 15s. Existing demand runs chiefly to desilvered lead, said to be superior for some munition's purposes.

TIN

The market is weak and unsettled, partly because of the offerings of Banca tin at concessions of 1 to 1c. from the price for Straits, and because of the large arrivals. From June 1 to 27 these aggregated 5420 tons, with 2237 tons about. Fine deliveries into consumption promise to be large. There has been some quiet buying of futures by consumers, but not a great deal, and no real activity is expected until the market becomes steady. Spot Straits was quoted at New York yesterday at 39 cents.

ANTIMONY

Conditions are but little changed, and the market continues dull and listless. Lots of 5 to 10 tons can be had at 17.50c., with about 18c. asked for smaller quantities. Competition is so keen that the situation is in the buyers' hands.

Scrap Metals Recovered in 1915

The value of the copper, lead, zinc, tin, aluminum, and antimony recovered in the United States from scrap metals, skimmings, and drosses in 1915 was \$114,304,930, against \$57,039,706 in 1914, a 100% increase. The incentive of high

STRIPPING THE COPPER CORNICES OFF A BUILDING AT BERLIN.
(Copyright, International Film Service, Incorporated.)

prices caused all metal wastes to be more carefully saved, segregated, and refined. The output of secondary metals was as follows: copper, including brass and alloys, 196,000 tons; lead, 79,000 tons; zinc, 92,575 tons; tin, 12,447 tons; antimony, 3102 tons; and aluminum, 8500 tons, all large increases over the recovery in 1911.

Manganese in 1915

Production of manganese ore in the United States in 1915 was 9651 long tons, the largest since 1901, and more than three times the production in 1914, which was 2635 tons. This output was made by 31 operators in 10 States, of which the four most important, in order of output, were Georgia, California, Virginia, and Arkansas, according to figures compiled by the U. S. Geological Survey. In addition, Alabama, Arizona, Colorado, Tennessee, Texas, and Utah produced small amounts of ore. Imports of manganese ore in 1915 were 313,985 tons, compared with 283,291 tons in 1914. Of the ore imported in 1915, 268,786 tons, or 85% of the total, came from Brazil—more than twice the quantity received from Brazil in any preceding year. Imports from India were 36,450 tons, or about one-fourth the average of the preceding 10 years. No ore was received from Russia.

The production of manganiferous iron and silver ores in 1915 was 798,404 tons, almost twice the output in 1914. Most of this ore was used in making high-manganese pig-iron, but a large quantity was used as a flux by lead smelters; 66,530 tons contained more than 15% manganese and a large part of this was used to make low-grade ferro-manganese.

The prices offered for manganese ore adapted to the manufacture of ferro-manganese rose during 1915 to the highest figures that have been recorded for 30 years. In August, Eastern alloy makers offered \$22.50 per ton for 50% ore, compared with \$12.50 per ton, the average price for the preceding five years. In March, 1916, it was reported that \$32.50 per ton was paid for such ore. This great rise in prices was due largely to the advance in ocean freights caused by the shortage of vessels in which to move imported ore. There is good reason for expecting a further increase in domestic production during 1916 as a result of the high prices offered, but it is doubtful whether more than 10% of the domestic demand can be met by domestic production.

The shortage of high-grade manganese di-oxide ores caused by cessation of exports from Russia has become a serious menace to the dry battery and flint-glass industries. Prices as high as \$85 per ton are freely offered, but as only a few deposits in the United States can supply ore of this grade, little domestic ore has come to the market. There is record of a marketed production of 550 tons from mines in Arizona, California, Colorado, Utah, and Virginia during 1915, whereas the annual demand ranges from 20,000 to 25,000 tons. Ore of this grade was imported from Japan and Cuba during 1915.

Gold and Silver Production in the United States

The Bureau of the Mint and the Geological Survey have issued the following joint statement as to the final figures on the production of gold and silver in the United States during the calendar year 1915:

	Gold		Silver	
	Fine Oz.	Value	Fine Oz.	Value
Alabama	247	\$5,100		
Alaska	808,346	16,710,000	1,054,634	\$526,100
Arizona	220,392	4,555,900	5,665,672	2,826,500
California	1,090,731	22,547,400	1,689,924	843,100
Colorado	1,089,928	22,530,800	7,199,745	3,591,900
Georgia	1,684	34,800	141	100
Idaho	56,628	1,170,600	13,042,466	6,506,800
Illinois			3,892	1,900
Michigan			581,874	290,300
Missouri			55,534	27,700
Montana	240,825	4,978,300	14,423,173	7,195,600
Nevada	574,874	11,883,700	14,453,085	7,210,500
New Mexico	70,632	1,460,100	2,387,064	1,165,900
North Carolina	8,258	170,700	1,496	700
Oregon	90,321	1,867,100	125,499	62,600
Philippine Islands	63,898	1,320,900	15,148	7,600
Porto Rico	34	700		
South Carolina	174	3,600		
South Dakota	358,145	7,403,500	197,569	98,600
Tennessee	329	6,800	99,171	49,500
Texas	87	1,800	724,580	361,500
Utah	189,045	3,907,900	13,073,471	6,522,200
Vermont			150	100
Virginia	24	500		
Washington	22,330	461,600	213,877	106,700
Wyoming	672	13,900	2,910	1,400

Total 4,887,604 \$101,035,700 74,961,075 \$37,397,300

At the average price of silver per fine ounce for the calendar year 1915, \$0.49889.

These figures compare with the production of 1914—\$94,531,800 in gold and 72,455,100 fine ounces of silver.

The mill capacity was increased from 3000 to 4000 tons per month by adding a 6-ft. Hardinge ball-mill, in place of a 4-ft. machine. The plant treated 35,999 tons, averaging \$7.51 per ton. There was extracted 11,979 oz. gold and 1455 oz. silver, with 92.4% recovery. All costs amounted to \$5.47 per ton, a reduction of 97 cents. The net profit was \$196,919.

BOOK REVIEWS

ENGLISH AND AMERICAN TOOL BUILDERS. By Joseph Wickham Roe. P. 315. Index. Yale University Press, New Haven, Conn. For sale by MINING AND SCIENTIFIC PRESS, San Francisco. Price, \$3.

This is a historical work, dealing especially with the careers of the great builders of tools. It is a presentation of the human side of the evolution of machine-tool design and construction, and cannot fail to interest members of the engineering profession who can appreciate the human as well as the materialistic side of their work. The European War has created an immense demand for machine-tools of every description.

CARTRIDGE MANUFACTURE. By Douglas T. Hamilton. P. 167. Index. The Industrial Press, New York. For sale by MINING AND SCIENTIFIC PRESS, San Francisco. Price, \$1.50.

SHELL MANUFACTURE. By Douglas T. Hamilton. P. 296. Index. The Industrial Press, New York. For sale by MINING AND SCIENTIFIC PRESS, San Francisco. Price, \$2.50.

The War has brought about what might be termed an industrial upheaval in the United States. The demands made upon the American manufacturer by the belligerents in Europe for munitions of all kinds in quantities beyond precedent have practically created in the United States a new industry over night. The manufacture of cartridges and other munitions is a highly specialized industry, calling for the use of special tools and jigs not ordinarily applicable to other lines of manufacture. The publication of Mr. Hamilton's works is especially appropriate since the American government seems fairly committed at this time toward a policy of preparedness. The engineering-society work in the preparation of an industrial census should make every manufacturer of iron and steel products in the United States interested in learning how he may adapt his own equipment to munition-manufacturing in case of emergency. These works are up to the minute and go thoroughly into detail in regard to all of the requirements incident to the manufacture of cartridges and shrapnel and should find a place in the reference library of every machine shop operator.

MODERN STARTING, LIGHTING, AND IGNITION SYSTEMS. By Victor W. Page. P. 509. Ill., index. Norman W. Henley Publishing Co., New York. For sale by MINING AND SCIENTIFIC PRESS, San Francisco. Price, \$1.25.

The strides that have been made in the development of the mechanical details of motor cars have been so phenomenal that it is difficult even now to say whether or no the last word has been said on the subject of starting, lighting, and ignition. Nevertheless, the opinion is general that these phases of automobile design have been fairly well standardized. It is a far cry from the simple coil and battery ignition that was one of the chief causes of perplexity for the pioneer motorist of a few years ago, to the nearly 100%-reliable lighting, ignition, and starting units in use almost universally on the motor car of today, regardless of price. The automobile has proved to be a great educator to the layman, insofar as the operation of the motor, transmission, and differential are concerned, but the electric features still remain to a greater or less extent, a sealed book to the average motorist. Here, then, is an opportunity for those interested to understand the why and the wherefore of the electrical section of the automobile power-plant, an opportunity that should be taken advantage of by every motorist. The book is well written, in such a way as to be readily understandable by the average man. It is replete with illustrations that will facilitate a ready understanding of the text.

MINING DECISIONS

QUARRY LEASE—ABANDONMENT

A 99-years lease of a granite quarry required an annual rental, not to exceed \$25 when the quarry was worked, and a nominal rental of \$1 per year when the quarry was not worked. The lessees failed to work it for 14 years, and then after a dispute with the lessor persisted in their refusal to work it for an additional three years. Held, this inaction on the part of the lessees constituted an abandonment of the lease entitling the lessor to cancel it in a suit to quiet title.

Ellis v. Swan (Rhode Island), 96 Atlantic, 840. March 22, 1916.

PLACER LOCATIONS OF PHOSPHATE ROCK

The act of January 11, 1915, authorizing the completion under the placer mining laws of placer locations of lands containing deposits of phosphate rock, applies only to placer locations upon which the assessment work has been annually performed; and the Land Department is without authority to extend the remedial provisions of that act to locations upon which annual assessment work has not been performed.

San Francisco Chemical Co. (Land Department), 44 Land Decisions, 356. August 26, 1915.

EXTRA-LATERAL RIGHTS BELOW JUNCTION OF VEINS

The Supreme Court of Montana on re-hearing, modified its previous decision in the Anaconda Copper v. Pilot-Butte case by awarding to the plaintiff an extension of the temporary injunction theretofore granted, so as to include the portion of an extra-lateral right below the junction of a discovery and a secondary vein, which was properly tributary to the secondary vein. Previous decisions that as against a hostile claimant who owns no part of either apex, the boundary planes of the senior vein will control the right below the point of junction were affirmed.

Anaconda Copper Mining Co. v. Pilot-Butte Mining Co. (Montana), 156 Pacific 409. March 29, 1916.

BOUNDARIES—MONUMENTS—EXTRA-LATERAL RIGHTS

The general rule that monuments mentioned in a description of land prevail over courses and distances written in a conveyance thereof does not permit of the curtailment of the 1500 ft. of vein and 20.45 acres of a lode claim plainly called for in the patent, to a vein length of 1364.5 ft. and proportionately smaller area bounded by some stakes found 19 years after the patent was issued and not mentioned or described therein, there being no conflict between the courses and distances and the monuments named in the patent, and the posts in dispute being described solely in the field notes of the survey. The amendment of 1904 to Section 2327 Revised Statutes held not applicable to land patented prior to that date. Where a locator seeks protection of the provision of law giving him an extra-lateral right within side-end lines where he has by mistake located his claim across instead of along his vein, he must establish by a preponderance of evidence that the vein in question was actually the discovered vein and the location made in error. He will not be allowed after a lapse of 25 years after patent to claim an extra-lateral right through his end-lines on the basis of the newly discovered fact that there was a cross-vein apexing some 400 ft. away from the original discovery cut and that no length-wise veins exist.

Cookling Mining Co. v. Silver King Coalition Mining Co. (Utah), 230 Federal, 553. February 12, 1916.

EDITORIAL

T. A. RICKARD, Editor

CARRANZA'S credit is measured by the sale of an ice-cream cone for \$2 in fiat currency at the bridge spanning the Rio Grande between El Paso and Juarez.

THE index for volume 112, January to June 1916, is now ready, and may be obtained by writing to this office. The number 112 indicates that this paper has passed its 56th birthday.

FROM consular reports and other sources of information, it appears that the amount of American capital invested in Mexico makes a grand total of \$1,250,000,000, out of which \$225,000,000 is invested in mines, \$26,500,000 in smelters, and \$175,000,000 in the oil business.

"INVESTING American lives to recover American money" is what the *Evening Scream* calls intervention. But the fire-brigade risks life to save property and so does the policeman who attacks an armed burglar. Most of us think it honorable to protect our property and our rights.

SINCE 1890 the purchasing power of a dollar has decreased 37%, but the purchasing power of labor has not decreased in the same proportion. The rise in wages is the economic recognition of the higher cost of living, due not only to the enhanced price of necessities but also to the expanding consumption of luxuries.

WHAT will happen to the Mexican employees of the copper companies in the South-West in the event of war is a question rightly asked at this time. The population of the United States includes 120,000 Mexican men of adult age, of whom 10% only are naturalized. The opinion of the mine managers is that there is little probability of their Mexican employees returning to the country of their origin in order to take up arms against us, because they were never so well paid as they are now and the political tangle has diminished any natural patriotic impulse.

FEELINGS engendered by the horrors of the War have caused many thoughtful men to break from their mental moorings. We note with regret that Mr. Francis W. Hirst has had to resign the editorship of *The Economist*, in many respects the most trustworthy and influential financial paper in the world. He has used his position to express his personal convictions in regard to the great struggle and its baleful consequences to such an extent as to impair his efficiency in the more prosaic work of a commentator on commercial affairs. He was a fearless

and able editor, of a kind rare anywhere. To mining matters he gave much useful and incisive criticism. We hope he may find scope for his unusual ability and high character in some other post of duty.

LOW costs of producing copper are being spoiled by the hurry to take advantage of the abnormally favorable market. During the 15 months to April 1, 1916, the cost at Braden averaged 9.67 cents per pound, as against the estimate, made in January 1915, of 6½ cents. However, the profit per ton is the main item in mining, not the cost.

DISCUSSION this week starts with a thoughtful defence of the stamp-mill by Mr. W. E. Cahill, who writes from a locality where the stamp-mill is being used on an enormous scale. This letter may be read in conjunction with the editorial article on 'Rolls and Ball-Mills v. Stamps' appearing in our issue of October 16, 1915. Mr. Henry S. Reed writes feelingly on the subject of Sunday labor and voices the views, we believe, of many of our readers. We are always glad to give space to matters of human, as well as technical, interest.

CALIFORNIA has a great variety of useful minerals, but the value of them is not enhanced by such ignorant advertisement as is given in our local press. On the front page of a recent issue of the *Morning Herald* we find a lot of childish nonsense about a discovery of barytes, or barite, that is to yield "poisonous volcanic vapors" and "promises to become a menace to the Kaiser's armies fighting in Russia." And all because barite is a sulphate from which, it is stated, sulphuric acid is to be made. As a matter of fact the chief uses of the mineral are in the manufacture of paints, the coating of linoleums and oil-cloths, enameling iron and steel, besides adulterating sugar and making poker chips.

COPPER smelting and refining is being considered as the subject of taxation, says our Washington correspondent. The proposed Tariff Commission is expected to take the matter in hand, the impost suggested being 1% on annual receipts between \$25,000 and \$1,000,000; 2% up to \$10,000,000; and 3% on \$10,000,000 or more. Under such taxation, a number of companies would pay \$1 per share per annum and others from 50 to 80 cents per share, but this would be less than the daily fluctuation in the stock quotation and could hurt nobody. The Calumet & Hecla would pay \$5.50 per share, when copper sold at 25 cents per pound.

but even that should not break the heart of a patriotic Bostonian.

WHAT the zinc market owes to foreign trade is suggested by the statistics of export. During the first six months of the current year 108,500 tons of spelter was exported, as compared with 111,000 tons during the corresponding period of last year and only 1500 tons two years ago. What profits have accrued from the rise in spelter is indicated by the dividends paid by the New Jersey Zinc Company, which has distributed \$52 per \$100 share on its capital of \$35,000,000 during the past 8 months. One shareholder has received \$1,675.128 and another \$1,566.448 in dividends, while three others have each received over \$900,000 (one might call it a million for short!) during the same period, and among them we are glad to see the name of Mr. J. P. Wetherell, to whom the metallurgy of zinc is so largely indebted.

ANACONDA makes a fine showing in the report for the twelve months to June 1. The net profit is \$14,363,881 after expending \$8,715,881 on improvements. What these improvements are and how they have increased the efficiency of this splendid metallurgical establishment was made clear to our readers recently in the articles by Mr. L. S. Anstin and in our own comment. Owing to the fact that Anaconda does a large custom and refining business, it is not the company's habit to give information concerning the cost of operations. It has been estimated that the total cost is 10 cents per pound of copper. Mr. John D. Ryan has been quoted as saying that he could make copper for 5 cents per pound for 5 years if he cared to gut the mines, but his policy is exactly the opposite of that, namely, to operate the mines so that the enterprise will approach the character of an investment. It is probable that a cost of less than 9 cents per pound of copper will be attained when all the improvements have come into effect. The company's mines at Butte have penetrated below 3000 feet in vertical depth without noteworthy impoverishment.

EXPLORATION among old workings continues to be the main feature of mining at Leadville. The first enterprise of this kind, that of unwatering the Penrose shaft in the Down Town area, was completed in June, after 13 months of continuous pumping to a depth of 874 feet. The search for ore can now proceed. The next scheme was to unwater the Harvard shaft in the Fryer Hill district. This is being done by the United States Smelting, Refining & Exploration Company, a subsidiary of the well-known corporation having a nearly similar name. Then the Empire Zinc Company began to drain the Wolfstone shaft and its surrounding territory. In our last issue our Leadville correspondent gave many details concerning the latest venture, that of draining and re-opening a large area through the Mikado shaft, which is 1206 feet deep. This venture promises to be the most important. It is interesting to note that motor-driven centrifugal pumps are being used with great satisfaction. Sudden rushes of water and debris

from old openings cause 'burn-outs' occasionally, but these have proved minor interruptions. The high price of lead and of zinc, and lately of silver, gave an impulse to the re-opening of these old properties, and even though, as is confidently expected, extensive orebodies are uncovered, a further drop in prices will much disappoint those by whom capital has been subscribed for these plucky undertakings. Later in the current year we may expect to hear something about the first fruits of development in these abandoned portions of a famous mining district. The Valley adit, which penetrates Prospect mountain, another exploratory scheme, has disclosed iron-silver-manganese ore, and promises well. The Arkansas Valley smelter is crowded with ore, the Western zinc-oxide plant is being enlarged, and many promising undertakings are in full swing, so that the future of Leadville seems brighter than for a decade.

The Mexican Fizzle

On another page we publish a long and interesting letter by the mining engineer who was our correspondent in the City of Mexico. He, like other Americans, had to flee the country when Messrs. Wilson and Carranza began their exchange of explosive notes last month. We commend his description of the state of affairs prevailing in Mexico; it serves to indicate the ineptitude and corruption of the Carranza government. Mr. H. Lane Wilson, formerly ambassador to Mexico, is a man for whose judgment we have no particular respect, as we believe that he contributed largely to the mistaken policy of Mr. Taft, when President, but we note with approval a recent remark reported to have been made by him: "We recognized a *de facto* government that has since become a *de jure* government." And sufficient proof of it is to be found in the note from Washington on June 20, in which the Secretary of State asserts that for three years "American lives have been sacrificed, American enterprises destroyed"; there has been committed "outrage after outrage, atrocity after atrocity;" and during "attacks on American territory Carranza soldiers took part in the killing, looting, and burning." Yet, during all this time, knowing all these things, the Administration at the head of our government has recognized that of Carranza and his followers. Finally, they were called to order, the civilian soldiery of the United States was called to arms, and a show of real resentment was made. Carranza replied by issuing insulting statements at his own capital, for domestic consumption, meanwhile postponing a formal reply to the peremptory demands from Washington. He released the Carrizal prisoners without disavowing the orders to General Trevino that caused that affair of outposts. Before he replied to the note, the punitive expedition under General Pershing had been withdrawn nearly to the frontier, without having accomplished its object; for Villa is again on the rampage, as impudent as ever. Carranza appears to have scored, for the American threat has rallied Mexican support to his side and di-

verted attention momentarily from the grim reality of famine; Mr. Wilson's consistent desire to preserve peace has been varied by a sharp note and a little preparedness, neither apparently meant to be taken too seriously. So the crisis passes into a fizzle. Don Venustiano Carranza has made good his bluff. We are where we were; in that limbo of indecision called 'watchful waiting.' *Mañana* continues to epitomize the policy of the Administration. Again the relations of the United States and Mexico are in a state of flux; they drift on the logic of events, which is a current that flows just as decisively in a definite direction as the meanderings of the chief protagonists trend nowhere in particular. It is reported that the State Department will not hold itself responsible for the safety of any Americans remaining in Mexico. Is that to hold good indefinitely? If not, until when? Is the \$1,250,000,000 of American capital to be jettisoned until such time as Señor Carranza and his 'constitutional' friends restore order? Apparently, that is the idea; no chance of friction with those amiable gentlemen is to be risked by mentioning such little matters as the railways, oil-wells, and mines legally owned by Americans in Mexico. The United States has no moral right to interfere in a foreign country to defend its nationals resident there or the property they own there; so say the pacifists now dominant at Washington. The adventurer or concessionaire must take his chances; his country washes its hands of him. So? Yet we hear that the Administration is in consultation with New York bankers with a view to furnishing financial aid, that is, lending money, to the bankrupt government of Carranza. Is the loan to be protected by the United States or is it to share the fate of the equally honorable capital already expended in Mexico by mine operators, for example? What is the distinction? Of course, if any large sum is loaned by the banks, it will be on good security and that security will be the backing of the Government of the United States, and, what is more, the assurance that the Administration will take measures to protect the bankers' mortgage on Mexico. Meanwhile, the border will be patrolled by a large force, the boundary being 1300 miles long, with chances for complications continually present. Later, we shall have trouble with the European governments, when they have time to attend to this little affair, because they surely will not consent to the despoiling of their nationals, even if we are willing to see our own driven out of the country and dispossessed of their property. The problem will have to be faced; no 'watchful waiting' will solve it; it is a condition and not a theory that confronts us in Mexico, and no professorial philosophy can wave aside the brutal fact. The Mexican tangle can be made smooth in two ways: either the Carranza party will restore order and constitutional government, or the United States government will intervene, by consent or by force, for that purpose. No promise of either is evident. In the note of June 22 addressed to the representatives of the Central and South American republics, Mr. Lansing stated that even if hostilities ensued "this Government had for its object

not intervention in Mexican affairs but the defence of American territory from further invasion by bands of armed Mexicans, etc." Thus the Administration has pledged itself not to intervene, in the sense of helping or enforcing the restoration of order in Mexico. However, this pledge is not binding on the next Administration, and there lies the hope of ending this miserable farce. But whatever Mr. Wilson or Señor Carranza may do, or not do, one thing is certain: the 'rough house' in Mexico cannot endure. Our correspondent speaks of the spread of famine and of other factors that are bringing the country to utter misery and ruin. If we had a humane reason for going into Cuba—and we had it—we have many of them for going into Mexico. But apart from a condition that may be remedied, there is a greater force at work moulding the relations of the United States and Mexico. When President Roosevelt acquired the Panama Canal zone he flung the strategic frontier of the United States 1500 miles southward. To that latitude the United States will grow, not by annexation, let us hope, but by exercise of beneficent control. From the Great Lakes to the Panama Canal the United States is destined to exercise some sort of suzerainty. This fact must be faced by any man claiming to be a statesman, in the White House or at the National Palace.

Calumet & Hecla

On July 15 this great copper mining company celebrates its semi-centenary, having begun operations in 1866. The celebration arranged by the local management is meant to make the day memorable to the 5000 employed on the mine. Mr. Rodolphe L. Agassiz, president of the company and the son of Alexander Agassiz, the naturalist, who was superintendent of the mine in 1865, will share the honors with Mr. Timothy O'Shea, who has worked at the mine for 50 years and six months, having helped to dig the original pit excavated at the place of discovery. The actual discovery of the lode is to be credited to Edwin J. Hulbert, a local surveyor and a keen student of geology under such men as W. H. Stevens, Samuel W. Hill, and Charles Whittlesey. In 1858 he was surveying a State road from Copper Harbor to Ontonagon when he noticed a violent deflection of the magnetic needle in Section 23 (T. 56, R. 33), near where Hecla No. 1 shaft was sunk subsequently. He found fragments of a brecciated conglomerate containing native copper, resembling 'float' that he had seen several years earlier on the banks of the Eagle river. At this time he uncovered, on Section 14, an 'ancient' Indian pit, similar to others previously found on the Keweenaw peninsula. Upon examining the map he ascertained that the discovery was on Government land, whereupon, in February 1860, he acquired a tract of 1920 acres, so located as to cover the ground he intended to explore for the lode, not yet disclosed. The Civil War, his own illness, and other hindrances prevented him from doing anything until 1864. We have the testimony of the late James D. Hague, who was then manager of the Albany & Boston

mine in the same district, that Hulbert was convinced, by the behavior of the magnetic needle, that a strong lode existed in this part of the country. He even showed his note-book to Hague, indicating the most likely locality. A few months later the first exposure of the Calumet conglomerate was made, beneath a covering of soil and drift 8 feet thick, in a pit dug at a spot indicated by Hulbert himself. On September 17, 1864, his brother John and Amos H. Scott, working under his direction, cut through the amygdaloid forming the hanging wall of the lode, into the copper-bearing conglomerate on Section 13. A barrel of the ore was sent to Boston on November 15, 1864. Earlier in the same year, by aid of the late Horatio Bigelow, he had formed the Hulbert Mining Company for purposes of exploration. In this company he held a quarter interest, 5000 shares. In December the Calumet Mining Company, also with 20,000 shares, was organized to acquire the land in Section 13, and in the same month the Hecla company was formed, with another 20,000 shares. In the spring of 1865 he went to Boston, where he arranged with the late Quincy A. Shaw for the loan of \$16,800, wherewith to buy more land, which was deeded to the Calumet company. He received 5833 shares, making his holding 10,833 shares. Meanwhile the 'ancient' pit on Section 14 proved to be an Indian 'cache' or hiding-place, in which birch-bark baskets and a lot of oxidized copper was unearthed, but on sinking through the floor of this pit the lode itself was cut in February 1866. This was on ground belonging to the St. Mary's Mineral Land Company, and Hague endeavored to assist him in purchasing a large tract for \$100 per acre, but his friends in Boston thought the evidence of mineral wealth too scanty, so the deal was not made and Hulbert made his arrangements with Bigelow and Shaw. Section 23, a square mile or 640 acres, which became the Hecla property, was bought early in 1866 from the St. Mary's Mineral Land Company for \$60,000. The rest of the property, as then acquired, cost about \$100 per acre. Some of the first ore produced from the prospect-holes was milled at the Albany & Boston, where it yielded 14.5% 'mineral,' equivalent to 12% ingot copper.

It is fortunate that we have the testimony of such a scientific witness as James D. Hague on these historic events, besides the written record of the discoverer himself. Therefore there is no question that to Edwin J. Hulbert belongs the credit for the discovery of the Calumet & Hecla, and also for the exploratory work that led to the event. It may be added that the present writer was able to discuss the subject with Mr. Hague 12 years ago, and he also corresponded with Mr. Hulbert, at that time in retirement at Rome. In 1866, the shares of the Calumet company rose to \$75, but before the profit-making stage was reached there were many delays and much disappointment, causing financial embarrassment to Hulbert, among others. What with assessments and loans, about \$1,200,000 was required before the mine was placed firmly on its feet and in the interval the original owners of the enterprise were put to a severe

test. Hulbert lost a large part of his interest, becoming much embittered with Quincy Shaw and the Boston directors. In 1884, however, a settlement was made with him, whereby he received \$300,000 in Calumet & Hecla stock, which was placed in trust, so that he lived comfortably for the rest of his life.

The Hecla paid its first dividend, of \$5 per share, in December 1869; and the Calumet in August 1870. The two companies were consolidated in May 1871, absorbing the Portland and Scott companies at the same time. The Calumet & Hecla was then organized with a capital of \$1,000,000 in 40,000 shares. At that date (1871) the dividends of the united mines had already amounted to \$2,800,000. In 1874 the output was 230,000 tons yielding 4.28% copper at a cost of \$7.40 per ton of ore. In 1879 the capital stock was increased to \$2,500,000 in 100,000 shares of \$25 each, this being the limit allowed by the laws of Michigan. By 1881 eleven shafts had been sunk and an estate of 1720 acres had been consolidated. In 1883 the average width of stope was reported as 8 feet and the average yield 4.5% copper. The mine was then 3000 ft. deep on the dip, equivalent to 1950 feet vertical. In 1905 the charter of the company was amended so as to allow it to acquire control of other mines and organize subsidiary companies, whereby it now controls the Ahmeek, Allouez, Centennial, Osecola, Superior, and a number of other properties in the copper region of Michigan. These are now helping to redress the exhaustion of the original mine. The deepest shaft, the Red Jacket, is bottomed at a vertical depth of 4920 feet, cutting the lode at 3287 feet. As our readers know, the lode is cut on its dip in the adjoining Tamarack mine, in which the 'C. & H.' has a large interest. Up to date the company has paid \$130,750,000 in dividends, or \$1339 per share. The total production of copper is estimated at 1,342,500 tons. During the year 1915 the output of the Calumet & Hecla mine was 3,188,583 tons of ore yielding 71,030,518 pounds of copper, or 1.114%, at a cost of 9.33 cents per pound, as against an average price of 18.11 cents. The mine cost per ton of ore was \$1.71. During last year the company paid \$5,000,000 in dividends, drawing \$866,766 from its subsidiary companies. While the management was at one time both unprogressive and self-satisfied, it changed for the better about 15 years ago and is now highly respected, thanks measurably to Mr. James MacNaughton, the general manager, who was born at Calumet and has been in charge for nearly 20 years. Under its Boston control the mine has been worked as a source of copper and a legitimate investment, so that it escaped the stigma of chicanery that has marred the reputation of many other famous mines. To its proprietors, its employees, and the community around this big group of mines, the company has been a fruitful enterprise. Calumet & Hecla may be regarded as the most successful mine on record. We join in congratulating the directors, the management, and the staff, and hope that under its policy of sagacious expansion it may long continue to make a large contribution to the copper supply of the world.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Fine Grinding: Stamps and Ball-Mills

The Editor:

Sir—In your issue of May 13, Mr. Hanson's article contains the following statement: "At the mill of the Alaska Gold, at Juneau, a much more radical departure was made from what was considered standard practice in precious-metal ore-reduction. Here rolls and tube-mills, instead of stamps, were installed and this within hearing distance of the roar of the falling stamps at Treadwell. * * * This departure from conventional practice has probably done more toward sounding the death-knell to any future stamp installation on a large scale than any previous attempt to break away from standard method. * * * That this method of reduction is more economical both as to initial and operating costs than stamps alone, or than stamps when working jointly with tube-mills and grinding to a like fineness, can no longer be questioned."

It is well to ponder a moment. The stamps have served us so well that it is hardly fair to scrap them at one sweep. Granted that the initial cost of rolls and tubes is less than stamps, the stamp-mill has not been surpassed in economy to such an extent as to be unworthy of further consideration.

A point that is often overlooked is that the stamp-mill gives a finished product in one operation, whereas with rolls and tubes, etc., you will often hear of a certain machine handling an enormous tonnage at a very low cost, if you look a little further you will find that a lot of other machines are used to complete the job, so that in terms of finished product the cost per ton is something different. To make a comparison it is wise to consider the cost of the finished product.

Fortunately we have here, within the radius of a few miles, one mill, the Alaska Gold, using tubes and rolls; another, the experimental mill of the Alaska Juneau, using stamps as a primary crusher and finishing with Chilean mills; and last, but not least, the old stamps at Treadwell.

The actual cost, in operating, interest, and depreciation, for the mills at Treadwell during the year 1915 are as follows:

Mill	240		300		Ready
	stamps	stamps	Mexican	700-ft.	bullion
Crushing	\$0.038	\$0.038	\$0.040	\$0.037	\$0.022
Tramming	0.014	0.016	0.016	0.015	0.019
Stamping	0.211	0.189	0.192	0.170	0.182
Concentrating	0.066	0.059	0.058	0.052	0.070
Total	\$0.329	\$0.302	\$0.306	\$0.274	\$0.293

These data were kindly furnished by Mr. S. B. Combest, metallurgist for the Alaska Treadwell Company.

The comparative cost, as near as can be obtained, at the Alaska Gold is 33 cents. That of the Alaska Juneau experimental mill, using stamps as a primary crusher, is 32 cents per ton.

The Marcy mill with "one easy step" is looked upon favorably as a solution of the problem. This type of mill is to be installed at the Alaska Juneau and the results will be watched with great interest. The plans for consolidation and centralization at Treadwell include a new mill to replace the scattered units. What will it be?

W. E. CAHILL.

Treadwell, June 19.

Sunday Work at the Mine

The Editor:

Sir—I hope that Mr. F. C. Brown in your June 17 issue has started something, for this subject should provoke an interesting and instructive discussion. I am afraid, however, that the majority of men who turn to Trantwine or Rankin when in doubt will not so readily accept the authority quoted by Mr. Brown when it comes to mining and milling.

You know, it is a generally accepted idea that anything can be proved by the Scriptures. Paul says: "Prove all things. Hold fast that which is good," and I believe this thing is susceptible of actual proof. I have always been an advocate of Sunday closing of the mine, though I have never found a board of directors willing to put it to the test. Like many other things in this life, it depends upon the point from which the view is taken. A great many mines do shut-down on Sunday, but it is usually because the mill can be kept running seven days by six days work underground. There are few who will not admit that a man is a better workman for a weekly day off, except the poor unfortunate who comes back Monday morning chewing a dark-brown taste and feeling for his head at arm's length, and I respectfully submit that the one place in the world where a man of this class is not needed, be he mucker, miner, foreman, or superintendent, is underground, where the safety of all is so inter-dependent.

Whether the same be true of machinery or not, is another question, though many will state as a fact that it is. Certainly the mill that requires 52 days repair-work per annum is either poorly constructed or grossly neglected.

By far the majority of mining camps are isolated and their orebodies limited or uncertain, consequently there is little idea of permanency. Machinery merely to serve the purpose is installed; dwellings are cheap shacks put up without thought to sanitation or convenience, while culture of flower-gardens and trees would be the very last consideration; trails are used until road-building has become an absolute necessity. All this has developed a class of men unsettled in habits and ideas—here today and off tomorrow—packing a roll of blankets or at most a small cheap trunk.

Among the real reasons, as I see them, for running the mine on Sunday are inadequate development, storage capacity, or transportation facilities to meet the demands of the reduction plant. Pumping or ventilation might be necessary and a watchman might be a dead expense.

I believe the mill should be kept running every minute possible for 365½ days per year. Every hang-up, whether in amalgamation, cyanidation, or concentration means a loss not only of uncrushed ore but in the adjustment of pulp and solutions. It is not necessary to speak of blowing-in a smelter-furnace every Monday morning. The regular mill-crew or a part of them could lay off Sunday, their places being taken by substitutes who act as a reserve and are preparing themselves to become mill-men, getting their day on Saturday or Monday. But (and I emphasize the 'but') if we turn a camp-full of 25, 50, or 100 men out on Sunday who have been accustomed to work on that day, we must substitute something else, for it is a true saying that an idle brain is the devil's workshop. It makes no difference to the owner or manager how a man puts in his time; whether he goes to church or fishing, to a base-ball game or lolls about and engages in idle conversation, so long as he does not indulge in vicious practices that unfit him for his work; for, after all, it is not his time that he is selling to his employer, but what he can accomplish during that time. And this is where true management comes in. There are manifold possibilities in the club, the base-ball team, the camp-band and dances, athletic contests, beautifying of cottage grounds, the up-building of the idea of "our camp," but the management must avoid paternalism, for this is the one thing above all else that the American will not tolerate.

It requires tact and patience, but in time, by quiet elimination, a crew of men can be gathered who will gladly respond, and of whom any manager can be justly proud. I know one camp where before the end of the third day the new-comer would not think of coming to the dinner-table in his shirt-sleeves, and everything was quiet and orderly, even though the greater part of the men put their knives in their mouths. Needless to say, there were no flies in that dining-room, nor odors from the kitchen or swill-barrel. The superintendent had a tube built in the wall from his room to the dining-room down which he would occasionally send strains from his phonograph, and Saturday nights the tables and chairs were set back against the wall for a dance. I have not

yet seen a neater tidier camp with a more substantial mill and other buildings away back in difficult country far from the railroad nor known a superintendent who obtained more hard willing work from his men. Very few men were discharged and there were no drones. They eliminated themselves.

It might almost be said that each mine is in a class by itself, and that the rules applying to other camps and more especially to farming and manufacturing districts will not fit.

The underlying and commanding principle is one of time. The owner lives in the city and demands returns on his investment as soon as possible, realizing that all mines eventually, from their very nature, must cease to produce. I am willing, however, to believe that if he is shown that the betterment of the condition of his men will produce better men and better and more work, consequently profit, he will be equally willing to give the manager a chance to prove or disprove any theory. But the manager must believe in it himself and make more than ordinary effort. The mine owner will tell us that all our big men, our successful men, were and are workers, putting in long hours and continuous days. True and well. They are so constituted and have an object and pleasure in their work, an aim for their effort. I was reading an article just a few days ago in which it was stated in effect that only about 10% of us are successful anyway. Of course, that calls for a definition, and I modestly offer that success is the attainment of an individual's ideals, and it is the part of civilization to raise the standard of ideals.

So it resolves itself into a problem of sociology and not of religion, with perforce the dollar sign acting as a governor.

HENRY S. REED, JR.

Shawmut, Cal., June 22.

ARIZONA has a number of copper-mining companies, rivaling Michigan in that respect, and contrasting with the copper-mining industry in Montana, Utah, Nevada, Alaska, and New Mexico, where one or two large companies account for the bulk of the output. Of large mines Arizona has a full share. It is scarcely necessary to mention the Copper Queen and Calumet & Arizona at Bisbee, the Inspiration and Miami at Miami, the Ray Consolidated at Ray, the Old Dominion at Globe, the United Verde at Jerome, the Arizona Copper at Clifton, and the New Cornelia at Ajo. Among companies of more moderate size are the Shattuck-Arizona at Bisbee, the Consolidated Arizona at Humboldt, the Arizona Commercial and Iron Cap at Globe, the Shannon at Metcalf, the Detroit Copper at Morenci, the Ray-Hercules at Ray, the Magna at Superior, the United Verde Extension at Jerome, and several others less well known. The Shattuck-Arizona Copper Co., which produced 11,154,211 lb. of copper in 1915, makes occasional shipments of lead ore. The Magna Copper Co. produced 6,046,459 lb. of copper last year from 59,219 tons of ore, which is well over 100 lb. per ton.

Surficial Indications of Copper—IV

By Frank H. Probert

IN THIS article I shall digress somewhat from the sequence of thought followed in the three preceding contributions to the study of the forces, physical and chemical, that determine the nature of the outcrop. In the discussion of the chemistry of the oxidized zone, I explained briefly the nature of the surface solutions and the formation of the several important oxidized salts in the laboratory of the earth's crust. In the paragraphs that follow I shall first describe the duplication of Nature's work in the belt of leaching, as imitated by man in the treatment of the pyritic ores of Rio Tinto, and then compare the attractive gossan of the Huécula deposits with the insignificant outcrops of the Butte vein-system, interpolating such notes as are pertinent to the subject, gathered from other districts. I have visited and studied both the Spanish and Montana mining districts, but acknowledge, and have abstracted from, the lucid descriptions of A. M. Finlayson¹, and Reno Sales², respectively.

For many years pyritic ores from the open-cuts at Rio Tinto were piled into heaps, fired, roasted sweet, and then washed with water. The copper sulphate liquor was passed through precipitating-tanks and sponge-copper obtained. This process was costly, the sulphur was burned off, all vegetation killed for miles around, and endless trouble ensued. The 'natural cementation' process was developed from the chance observation of a colored liquor running from the base of an unroasted heap of ore, after a heavy summer rain. This contained copper. It was seen that roasting was unnecessary and that the time element could replace the effect of heat. This discovery led to systematic experimentation, the present method of treatment being devised about 25 years ago. I shall not dilate on the relative advantages of this method and the old wasteful practice of heap-roasting.

The ore from the pits is crushed in rock-breakers to 2½-inch ring, sized, and transported to the heaps. The ore, as laid down, contains about 2% copper, 52% sulphur, and 46% iron. The fine and coarse are mixed in varying proportions, according to the depth of the heap. At Rio Tinto, the ratio is 3 of fine to 7 of rough. When the heaps are too deep, the air will not circulate freely throughout the mass and the lower portions cannot be controlled. If not deep enough, aeration is too rapid, and the heap may take fire. Experience has shown that the most suitable depth is about 10 metres. The surface is covered with fine that serves as a filter for the wash-water. A simple irrigating system is arranged, the main canals feeding into furrows or shallow rectangular reser-

voirs so that water can be distributed to any part of the heap, as required.

The oxidation of pyrite is an exothermic reaction; heat is liberated and the mass will burn unless precautionary measures are taken to prevent it. Underground mine-fires are not at all uncommon in pyritic masses, owing to the heat generated in oxidation. At Jerome, Arizona, a special force of men is maintained to keep the fire-zones under control. When last at the United Verde, I noticed a crystalline sublimate on the timbers and walls of the openings near the fire-areas, which, on analysis, proved to be arsenic trioxide, 85% pure. This came from the arsenopyrite associated with the cupriferous sulphides. At the Coronado mine of the Arizona Copper Co., at Metcalf, when shrinkage stoping was first tried, a serious fire broke out and much valuable ore was lost. The trouble was in the size of the stopes. Peter B. Scotland, the mine manager, informs me that by working smaller stopes and drawing off the broken ore as quickly as possible, the danger of fire has been minimized.

Because of this tendency to burn, the temperature of the heaps at Rio Tinto has to be carefully regulated. It is found that the best results are obtained at about 120° F.

The washing of the heaps serves to keep the temperature down, forming ferrous sulphate and free acid, which react to form ferric sulphate. This attacks the copper sulphides, the resulting copper sulphate being leached out and carried away by the effluent liquor.

The amount of water used, per ton of ore treated, varies. At Tharsis it takes four cubic metres, half of which is required during the first year, one cubic metre for the second year, and one cubic metre to finish the leach. This quantity of water seems abnormal, but the spent liquor from the precipitating-plant is returned to the heaps to continue the work, so that the cycle is complete and the loss small. It takes about four years to extract all the copper. At both Rio Tinto and Tharsis, 50% of the copper in the ore as laid down is extracted in the first 12 months; 25% during the second year, and the remainder in the next two years, but at the end of the time, the pyrite is to all intents and purposes unaltered. Examined macroscopically, if the heaps have been properly regulated, it is difficult to distinguish between raw and leached ore, but the leached material has a more or less rusty appearance, due to films of iron oxide that have formed on inter-crystalline faces, and the mass is not quite so homogeneous. I have repeatedly observed that the periphery of pyritic orebodies, in the early stages of oxidation, presents this same appearance. On the 1000-ft. level of the Cole shaft of the Calumet & Arizona mine, at Bisbee, a cross-cut was run to the

¹Economic Geology, Vol. 5, pp. 403-434.

²Trans. A. I. M. E., Vol. 46, pp. 1555-1560.

Briggs shaft. It was in hard blue Devonian limestone, which, as an orebody was approached, became more blocky, the cleavages showed slight limonitic staining, and soon a mass of friable rusty pyrite was encountered, which ran like sand. When it was cleared, a partly oxidized orebody of cupriferous pyrite was opened up. The same condition was noted in the glory-hole and upper levels at the United Verde, but here there was an appreciable increase in the gold content. I have seen it at Butte, at Metcalf, and in surface exposure at a number of other mines. It is due to the leaching of the minute grains of chalcopyrite filling the inter-crystalline spaces of the pyrite. I consider it a favorable indicator either in surface exposure or underground development. It denotes the presence of cupriferous pyritic masses.

On looking over the leached heaps, I found that any lumps of chalcopyrite were but superficially altered. Fineness of division promotes chemical change. So, too, in outcrops or the upper workings of mines exploiting copper deposits, chalcopyrite is relatively resistant to the attack of oxygenated waters, whereas, when the two sulphides are associated, as cupriferous pyrite, the copper readily oxidizes. Possibly this is a catalytic reaction.

An analysis of the liquor leaving the heaps at Tharsis showed it to contain, at the time of my visit in 1900:

Copper	2103 grams per cubic metre.
Ferrous oxide.....	12252 grams per cubic metre.
Ferrie oxide.....	1710 grams per cubic metre.
Sulphuric acid.....	1297 grams per cubic metre.

At the Cerda plant of the Rio Tinto, the liquor contained 1445 grams of copper and 1570 grams of ferrie iron per cubic metre. As pig-iron is used to precipitate the copper, there would be an inordinate consumption of this material if the ferrie iron was not reduced before the liquors reached the precipitation-tanks. To effect this reduction, the liquors are made to filter through a small heap of fine material from richer ore. The ferrie salt is reduced to the ferrous stage with an increase of copper content, so that the liquor leaving the reducing beds contained 1583 grams copper and only 120 grams ferrie iron. This means a reduction of 1450 gm. of the persalt to the proto-salt—about 90%. I suggested, in my report to Phelps, Dodge & Co., for whom the investigation was made, the possibility of using a ferrie liquor obtained from the slow oxidation of a pyritic heap, for extracting copper from the low-grade oxide ores, of which they have such a large tonnage too low-grade to be worked profitably, in their mines at Morenci, Arizona. I subsequently conducted a series of tests along these lines, but had to record what Huxley termed a scientific tragedy, the killing of a beautiful theory by an ugly fact, for, try as I would, I could not get a sufficiently strong ferrie liquor by natural oxidation of the Morenci pyrite. Ferrie sulphide is slowly reduced by copper carbonates and oxides, and the copper dissolved, although sulphuric acid is a much more ready solvent. The Arizona Copper Co. leaches the tailing from the rough oxide-ore concentrator by sulphuric acid, at a substantial profit, and the same

solvent will be used at Ajo, Arizona, and at Chuquibambilla, in Chile.

It is probable that the free acid formed by the attack of oxygenated meteoric waters on sulphide minerals is the most potent factor in the early change of copper outcrops, and that as the supply of free air is diminished, the ferrie solutions become more and more active.

The rich blue liquor leaving the reducing beds at Rio Tinto is in striking contrast with the deep-green entering ferrie waters. The copper is precipitated in an elaborate series of tanks, aggregating about three kilometres in length, the inclination of which increases as the copper is precipitated. For the first 40% of the copper, it is 1 in 200; for the next 30%, 1 in 150; then 1 in 100, and for the last 10% of the copper, 1 in 50. For the first 80% of the copper, the tanks are 90 cm. deep, and for the rest of the run only 30 cm. If there is much ferrie iron or free acid in the liquors, they are by-passed to tanks of greater slope. This prevents the throwing down of arsenic, the tendency of which increases as the quantity of copper is lessened and free acid rises. The upper tanks precipitate the bulk of the copper, 60% being taken out in the first 700 metres. The spent liquors, leaving the tanks to be pumped back to the ore-heaps, show a complete reduction of the ferrie iron, and a neutralization of 600 gm. of free acid per cubic metre. Over 70% of the copper precipitate assays better than 94% copper.

The consumption of pig-iron at Tharsis is 1.25 lb. per unit of copper obtained.

I have described this natural cementation process not only because it presents many novel features, but because the reactions are the same as those that occur in the natural oxidation of ore deposits. Man substitutes heat for time, but Nature cannot be hurried. It may be questioned by my readers why the rich copper sulphate liquor does not precipitate or form enriched sulphide, such as chalcocite, when it passes through the so-called reducing beds. This apparent contradiction to the theory of chalcocitization is readily explained if we desist from thinking of laboratory conditions when discussing geological processes. At Rio Tinto, the success of the method depends on the aeration of the heaps and the maintenance of special conditions of temperature, porosity, and flooding with solutions under control. In the confines of the earth's crust, free air cannot enter to any extent, and totally different conditions exist.

The relative solubility and order of attack of the sulphide minerals has already been mentioned.³ The effect of the association of the natural sulphides on the rate of oxidation has also been explained.⁴ After four years oxidation and washing the iron pyrite of the Rio Tinto heaps is practically unaltered, but, geologically, four years is a negligible interval of time. The hematitic croppings of veins or masses are the result of the long-continued attack of chemical and physical forces.

The pyritic copper deposits of Huelva, Spain, occur as a series of lenticular masses, showing marked variation in

³M. & S. P., Vol. 112, p. 894.

⁴Op. cit., p. 895.

size, in a metallographic province extending for many miles from the province of Seville, westward into Portugal. Roughly speaking, these irregular masses of cupriferous pyrite are from 1000 to 2000 ft. long, 100 to 300 ft. wide, and of a depth consistent with the other two

orebody, others may apex with the little end up. An insignificant outcrop may represent either the top or bottom of a lens of ore. It is doubtful if many of the Huerva deposits would be known today had it not been for long-continued erosion. The orebodies are of deep-

INCIPIENT MINERALIZATION OF BUTTE GRANITE, 600-FT. LEVEL,
BERTHA MINE, CORBIN, MONTANA.

dimensions of a lenticular mass. Denudation or erosion has been the all-important factor in determining the present vertical extent of the orebodies now being worked, or such as are indicated at the surface by gossan outcrops. One lens may feather out a short distance below its outcrop, showing only the root of an eroded

orebody, others may apex with the little end up. An insignificant outcrop may represent either the top or bottom of a lens of ore. It is doubtful if many of the Huerva deposits would be known today had it not been for long-continued erosion. The orebodies are of deep-seated origin, formed during Permian-Carboniferous time. Of the 33 known deposits, 4 are enclosed in porphyry, 2 at the contact between slate and diabase, 11 at the contact of slate and porphyry, while 16 are wholly within the metamorphosed sedimentary rocks. They cannot be related genetically to any one group of igneous rocks. As I have already pointed out, an orebody may be, and often is, the result of cumulative processes of mineralization, the metallic emanations of one magma serving as a nucleus or locus of deposition for the heavy vapors from later intrusives. The wall-rocks are impregnated with pyrite, enriched in places to form workable deposits. The whole section of country has been repeatedly fractured and sheared,

but the pyritic masses themselves do not show extensive alteration on account of their massive and resistant nature. Imperfect jointing has, however, been developed.

As a result of careful microscopic work, Mr. Finlayson finds that the copper present in the ore is not chemically

OUTCROP OF QUARTZ-PYRITE VEIN IN ALTERED GRANITE, BUTTE, MONTANA. (Copied from Professional Paper No. 74, U. S. G. S.)

combined with the pyrite, and that secondary chalcopyrite followed by chalcocite in the narrow orebodies, and chalcocite in the lean deeper ores, is the evidence of enriching processes. He also states that the preliminary changes, due to enrichment, extend far down into what is usually regarded as primary ore. The unenriched ore is essentially a mechanical admixture of chalcopyrite and iron pyrite.

The oxidized zone or gossan consists of massive hematite containing over 50% iron. The average depth of it is about 100 ft. The depth of oxidation has been determined in all cases by the topographic level of groundwater. The width of the outcrop and the boldness of its exposure depend upon the plane in the vertical scale to which erosion has advanced. The ore is mined by open-pit methods. To anybody standing at the edge of one of these large pits, the colors of the several zones appear most vivid; the deep red of the capping contrasting strikingly with the pale bluish-green of the sulphides. Between the leached overburden and the pyritic ore, there is a ribbon, several inches wide, of bright ochreous-yellow material containing the concentrated precious metals of the oxidized zone.

This ribbon, carrying the concentrated precious metals, was formed by the precipitation of the dissolved gold and silver in oxygenated ferric sulphate solutions, as soon as the strongly reducing influence of the pyritic zone was reached. It is not a mechanical concentration, for the overburden of massive hematite, from 50 to 150 ft. deep, dependent on erosion, is very compact. This yellow layer will assay \$30 to \$40 per ton.

The upper zone of the enriched sulphides shows a slight impoverishment, and below this narrow belt the ore is richer in chalcocite, running as high as 6 and 7% copper. This gradually fades into the cupriferrous mass below. There is an abrupt change between the oxidized and enriched ore, but no sharp line of demarkation between the enriched and primary pyritic ore. The zone of transition is variable in extent, but the average depth of enrichment is from 150 to 200 ft. below the gossan or 250 to 350 ft. below the surface. To this depth the ore has averaged about 3%. The relation between the depth of enrichment and the depth of gossan is particularly well emphasized in this district. There is no appreciable quantity of copper salts in the oxidized capping. The chemical processes of cementation have proceeded faster than the physical forces of denudation. The rainfall, about 25 inches per annum, has been sufficient to ensure deep alteration, but insufficient to cause rapid erosion in a country of gentle slopes and smooth surfaces.

Mr. Finlayson summarizes his views concerning these deposits as follows:

1. The pyritic orebodies of the Huelva district constitute a metallo-genetic province accompanying a petrographic province; and the concentration of the ores has been due, in the first place, to a process of magmatic segregation of sulphides accompanying the differentiation of the igneous rocks, and dependent, with this latter, on the Hercynian tectonic movements.

2. The ores have been deposited from solutions that, after the cessation of the igneous outbursts, rose along great thrust-planes or shear-zones; and the deposit was effected by replacement of the sheared and crushed rock by the ores.

3. Since the formation of the lodes, great denudation, with accompanying sulphide enrichment (by descending waters) has taken place, and to this enrichment the economic importance of the deposits as a source of copper, and the leading position of this locality among the great copper districts, is very largely, if not entirely, due.

In Finlayson's comprehensive description of the pyritic deposits of Huelva, no mention is made of the influence on the alteration of the pyritic masses by a migratory water-level, nor am I able to find in the review of the literature of these deposits any comment on the relationship of structure to the oxidized zone. The absence of faults, shearing, or prominent joint-planes, or, in other words, the general compactness of the gossan, anticipates a slow and complete oxidation of the mass to a definite horizon and accounts for the abrupt change from the leached material to the enriched ore. There is unquestionable evidence of great tectonic movements later than the ore deposits, but these only find expression in the surrounding rock or at the lode-walls. I have already pointed out that structural details have a great influence on the depth of oxidation and on the enrichment of ore below. The slow and continued solution of the copper contained in the upper part of the Rio Tinto deposits probably accounts for the complete extraction of the copper, and the general distribution of the enriched ore along horizontal planes in gradually decreasing amount as depth is attained. This seems to be a general condition in all such pyritic masses that I have examined. At the United Verde mine, in Arizona, large pyritic masses have been explored, but none find surface expression. I noted there that, where the erratic bodies traversed by highly altered dioritic rock, along lines of structural weakness, the pyrite is locally enriched with secondary chalcopyrite. At the Copper Chief mine, a few miles from the United Verde, the outcrop of one of these pyritic orebodies shows as a loosely coherent, sandy, limonitic mass with little or no oxidized copper salts. Here, too, the zone of oxidation is limited by an approximately horizontal plane. Referring to the massive pyritic deposits of Ducktown, in Tennessee, W. H. Emmons says, "The secondary zone is less extensive vertically than most chalcocite zones elsewhere. The lodes are comparatively impervious to downward circulation, and it is believed that the reactions were brought nearly to completion before the descending oxidized solutions had moved downward great distances."

At Fierro, in New Mexico, the sudden change between oxidized capping, which is shipped by the Colorado Fuel & Iron Co. as an iron ore, and the lean, compact, underlying pyrite, is very noticeable. J. A. Reid has called attention to the effect of lateral pressure on the down-

ward passage of meteoric waters, and in this way explains the absence of a zone of enrichment in the Cop-peropolis deposits.⁶

J. W. Finch thus describes the La Reforma mine, in Guerrero, Mexico:⁷ "The topography is very rough, which pre-supposes rapid run-off. The orebodies consist of massive pyrite, chalcopyrite, and associated sulphides. An imperfect joint-structure has developed in the mass, but no openings that would admit of widespread percolation of meteoric waters. Such fracturing as there is, is apparently recent. The capping is of the usual gossan type, containing no copper, but gold, silver, and lead are concentrated above the pyrite zone. All the value of the oxidized zone is residual. The pyrite mass was saturated with water held there by capillarity between crystal faces, thus preventing the downward seepage of surface waters and consequent enrichment. Such copper as was leached from the gossan capping has been diverted laterally and escaped with the run-off. The line between the zones of oxidation and enrichment is as sharp as that between two surfaces."

While discussing pyritic masses, of which Rio Tinto is a type, it may interest my readers to know that these Spanish mines have been worked intermittently for over 2000 years. They were successfully operated by the Romans and by the Phœnicians before them. Siculus, writing of the Spanish mines in the first century B. C., says, "Sometimes at great depths they met great rivers underground, but by art gave check to the violence of the streams." "They admirably pumped out the water with those instruments called Egyptian pumps, invented by Archimedes. By these, with constant pumping on turns, they threw up the water to the mouth of the pit and thus drained the mine; for this engine is so ingeniously contrived that a vast quantity of water is strangely, and with little labor, cast out." "The re-opening of the mines at Rio Tinto in the middle of the eighteenth century disclosed old Roman stopes in which were found several water-wheels. These were about 15 ft. in diameter, lifting the water through a reverse arrangement to an overshot water-wheel. A wooden Archimedian screw was also found in the neighborhood."⁸

Enormous slag dumps, undoubtedly of Roman time, are still to be seen at Rio Tinto. They are bi-silicate slags, unaltered by weathering during this long interval of time, and on analysis I found them to contain less than 0.2% copper. Such metallurgical work we, with all our modern plant, can scarcely duplicate today. Several relics of the old Roman mining methods survive. Slave labor was used, and there is every reason to believe that 'high-grading' was practised just as much in those days as it is now. The miners would steal a handful of the yellow material found between the overburden and the ore and, having accumulated sufficient for a charge, would melt it down in small scorifying furnaces made of adobe. The yield was in the form of plaques running

98% silver. Several of these were found while I was in Spain, cached away in some old workings.

From Huelva to Butte is a far cry. The climatic conditions are totally dissimilar, the ore deposits are of two distinct types, the one is worked by open-cut mining and steam-shovels at comparatively shallow depths, the other

RIO TINTO. A BENCH IN THE MAKING AT THE EAST END OF THE SOUTH-COBE OPEN-CUT.

by shafts to depths of 3000 odd feet; in one the ore occurs as massive lenses, at the other in definite veins; at Rio Tinto faults have played a minor role in the enrichment and have not interfered with the ore lenses, at Butte all the veins are faulted and a most complicated structure results; the Rio Tinto deposits have most attractive surface showings, while the Butte outcrops are inconspicuous to the degree almost of non-existence.

The Butte district has been studied exhaustively. It has, probably, received more attention from competent geologists than any other copper district in the world. All agree as to the rock sequence and the complex structure, but there is no uniformity of ideas as to the age of the several ores found there. Under the direction of Reno Sales and his geological department, practically all of the exploratory work of the Anaconda Copper Co. is planned. The value of the services of the economic or mining geologist in directing mining work has been recognized and demonstrated in this field. On behalf of the U. S. Geological Survey, W. H. Weed investigated the district and presented his findings as Professional Paper No. 74. His unravelling of the fault-complex and deductions as to ore genesis served as a basis for the more complete investigation of Sales, the results of which were published in the Transactions of the A. I. M. E., Vol. 46, pp. 1523-1626. The later work of J. C. Ray called attention to the sequence of sulphides in the Butte ores.⁹

The Butte district, of which Anaconda hill is the centre, is made up almost entirely of a highly altered quartz-monzonite or 'granite,' as it is locally called, which is a part of the great Boulder batholith. The productive area is about $1\frac{1}{2}$ miles long and 1 mile wide, although many mines have been opened up in the same granite mass within a radius of 30 miles of Butte. Differential cooling of the granitic magma resulted in the intrusion of acid dikes of aplite, the economic significance of which is not apparent. Later acid intrusions of rhyolite have probably a genetic connection with the copper ores.

The copper output of Butte comes from vein mines. All the ore is confined to definite fractures; and while the granitic wall-rocks are pyritized, they are non-commercial. Several of the shafts have reached a depth of 3000 ft. and as yet there is no indication whatever of impoverishment.

Fissuring of the granite is a common feature throughout the batholith. In addition to the fissuring, profound faults of several periods of regional disturbance, both before and after vein formation or mineral deposition, have brought about a condition of intricate complexity, which has resulted in so much litigation. The fissures may be divided into six distinct systems, of which the Anaconda or east-west system is the oldest, as well as the most solidly and continuously mineralized. The oldest fault fissures in which ore is found constitute the Blue system. Extensive rock alteration has taken place, particularly in Anaconda hill. It is closely related to the important vein-systems. The alteration has affected both the country rock and the veins and faults. It is due to the effect of the early mineralizing solutions, to the influence of descending waters, and to natural oxidation. These processes overlap. The greatest change is noticed in the oldest, or Anaconda, vein-system. The faulting and crushing of the Butte granite has been on a profound scale, and both chemical and dynamic agencies have combined to bring about present conditions. The

granite is pyritized and nearly all the ferro-magnesian minerals are obliterated; the feldspars develop sericite and secondary silica. In the upper levels kaolinization is advanced owing to the action of sulphate waters upon the sericitized granite.

The effects of hydro-metamorphism are more noticeable where vein-forming influences have been most active, that is, in the zone associated with the Anaconda vein-system. The most marked effects are kaolinization and chalcocitization, accompanied by greater porosity. The average depth of the oxidized zone is 300 ft. in the highly altered area. While chalcocitization is always accompanied by kaolinization, the reverse does not hold good, and it is thought that sulphate waters have been active at depth, long after the last trace of their contained copper had been precipitated as chalcocite. A distinction between 'sooty' chalcocite of secondary origin and 'primary' chalcocite, which occurs in quantity, is important. The zone of secondary chalcocite varies from 50 to 200 ft. in the fault-veins to a maximum of 1200 ft. in the older veins of the Anaconda system.

It is probable that surface waters have caused changes in the rock-mass beyond the depth reached by mine-workings. On account of the structure, the ground-water level is very variable. Present ground-water, even where found at great depth, is of meteoric origin and contains appreciable quantities of free acid and the iron sulphates. Secondary enrichment in the Butte district is dependent largely on the topography and the mineralogic and physical characteristics of the vein in which the sulphides occur.

Ice planation, rock disintegration, erosion, and the Continental fault have determined the present surface contours and caused a mantle of wash to mask many of the intersections of the veins with the surface. Aside from this, the outcrops are indistinct and are seldom recognizable in the absence of shafts or pits. Butte has the least surface evidence of mineralization of any district I have studied. The highly colored oxidation products of copper minerals are conspicuous by their absence, and with the exception of local developments, no oxide ores are mined at Butte. Almost without exception, the copper veins are practically barren of copper at the outcrop and in the zone of oxidation. The outcrop of a typical vein of the Anaconda series is marked by altered granite, quartz, and iron oxides. The quartz sometimes exhibits honeycomb structure; infrequently there is a little clay that may be slightly copper stained.

The fault-veins are similar, except that there is usually one or more well-defined fault clay-walls. "Taking a broad view of the entire copper producing area, it may be said with emphasis that there is but little if any evidence of a positive character to be found in the outcrops or the oxidized zones of the Butte veins to indicate the existence of copper in commercial quantities at greater depths."¹⁰

The manganese-silver veins, forming a crescentic arc to the north of the copper veins, outcrop boldly and may

⁹ *Economic Geology*, 1914, p. 463.

¹⁰ Reno Sales, *Trans. A. I. M. E.*, Vol. 46, p. 1556.

be traced for hundreds or even thousands of feet, on the surface. The zinc veins, closely associated with the manganese-silver series, show as quartz, or rhodochrosite ribs at the surface, the zinc-blende being found 200 to 300 ft. below.

The depth of the zone of oxidation at Butte is exceedingly variable. It depends upon the nature of the veins and the wall-rock, rather than on the topography. The quartz-pyrite veins of the Anaconda system are more deeply oxidized than the fault-veins. The clayey material hinders percolation. Again, the fault-veins are not as heavily pyritized, hence the solutions are not as strong. The oxidized zone shows but little change physically or chemically, from the surface to the sulphide ore, but the change between them is very abrupt. In the Anaconda series enriched ore immediately underlies the oxidized belt, whereas, in the fault-vein system, large areas of barren, unoxidized vein-matter often separate ore-shoots.

In areas of great rock alteration, the rocks and veins are saturated with water. The many periods of fault-

The granite itself is intricately jointed and the climatic conditions are such that boulder-structure is quickly developed, rock disintegration proceeds rapidly, and erosion is advanced. The granite is pyritized along the joints and in the ferro-magnesian mineral constituents. The oxidation of this pyrite would of itself be sufficient to upset the homogeneity of the mass, thus assisting erosion. By oxidizing processes, the feldspars and mica become sericitized. The sulphate waters convert part of the sericite to kaolin and quartz. The present topography is vastly different to that of the mineralizing period, and it is probable that the typical irony outcrops of copper veins have long since been removed by erosion. I have said that other than a rusty staining of the quartz, even limonite is but sparingly developed in the present surface exposure of the veins; this suggests the absence of iron in the ore represented by this remnant. Again, in the oxidized zone, cuprite and some native copper are the most plentiful of the oxidized minerals. These chemical facts, coupled with the physical condition of the district, point to the oxidation of secondarily enriched ores. I consider it highly probable that many of the Butte veins are in the second cycle of oxidizing processes.

Weed says,¹¹ "The quartz-pyrite veins are often distinct, though not conspicuous, but the glance-enargite veins in altered granite can rarely be determined in outcrop; where upraises have been driven to find their apex, it is found to consist merely of kaolinized granite cemented by stringers of quartz. Indeed, one may infer from the absence of limonite that the barren quartz found between the surface and the big orebodies is the result of oxidation of chalcocite and pyrite only.

"The descending waters became charged with ferrous, cupric, and zinc sulphates and have an acidic reaction. All three of these salts are easily soluble in water and all three are carried by the moisture of the air circulating in the mine workings. Such air deposits its moisture by chilling, and as a result many of the old mine workings are coated by efflorescent deposits of zinc, iron, and copper sulphates."

THE METRIC SYSTEM, as applying to American standards of weights and measures, was discussed by Frank Richards in a recent number of the *New York Evening Post*. He argued against its adoption in this country. Regarding the tenet of the advocates of metric weights and measures, who assert that it would be a convenience to American manufacturers in securing trade with the metric countries, such as South America, he stated that the rule works both ways, and that German and French manufacturers are equally handicapped in making goods for our markets or England. Again the metric system was said to be not so scientific as it was claimed to be, because it failed in the facility of continued sub-division by two and three. The advocates of the metric system were stated to be largely college professors, and not the business people who would be affected by a change.

¹¹Professional Paper No. 74, U. S. G. S., p. 39.

ing have, however, brought about local irregularities, and clay fault-dams will cause dry sections, alternating with more open wet zones.

The continued crustal adjustments of the Boulder batholith, particularly that part that was first weakened by vein-forming influences, has contributed to the migration of the metals and so been a vital factor in the economic concentration of the lean primary material.

The mineralogical relations in the Butte veins do not suggest distinct and separate periods of mineralization, but rather one continuous process with varying degrees of intensity.

Reviewing the evidence presented at Butte, the absence of outcrops can be readily explained, and there is nothing in conflict with the ideas I have already expressed concerning the surficial indications of copper. All the ore occurs in one phase or another of a differentiated monzonitic magma. It is confined to definite fractures that have been re-opened subsequently to the primary mineralization or dislocated by later earth-movements. This complex structure has either facilitated or retarded enrichment, dependent on increased facility for deep penetration of meteoric waters by openness of fissures or the damming back of such solutions by the development of fault-clay.

Conditions in Mexico

By Our Own Correspondent

In my letters, appearing on January 29 and June 10, I discussed something of Carranza's extraordinary paper-money system, by which he expected to "save the nation from a public debt and distribute the cost of the revolution equitably among all classes." It is not definitely known, outside the inner governing ring, if the systematic counterfeiting which has been a regular practice of the Carranza Hacienda (treasury) department has inured to the benefit of officials or of the Government itself. A favorite device has been to change the original die, by erasing a line or two, and then to declare false all the previously printed notes from the altered die. Recently the only way to be sure of the genuineness of any Carranza note was to have it officially re-sealed, which not only involved a wearisome delay but the risk of having it destroyed as counterfeit. The unmoral state of Mexican society is well illustrated by the fact that many respectable Carranza partisans defend this official swindling on the plea that "it helps to amortize the public debt."

After the discovery last summer of the wholesale counterfeiting of the ₧50 and ₧100 notes—which culminated in the execution of General Gringás—the Minister of Hacienda, Cabrera, suddenly departed for Europe, probably to escape awkward questioning, but ostensibly to secure a gold loan to back up his new issue of ₧500,000,000 'unfalsifiable' notes, which he had just ordered printed in the United States. Failing in Europe, he started for New York, where he hoped to work on the financiers the same game of diplomatic flattery that Carranza had found so successful among Washington statesmen. But financiers have to pay their own way, and thus, unlike statesmen, cannot afford to cherish any Quixotic illusions as to facts. So Cabrera, in spite of a skillful and arduous social campaign, found himself no nearer his goal of coin than at first, and was finally told that to persist would be useless, as his Government was deemed both incompetent and dishonest. On his return to Mexico in March, Cabrera carefully concealed from the populace the failure of his loan proposals, and soon announced that his plans for the issue of unfalsifiable notes had been perfected and would be put in operation on May 1. During the last week of April, he constructed a new *Comisión de Cambios* of seven members, as he deemed it prudent to have a screen of marionettes to protect himself from the popular odium that the publication of his contemplated financial decrees would be sure to arouse.

During the spring, the press had hinted that the new or unfalsifiable notes would be exchanged for the old notes at par; but the first decree in April announced a ratio of 2:1; while the final decree, by which the issue was

begun on May first, fixed a redemption value of 10 cents (U. S.) per peso for the new notes and $2\frac{1}{2}$ cents for the old notes, or a ratio of 4:1. This promise of redemption of new notes in coin kept their value up for some days, but when it was discovered to be largely a bluff and was being hindered as much as possible at the offices of the *Comisión de Cambios* in order to prevent the escape of real money, their quotation began to drop and was down to 7 cents during the last week of May.

As the decree of May 1 had declared that the old notes should continue as full legal tender until July 1, and thereafter should continue for six months to be receivable for all taxes payable in paper, their holders slept tranquilly on the night of May 31, little dreaming of what would befall them on the morrow. Between June 1 and 3 there was posted all over Mexico a decree that history will doubtless deem the most insane of all the extraordinary efforts of the Carranza régime. The gist of its 14 articles was an abolition of the legal-tender quality of all ₧20, ₧50, and ₧100 notes within three days, after which time such notes would only be receivable as money for a small number of public dues. But if deposited in the Treasury before July 1, they would be paid for on October 1 with gold certificates, which, within five years thereafter, would be redeemed in coin at the rate of 5c. per peso.

But an even worse fate than the nullification of their existing stock of big notes was in store for the merchants, because they were obliged to continue receiving the big notes during the three days following the publication of the decree. A few fortunate ones escaped lightly by closing their stores most of the day and greatly increasing their prices, but many, whose stock happened to be attractive to Carranzista officers, like shoe or hat stores, found themselves beset on all sides and had Hobson's choice of either selling out for worthless notes while at liberty, or of going to jail and having their stock 'intervened.'

But the financial tragedy was not yet over. On June 10 there appeared a new decree declaring that the old notes, which had been declared worth $2\frac{1}{2}$ c. on May 1, were now worth only 1c., and this in future would be valued at only one-tenth as much as the new notes instead of one-fourth. Henceforth, the only remaining legal-tender old notes, those of ₧1, ₧2, ₧5, and ₧10, would have only 40% of their previous value, so that the masses, who had already lost millions by the decree of June 1, found themselves left with practically no money to spend at all.

At first glance it would seem that only a madman could have issued these absurd decrees, which not only repudiated others issued barely a month previously, but

aroused universal indignation even in the Army itself; yet another explanation is plausible: On June 5 the large notes fell to half their former value, so that any paymaster who happened to have a balance of ₧100,000 in small notes could exchange ₧50,000 of it for ₧100,000 of big notes and have a difference of ₧50,000 free and clear for himself, as the accounting rules required his balance to be in legal money, but did not specify its denomination. On June 9 there issued forth, bright and early, from the offices of Nicolas Zembrano, Treasurer of Mexico, scores of clerks carrying satchels full of ₧1 and ₧2 old notes. These eager youths circulated rapidly in the business centre of Mexico City, and offered to everyone ₧5 of these scarce small old notes in exchange for each ₧1 value of new notes, the market rate being only ₧4. Millions were thus quickly sold on June 9 at 5:1;

many employers, "because we have no gold with which to make this purchase." "What do we care," said the Bureau of Labor, "you may do as you please; but remember: if you attempt to close down, a decree is in force providing for the intervention of your plant and stock by the local *prebostal* commission, which will at once put it under the hammer, and from its proceeds pay out a quarter's advance wages to all your patient employees, too long abused by *bourgeois* like you."

Many of the shrewder merchants, discovering some months ago that they surely would fall into bankruptcy if they continued business, and would inevitably be seized by the *prebostal* commission if they tried to suspend operations, have been quietly selling their stock of merchandise. However, this recourse is not open to the owners of mines or factories full of valuable machinery,

AGUASCALIENTES, A SMELTER TOWN IN CENTRAL MEXICO.

these were as readily bought back the next day, after the aforesaid decree had been posted, at half price or at the new ratio of 10:1.

The strikes, in May, of all the workmen of the Carranza railroads and public utilities, for the payment of wages on a gold basis, had been quelled by first declaring martial law, to force the strikers to return to work, and then paying all their wages with new instead of old notes. Naturally, this sudden quadrupling of the pay of public servants made all other workmen dissatisfied, and hordes of them struck for a like change in their wage payments. Many employers offered to compromise by increasing the rate, but continuing to pay in old notes until they ceased to be legal tender on July 1. Yet the strikers would not listen to this and Carranza's Bureau of Labor sustained them in their "righteous objections to such miserly treatment." "Ah," said the beset employers, "we have no new notes, for only the few used for paying the Army and Civil Service since May 1 are now in circulation." "Nonsense," retorted the Bureau of Labor, "the *Comision de Cambios* will sell you all the new notes you may need at the rate of 10c. (U. S.) per peso." "Then we shall have to close our business," answered

and their only recourse is to have such a severe 'accident' to their equipment that operations can be no longer continued.

The author of all this financial legerdemain, Luis Cabrera, was educated for the law, and started his career, like many another attorney of the Diaz régime in Puebla as a go-between for criminals who had money enough to purchase their release from a bench of easily corrupted judges. Later he went to Mexico City, and first entered the limelight about 1908, when he fought a case concerning the water-rights of the Torreón cotton district, against the noted *científico* lawyer, Vera Estañol. Cabrera's remarkable gifts as an orator thereafter kept him well in the public eye till the beginning of the Madero revolution in 1910, when he definitely took the Liberal side by the publication of three open letters against the re-election of Diaz.

When Madero was elected president in November 1912, Cabrera became a member of the Federal House of Deputies, and made a creditable record as an advocate of the restoration to the Indians of their *ejidos* (communal lands) of which they had been robbed by the Diaz ring. After Huerta usurped power in 1913, Cabrera

fled north to join Carranza, and so gained the latter's confidence that he appeared as his spokesman during the military convention at Mexico City in September 1914. About this time F. F. Villareal, the Minister of the Treasury, refused to continue Carranza's policy of unlimited currency inflation, so he was dismissed and Cabrera appointed. Unlike his predecessor, Cabrera had neither a theoretical nor a practical knowledge of finance, but, too conceited to take expert advice and free from moral scruples, he has since persisted in maintaining a national monetary madhouse that has ruined a large part of the middle class, killed thousands of the proletariat by famine and its resultant pestilence, and bids fair, unless foreign relief soon arrives, to exterminate the whole population.

To illustrate what I meant in my June letter by stating that many railroad-cars are the "personal requisite" of some local general, I will take the case of General Medina, long in charge of northern Puebla, in which State are the mine and smelter of the Tezuítlan Copper Co., both shut-down since 1913. The Medina boys, five in number, were born near Matamoros on the Texas border, and, entering the Carranza movement near its inception, had attained high military rank when Carranza came south in July 1914—all except one brother, who remained a civilian in order to manage the business interests of his military family. Controlling absolutely the city of Tezuítlan and its railroad line from Oriental on the Inter-oceanic system, the Medina family now found itself in financial clover, for no freight could move either in or out of the Tezuítlan district without paying them a generous toll.

Other examples of revolutionary patriots are General Luis Gutiérrez, brother of the unfortunate president, Eulalio, last heard from as a fugitive in the mountains of San Luis Potosí, who up to 1911 worked by the day as an *icil* (maguey fibre) laborer. This year General Luis was sufficiently flush to advance \$1,000,000 to a business partner, General Francisco Coss, who, before the Revolution was a small farmer in Coahuila, but is now established at Saltillo as the *icil* 'king,' using a capital obtained chiefly from his profits for a year as Governor of Puebla. General Candido Aguilar, now Minister of Foreign Relations, was governor of Vera Cruz for some 18 months, and, though just able to write his own name, has found his ignorance neither an obstacle to political preferment nor a hindrance to the rapid accumulation of a fortune of several million dollars, which is now safely banked in the United States.

Of all the Carranza leaders, Dr. Atl is probably the most intellectual; and for long after he first became prominent, in January 1915, his antecedents were a mystery to the public, for he goes under an assumed name. Since then his history has gradually been revealed. Born in Guadalajara, at an early age he developed talent and was sent to Paris to be educated as an artist. While in France, he became interested in syndicalism, and soon became an enthusiastic anarchist. On the fall of the Madero government he joined the staff of

the Paris organ of the Mexican liberal party, and when Huerta fled in 1914, Atl had just landed in Vera Cruz on his way to Mexico City, for the purpose, it is said, of assassinating the tyrant. Balked by Huerta's flight, Atl decided to join Zapata, but on his way to Cuernavaca, he was captured by one of Zapata's generals and condemned to be shot as a spy. Just before the sentence was to be executed, Atl gained a parley with his jailer and such were his powers of persuasion that he not only obtained a pardon, but a safe conduct to Zapata himself. Soon he had become the confidential adviser of the wary brigand, and thus continued for several months until, convinced by his natural shrewdness that Carranza would be the final winner, he escaped to the lines of the First Chief. After various adventures, he finally obtained a job with General Obregon as organizer of his Mexican 1st W. W. Atl has an all-around artistic temperament, and it is as orator and writer, rather than painter, that he has proved himself invaluable to the Carranza ring; for, in the exercise of his unusual talents, he is not hampered by any of those spiritual visions or moral ideals that have rendered so many of the world's geniuses of no earthly use to 'practical' men. The depravity of the triumphal revolutionists is partly explained by the fact that during the advance of the rebels against Huerta in 1913, it was their policy to open the jails of captured towns on condition that the prisoners enlisted as soldiers. And though this policy is not now recognized by the Carranzistas, it is still the custom of the Zapatistas. It is a curious fact that the followers of Villa, the bandit, generally paid for the forage and food they took from the ranchers, while the soldiers of Carranza, the statesman, seldom pay for their forage even now. In fact, the live-stock and poultry of the farms in southern Mexico were long ago declared to be by nature 'Zapatistas,' and therefore liable to capture on sight. In 1914 and 1915 many green crops were either cut for forage or trampled by pasturing horses, and were thus a dead loss to their cultivators. So this year, in spite of the high prices and the decree of 1915 (allowing anyone to cultivate land if the owners do not) only a fraction of the normal average has been planted. This is the case especially in the vicinity of towns garrisoned by cavalry.

The use of Vera Cruz by Carranza as his capital from November 1914 till his re-capture of Mexico City in August 1915 is explained by its manifest advantages as the seat of custom duties and as the port for an easy escape in case his army was defeated by the Convention. But his fixing of his next capital at Queretaro, instead of accompanying his Federal departments to Mexico City, in September, is more of a mystery. It is probable that fear of a re-capture of the City by the Zapatistas and of assassination by some of his political enemies or the relatives of his victims combined to make him shun the Nation's capital as long as possible.

Yet the merchants of Mexico City were told to prepare for Carranza's coming by erecting a line of triumphal arches stretching for the league between the National Palace and the castle of Chapultepec. Where voluntary

subscriptions were not forthcoming to cover the cost of the arches, fines were imposed. Expected in December, Carranza did not arrive until April, and even then he came into town secretly, foregoing a triumphant entry. The following week, the populace was regaled at night with electric illuminations and one afternoon by a welcoming procession of police, soldiers, and peons, collected in the suburbs, which Carranza reviewed from a balcony in the Zocalo. Next day the Government press announced that Carranza was offended by the failure of the professional and commercial classes of the city to greet him with enthusiasm, and that a merited castigation was in store for them. Is it possible that the dreadful financial decrees of June were issued in fulfillment of this threat? Sure enough, on June 5, ₧600,000,000 of genuine notes became practically worthless and thousands of artisans and middle-class civilians, as well as soldiers and servants, walked the streets of the capital with hands

food-growing capacity. Thus there were few city people to be fed from outside, and in the absence of foreign-owned railroads to "intervene," the military satraps could not obtain a monopoly of produce transportation.

Moreover, the exportation of low-priced and bulky foods was a slow affair when they had to be carried from the central plateau to the distant coast on mule-back; and, in the absence of a depreciating currency, there was little profit in exporting even the common produce of the coastal plains. With only coin in circulation, the purchasing power of money was never affected by revolutionary activity, and should the sustenance of one district be depleted, it could easily be obtained in a neighboring district or country with the metallic savings of the inhabitants.

The export of last autumn's crop has left the whole country practically bereft of food, and from the scanty acreage now planted there seems little hope of any les-

A REGIMENT OF MEXICAN SOLDIERS.

full of big notes that would no longer buy them even the cheapest food. The indignation against the Government among all classes was intense and the common feeling was voiced by this overheard remark: "Up to now I had some doubt if our terrible political condition arose from ignorance or dishonesty; but this last decree has convinced me that the Carranzistas are simply hypocritical bandits." Yet there apparently were to be no reprisals or revolts against these bandits by the outraged people, for the simple reason that no Mexican dares to trust another. Thus conspiracies like the Ku-Klux clan of the South or the Vigilance Committee of the West are unworkable in Mexico, and we now find a population of 15,000,000 disarmed and terrorized *pacíficos* being starved and abused with impunity by less than 200,000 Carranzista and Zapatista soldiers, who for years have been having a continual picnic at the expense of foreign investors and the native owners of property. It may be affirmed that no former revolution has ever caused in Mexico such widespread suffering as the present one, for in the old days, preceding 1876, there were no railroads or paper money. Then, the population was mostly rural and was distributed over the land in proportion to its

sening of the famine after this year's harvest, even should the nefarious export operation of the *Casa La Garda* be cut off entirely. In the country the great estates that are still in operation will manage to provide food for their peons, and the small farmers and the Indians of *ejidos* can raise enough for their own use. But the proletariat of the numerous cities is even now in desperate straits and, unless some arrangement can be made for their wholesale feeding by imported food during the coming year, they must soon begin to die like flies, of starvation.

Why Carranza is now trying to provoke the United States to war is not exactly clear. In the light of his own record in particular, and of Mexican character in general, his base ingratitude to President Wilson, who may be said to be the creator of this political Frankenstein, is not at all surprising, but what has Carranza to gain by a fight? Unsupported by the masses, he apparently relies chiefly for safety on a union with Zapata and Villa. Can it be that the fates have relented, and that Mexico, like the Sudan, may now hope for a brighter future after the slaughter of all her banditti has once been achieved at some western Omdurman?

Discrepancies in Cyanidation

By Edmund Shaw

AS SOON as crushing in cyanide solution became a common practice it was found difficult to check the theoretical extraction of the mill with the bullion actually recovered. Sometimes there was a super-recovery, but more often a shortage, for it is a weakness of human nature to estimate on the 'long' side, and one has always to contend with the innate depravity of things. A part of the difficulty must be laid to the new spirit in mining which demanded careful estimates based on observed and recorded fact in the place of guesses. A lot of new problems came up and ways had to be devised to find the answer; for example, the method of figuring tonnage from the specific gravity of the pulp. The mill-man found he had to become a metallurgical book-keeper, or hire one; and sometimes discrepancies persisted and experts had to be called in to find out why.

In order to keep the mill-books straight, a practice has arisen of using what is called the 'bullion plus tailing' method. The sampling of the ore entering the mill is disregarded, the value per ton of the mill-headings being arrived at by adding the value of the bullion recovered to the value discharged in the residues, dividing by the estimated number of tons. Really this is no check whatever upon the work. The only comment necessary is that one large mining company has admitted in a published statement that by using this method there was an unsuspected loss of \$65,000 per year, that was not discovered until better methods of assaying, sampling, and record-keeping were introduced.

The books of a mill should not differ essentially from the books of a manufacturing or mercantile business. The mill should be charged with the value of the ore received from the mine, as determined by the daily sampling, assay, and tonnage determinations, and credited with whatever it produces in bullion and residue. Whenever a statement is made, account must be taken of the ore in the bin and in process of treatment, and of the value in solution and in the precipitation department, etc., and this account must be occasionally checked by stock-taking exactly as a factory checks up its finished and unfinished product on hand. As sampling and assaying are not exact, there will be shown a slight difference on one side or the other, which goes into an account called Unaccountable Loss, corresponding to the Suspense Account of an ordinary set of books. The effort of the mill-man should be to keep this unaccountable loss at a minimum.

The causes of any difference between theoretical and actual extraction will all be found under one of the following:

- (1) Theft.
- (2) Leakage and waste.

- (3) Errors in estimation of tonnage.
- (4) Errors in sampling.
- (5) Errors in assaying.

(1) Theft is suspected more often than it occurs. In a great many years' experience in milling, I have never seen a shortage that could be credited to theft, and in the cases of which I have knowledge the evidence of broken locks and tapped zinc-boxes was so plain that it could not be mistaken. The only places that need protection are the precipitation department and refinery, and it is a simple matter to confine the responsibility for these places to a very few persons.

(2) Leakage in old and badly-built mills may be a serious matter. But few instances are recalled in which this was not the case. The worst was in an old mill, which had leaky mortars. The solution drained away in a dark place behind the mortars and ran into a creek that flowed by the side of the mill. The loss was thought to be insignificant until an assay of the creek-water showed it to carry considerable value. Leaky launders, and launders that overflow from having insufficient grade, account for some loss and a badly-built elevator that stops or breaks down will often cause considerable waste. But, taken as a whole, these are small matters and ones that even the most careless of mill-men will see and remedy. Perhaps the commonest waste about a cyanide mill is that which occurs in cleaning up and refining precipitate. This always amounts to something even where the work is carefully done, and it has been published that losses as high as 6% of the output have been traced to this source.

(3) Errors in estimating tonnage are a frequent source of discrepancy. In large mills such errors can be reduced by the use of automatic machines for weighing and sampling, but the capital cost is too great for the small plant. Weighing and sampling cars by hand is considered too expensive, so the usual method of estimating the tonnage of ore delivered by the mine to the mill is to multiply the number of cars by a 'car factor.' This car factor is obtained by weighing all the cars delivered to the mill-bin over a period of time and sampling them for their moisture content. From the weights and moisture determinations, an average figure is obtained that is henceforth used to determine the daily tonnage by multiplying it by the number of cars for the day. Where the ore is clean and fairly dry, and the mine-cars are all of the same capacity, this method gives reliable figures; but if the ore is wet and sticky, so that the moisture-content of individual cars varies greatly, and the cars do not empty cleanly, it will give unreliable results, especially if the estimation is further complicated by the use of cars of varying capacity. In the case of one such

wet ore, the moisture-contents of cars have been found to vary from 6 to 17%. The amounts left in the cars after dumping varied from almost nothing to nearly 100 pounds. It has happened at the plant referred to, that the car-tonnage has varied more than 10% from the tonnage that had passed the mill during the month, as determined by fairly exact methods.

Another method of determining tonnage, but little used in cyanide mills (except in getting at the work of a particular machine, such as a battery or tube-mill) is the five or ten seconds sample. All the pulp from a battery—for example—is run into a tub or other receptacle, for five or ten seconds, the time being taken by a stop-watch. The average of a number of tests is taken to figure the tonnage per stamp-hour or other unit. Here again the character of the ore has everything to do with the accuracy of the method. It is accurate if the ore is all the time of about the same character, but if the mill is running part of the time on hard quartz and the rest of the time on soft clayey ore that washes through the screen with practically no crushing, it cannot be relied upon.

The best method, and the one now in common use in plants, is that based on specific gravity. In this method the stream of pulp somewhere in its course is run into a tank of known dimensions, and measured and sampled for a determination of its specific gravity. Calculation or reference to a table gives the tons of dry solid in the volume measured. But even then there are opportunities for error. In many cases, the tank is not evenly agitated when the sample is taken. In the ordinary mechanical agitator used as a stock-tank for filters there will usually be found a difference in the specific gravity of the pulp at the centre and at the outside of the tank. It is easy to make a mistake in filling the weighing-flask from the sample if the pulp is at all thin and contains sand. The tank in which the measuring is done will usually be found 'out of round' and allowance is necessary for this in making up the tables. Measurements should be made from water-level to water-level instead of to the bottom of an empty tank, which usually has an irregular bottom of sand. And, finally, care must be taken that slime does not 'build up' on the side of the tank so as to decrease its diameter. An inch coating on a 30-ft. tank represents no inconsiderable amount of dry slime. In a word, those who are in charge of this work must be taught to appreciate its importance and to do it carefully. Most errors in tonnage determinations are cumulative; while small for a day, they may grow into large amounts in the course of a year or even a month.

It is almost too elementary to point out, but it is a fact sometimes lost sight of, that there is often a difference between the car-tonnage and the tonnage passing the battery, and between the battery-tonnage and that which has passed the mill and been discharged as residue. Improper accounting of tonnage which disregards this fact has sometimes shown a serious shortage where none existed. Take the case of a mill that has been running with a short ore-supply for a considerable time. The

mill-bin is empty, storage-tanks and thickeners are 'pulled down,' and everything in solution is precipitated so far as possible. Now, if the supply of ore is suddenly increased beyond the capacity of the mill to handle, the mill-bin will be filled, the stock-tanks and thickeners brought back to the normal running-point, and the amount held in solution will be increased. If at this point a clean-up is made, a large shortage will be shown if the recovery is figured on the car-tonnage, less shortage if figured on the battery-tonnage, and least if figured on the residue-tonnage; and only a complete stock-taking will show the true state of affairs. Probably, every mill superintendent of much experience has had to explain this at some time to a manager or a director. I know of a case in which a small mill was shut-down and everything about the plant cleaned-up in order to satisfy a director that 'something was not wrong,' mere figures having entirely failed to convince him.

A highly important tonnage determination is that of the solution passing the precipitation-department each day. But this presents no difficulty, as it can be accurately determined by one of several methods. The best is the meter, which can be bought or made at the plant, the tilting-box being the usual form. A good way is to run the solution into alternate sumps of known capacity and keep a record of the levels of solution before and after pumping, and, if no other way can be used, a fairly good estimate can be made by measuring with the ever-useful five-gallon can, every two or four hours. In passing, it may be noted that there is no more useful record than that of the quantity and assay-value of the solution going to be precipitated. Properly understood, it is a check on several things and a source of valuable information about the running of the plant. No plant should be run without this record.

(4) The difficulties met in sampling are too thoroughly discussed in the standard text-books to need much emphasis here. The head or feeder sample is the mill-sample that gives the most trouble. If Richards' law is followed, the resulting sample, from ore broken to the size of stamp-mill feed, is so large that the work of crushing and cutting-down appalls the assayer or whoever has it to do. As a matter of fact, it is not necessary to follow this law. A smaller sample may give too high or too low a figure for a single day, but it will be balanced by too low or too high samples in the days following. This is said of mills that run steadily, and on ore that does not vary too much in value, as mills should run. At the same time it is not wise to leave too much to the law of averages; as big a sample as can be conveniently handled should be taken.

Sometimes a sample is taken from each car before it is dumped into the crusher, but this practice is to be condemned. It is impossible to sample ore accurately by grabbing a handful out of a car and if the fine carries a higher value than the coarse ore—as is usually the case, the result will be too high.

Ordinarily, the sampling of the residue presents no difficulties, but I recall two instances in which bad resi-

due sampling led to very serious discrepancies. The first was in a leaching-plant. The tanks were filled by a Butters distributor and no care was taken to keep a head in the hopper. Consequently, the pulp classified, the coarse sand going to one side of the tank and the slime and fine sand going to the other. In leaching nothing was extracted from the slimy side of the tank, but a good extraction was obtained from the coarse sand. The residue was sampled by a split pipe made from an old vanner-roller. It gave a good core from the sand, but almost nothing from the slime. A residue was discharged, supposedly containing only forty or sixty cents, which really contained some three or four dollars. It would be hard to find such an exhibition of ignorance and carelessness in a cyanide-mill today.

The other case was in a filter-plant. The residue-sample was taken by scraping off a little of the cake from a point about a foot below the head of the leaf. In investigating the causes of a discrepancy, a leaf was pulled up and the adhering cake measured and sampled at the top, middle, and bottom. The bottom of the cake was found to be twice as thick as the top, and it assayed three times the value of the top. The information thus obtained went far toward explaining the discrepancy. The reason for this irregular cake-forming was that the crushing was very coarse for an 'all sliming' plant, and the sand in the pulp settled slowly during the cake-forming period.

(5) Mistakes in assays are far commoner than is generally thought, and discrepancies have often been traced to them. A persistent super-recovery has been noted in some silver-mills and explained by the fact that the proportion of loss in cupelling silver is much greater on a large button than on a small one, especially if the work is carelessly done; hence, the head sample is reported too low.

But, far greater discrepancies arise from trying to assay a pulp containing dissolved gold by 'drying down.' Assays made in this way are quite unreliable, a fact that was not generally known until a comparatively recent date. A good many puzzling discrepancies were then explained. If the dissolved value is very low, the loss will be negligible, but if it amounts to as much as 40 cents, a 50% loss may take place during the assaying.

It is the residue-sample that is principally affected by this loss, and there is only one way to avoid it; that is, to wash out the dissolved gold by filtration or decantation, or both, and to assay the washed pulp and the washings separately, and to combine the assays in proportion to the weights they represent. This looks difficult, but the work is not excessive if proper arrangements are made. Where connections can be made with a vacuum-line, the best way is to have a small filter made of tin. This filter has a receptacle for catching the wash drawn through. The residue-sample is mixed with water and a sample taken for specific gravity. To make sure of this, since it is most important to be certain of the proportion of solution and solid, a wide-mouthed bottle, such as a pickle-bottle, may be used for both mixing and weighing.

The mixed pulp is poured on the filter and pulled dry, and the solution taken from the receptacle for assaying. Then the pulp on the filter is thoroughly washed with water, and if the bottle is used, it may be rinsed out with the wash-water. Since the pulp then contains no appreciable value in dissolved gold, it may be dried and assayed like any other ore-sample. To save time, it is usual to prepare a table showing the ratio of solution to solid for different specific gravities, and to use this in making the calculation.

This method is now in use in many plants and has proved itself reliable. An alternative method is to precipitate the dissolved gold with cuprous chloride or other reagent and then to evaporate to dryness. But, in my experience, this has not proved satisfactory. Any assayer can see reasons why it is difficult to cut down a sample containing precipitated gold, not to speak of the slight error that results from adding to the weight of the sample.

Errors in the precipitation-record often come from improper assaying of the solution going to the precipitation-plant. The method of assaying by the use of zinc-dust and lead acetate is simple and in almost universal use, but some care has to be taken or it will give low results.

It may finally be noted that discrepancies are usually found in old and badly-designed mills, and in mills that do not run regularly, either from break-downs or an irregular ore-supply. Steady running on ore of fairly even grade goes far to ensure good checking, as it goes far to ensure good milling in other ways.

THE RUSSIAN EMPIRE is the largest of all countries, having an area of 8,417,115 square miles, which is more than double the area of the United States with Alaska and all island possessions. In population Russia is surpassed only by China and India. In 1913, Russia's population was 174,000,000. Siberia alone has an area twice that of the United States proper and a population of only 10,000,000, equivalent to that of New York State or Canada. It is not generally realized that Russia's cereal and potato crops greatly exceed those of the United States; Russia also has more horses, sheep, and goats than this country, although not so many cattle and hogs, the total of all live-stock being about the same. The Russian Empire has a larger forest area than any other country. Many commercial and business enterprises in Russia have been financed by French capital.

Mining was discussed by A. A. Cole in his presidential address before the Canadian Mining Institute. He said: "Talk to the man on the street and you will be amazed in nine cases out of ten to find that he does not realize the basic difference between a mining and an industrial enterprise. He will tell you that a mining proposition should return twice the income of an industrial concern because it is more risky. He has, in fact, never thought of the extra profit as a sinking fund or return of capital."

The California Gasoline Industry

By W. R. Hamilton

†The knowledge of the existence of petroleum in southern California dates back to the days of the missions. The presence of asphaltum and semi-solid bitumen was reported at Santa Barbara in 1792, but no serious attempt was made to develop oil until Professor Silliman's optimistic report in 1865 started California's first oil boom. Wells were drilled in many counties of the State, but the equipment was unsuitable and the drilling difficult and no production was obtained except in Ventura county. Even there production was of little importance commercially, and not until the early '80s did it become sufficient to again attract attention. In 1888 the production for the State had reached a total of about 700,000 bbl. per year, practically all light oil produced in Ventura county, Pico canyon, Los Angeles county, and in the Puente hills. The production of petroleum attained the dignity of an industry in 1895 when the Los Angeles City and Coalinga fields were discovered. The subsequent development has been remarkable, and in 20 years the production has increased from 1,000,000 to 100,000,000 bbl. per year.

The refining industry has kept pace with the production of oil. The Pacific Coast Oil Co., the predecessor of the Standard Oil Co. of California, was the virtual pioneer refining company of the State, having built a refinery at Alameda about 1880. When purchased by the Standard Oil Co. about 1902, it was dismantled and the refinery at Point Richmond was built. The Richmond refinery is now one of the largest in the world, having a capacity in excess of 60,000 bbl. per day. A small refinery was built by the Union Oil Co. at Santa Paula in the early days of the industry and later many asphalt refineries were in operation in southern California. The Pacific Coast Oil Co. was then, as has been its successor, the Standard Oil Co. of California, the principal refiner and marketer of light products, the most valuable of which was kerosene.

Before the opening of the twentieth century, gasoline of excellent quality was produced, though it was always a drug on the market and was produced for the simple reason that its presence rendered the flash and fire tests of the kerosene too low. The user of kerosene at the present time obtains a safer and better oil than he might receive had not the value of gasoline been increased by the increased demand.

The phenomenal development of the California oil fields in the earlier years of the twentieth century was principally in oils of such heavy gravity that they were

used in the crude state for fuel. During the last six years, which has included the 'gusher' period of the Midway fields, the production of refinable oils has increased greatly, while, strange as it may seem, the production of heavy non-refinable oils has decreased. During this period, from the beginning of the present century, the introduction and perfection of the automobile has changed gasoline from a despised and troublesome by-product to the most valuable and important product of the crude oil. The production of light oils did not keep pace with the demand for gasoline and as a consequence the price of gasoline increased from about 16c. in 1904 to 25c. in 1910. The shortage was reflected in the prices paid for light crude. In the feverish development period which resulted, an enormous increase was shown in its production, until in 1914 the output of light oils capable of being refined was in the neighborhood of 50,000,000 bbl. The resulting gasoline being considerably in excess of the demand, prices began to fall in 1911 and, aided by importations of gasoline from the Dutch East Indies, the price rapidly declined to a low level of 11c. per gallon in the summer of 1915.

The late increase in the price of gasoline is ascribed to the following causes:

1. Decreased production of refinable oil. The decrease probably amounted to about 6,000,000 bbl. in 1915.
2. Steadily increasing consumption.
3. Discontinuance of gasoline imports due to increased European demand.
4. Heavy exports due to European war.

All of these conditions may reasonably be expected to exist for some months to come. There is no reason to expect a reduction in the rate of consumption. The acceleration of the growth of the automobile industry shows no decrease and, with the rapidly increasing mileage of improved highways in California, an increase rather than a decrease may be looked for. It is unlikely that gasoline will be imported from the Dutch East Indies so long as it is possible to deliver it to the European market. The serious shortage of oil in the Eastern and Mid-Continent fields, which developed in 1915, and which resulted in cargoes of gasoline being shipped from California to Europe, does not as yet show evidence of alleviation, and the only prospect of production reaching consumption seems to rest in the discovery of another phenomenal field such as Cushing, Oklahoma. Unless the Eastern fields can increase their production it is to be expected that further exports will be made from California.

There is no doubt that, unless the year 1916 shows a considerable increase in the production of gasoline, which is unlikely, or unless a satisfactory substitute for use in

*Consulting geologist, Insurance Exchange Bldg., San Francisco.

†Paper to be presented at the Arizona meeting of the American Institute of Mining Engineers, September 1916.

motor vehicles is provided, we face a serious gasoline shortage on the Pacific Coast.

Increased production of gasoline may come from one of the following causes:

1. Increased production of light oil.
2. Increased production of casing-head gasoline.
3. Lowering the grade of market gasoline.
4. Innovations in refining methods, such as the Rittman, Burton, Snelling, Cosden, McAfee, Wells, Kelsey and Washburn processes.

1. There does not appear to be more than temporary relief to be looked for in increased oil production. All the principal fields have apparently nearly reached the height of their productiveness and while some may increase, the decline of the others will probably outweigh their gain. Unless I am greatly mistaken, the year 1914 will long remain the banner year of California's oil production.

2. The production of casing-head gasoline, which is based on the recovery of the lighter hydrocarbons usually lost in oil production by volatilization, is of recent development. At present it accounts for less than 10% of the gasoline marketed in the State. Owing to the low price in 1913 and 1914, the increase of gasoline produced in the gas industry has been retarded. Several new plants, however, are now under construction. The gas amenable to such treatment is limited, and it is unlikely that the new production of gasoline from this source can be expected to have any marked effect.

3. By lowering the grade is meant including higher boiling-point fractions in the gasoline as the cut is made at the refinery. Before the demand for gasoline was great, the gravity of marketed gasoline was about 65° and even as light as 72° Baumé. The boiling-point of the 'last over' or the end-point of the distillation of such a gasoline was little higher than 200° F. With diminished supply and increased demand, the gravity has been gradually decreased until the present standard is from 59° to 61° Baumé with an end-point from 320° to 380° F. The cut in the refinery distillation is, therefore, widened and the production of marketable gasoline produced is thereby increased. If no other way is found to supply the demand, this cut can be widened still further while continuing to furnish the motorist a satisfactory fuel. The production can probably be increased from 30 to 50% in this way.

4. The processes mentioned show considerable promise. They depend for their success upon being able to break up the molecule of high boiling-point hydrocarbons into lower boiling-point molecules. The processes may be divided into two main classes, those which depend upon excessive heat or pressure or both and those which depend upon a catalytic agent.

The most notable of the former are the Burton and Rittman processes. The Burton process, which was patented by William M. Burton in 1912, is controlled by the Standard Oil Co. After many difficulties have been overcome and much money expended in experimental work, this process has been made successful and is now

being installed in many Standard Oil refineries. Much difficulty was first encountered in producing an article that was of good color and odor. This has been overcome and the Burton process now gives the Standard Oil Co. an important advantage over its rivals. So far, it has not been successfully applied to California asphaltic oils where the presence of a large proportion of unsaturated hydrocarbons results in difficulties not experienced with the oils from the Eastern fields.

The Rittman process is the result of the research work of W. F. Rittman of the U. S. Bureau of Mines. The process has already been successfully applied to the commercial manufacture of toluene and benzene. It differs from the Burton, Snelling, Cosden, Washburn and Wells processes, in that the action takes place after the liquid has been vaporized. By subjecting the vapor to pressure and heat, a re-arrangement of the molecules is effected, liberating carbon which is removed from the plant without difficulty. The process shows much promise and, while much remains to be done before it can be considered a commercial success, it has created a profound impression among refiners. Under the rulings of the Government, a Federal employee may not profit in this country from any discoveries or inventions during his connection with the Government. The foreign rights will be controlled by Dr. Rittman. The Government proposes to allow anyone to use the process under license, and it is probable that the increased value of gasoline and the handicap confronting the 'independent' refiners on account of the Standard's control of the Burton process will result in an early attempt to perfect the process. It has been perfected as far as is possible in the laboratory stage and its future depends upon the results of its application on a practical scale.

Of the processes making use of a catalytic agent, the McAfee process, which is controlled by the Gulf Refining Co., is the most promising. The catalytic agent is aluminum sulphate, and results from experimental work are said to be excellent. However, this process, like the Burton, will probably be unavailable to other companies.

The future has generally cared for itself and will undoubtedly do so in the gasoline industry. While we shall probably have a gasoline shortage extending well into 1916 and perhaps into the early part of 1917, the result will be redoubled interest in the subject of perfecting such ideas as have been brought to light in the experimental work done in the above-mentioned processes. The research work of Dr. Rittman and other able scientists who are working on the problem, bids fair to develop a practice which will revolutionize the refining industry.

GOVERNMENT reports, it is suggested by R. E. Hore, would be more read if they were more concise. Verbose publications are likely to be thrown away or shelved. A considerable saving could be made by intelligent editing or even by changing the usual wasteful typographical arrangement.

Silver

Silver prices are fairly high, but those who watch the market may note by the fluctuations that it is sensitive. According to Messrs. Pixley & Abell of London, China and India are still the cause of weakness, and sales from one or other of these quarters have been in evidence almost daily, with the result that large buying orders for coinage have been easily filled. So much depends on the attitude of China toward this market that the immediate future is most difficult to forecast. Looking farther ahead the prospects statistically seem favorable for the following reasons:

(1) The low level that the stock of rupees in the currency reserve of India has reached, in spite of purchases amounting to some millions sterling, a good deal of which has already passed into currency, points to a continuous drain on this reserve, and it seems probable that the Indian government will have to continue coining for some time to come. (2) The British mint's requirements will probably continue. This year £2,200,000 has been absorbed for coinage in England. (3) The demand for silver by the Allies is likely to be maintained so long as the War lasts. In spite of important purchases, the stock of silver in the Bank of France has been reduced by £1,000,000 during the past year. (4) The probability of the retention in the country of a large portion of the Mexican production for the purpose of re-establishing the currency. (5) It is questionable whether China, having already sold such large amounts of silver, is in a position to part with much more. According to latest advices the stock of 'sycee' (60-oz. bars) in Shanghai is reduced to 26,000,000 taels (35,500,000 ounces). (6) The world's production of silver is decreasing. In 1915 the total production was estimated at 196,000,000 fine ounces, against 211,000,000 in 1914. For these reasons the future of the market, from a purely statistical point of view, seems favorable.

Regarding Egypt as a factor in silver, the Egyptian correspondent of the *Pioneer Mail*, on March 10, wrote as follows: "Every year we have a silver 'crisis,' usually in the early autumn, when large numbers of laborers have to be paid daily throughout the country in connection with the cotton crop; but the crisis usually is over by Christmas, being met by imports of newly minted coin that has to be obtained in the ordinary course. The War has, however, completely changed the situation. The increase in the army has necessitated the putting into circulation of far more nickel and silver currency than ever before, and the financial authorities took early steps to obtain the necessary extra supply. Things would not have been so bad if the shipments in the *Persia* and the *Malaja* had not been lost. During 1915 new coin to the value of £720,000 was imported, whereas the average of the preceding five years had only been £140,000, and the previous recorded maximum annual import was £694,000 in 1896, when the system was remodelled. The Sudan, it should be mentioned, uses the same currency as Egypt and a good deal of British gold

and Egyptian silver remains every year in the interior of that dependency. India appears to have been the only part of the Empire that had any silver coin to spare, and by special arrangement the Egyptian government imported a certain quantity of silver rupees, which, it is stated, have now been declared legal currency in the country. Whether in order to facilitate trade between Egypt and the Sudan, they will also be made legal currency in the latter dependency, is not known."—Abstract from weekly letter of Samuel Montagu & Co., London.

THE SILVER production of the world has averaged about 200,000,000 oz. per annum, worth approximately \$100,000,000, since 1900. This compares with an average annual output of gold during the same period of more than \$400,000,000, or four times the annual value of the silver. The world's output of silver in 1915 is estimated at 196,000,000 oz., of which the United States produced about one-third, Mexico, Central and South America another third, and Canada one-seventh, the remainder being contributed by Australia, Japan, and other countries. The figures for the world's yearly production of silver since 1860, issued by the Director of the U. S. Mint, show that the increase has been gradual, from 29,095,428 oz. worth \$39,337,000 in 1860 to 211,339,749 oz. worth \$116,849,900 in 1914. But from 1893 to 1906 the output remained practically at a standstill; in fact, the production in 1893 was worth slightly more than that of 1906, the value being \$129,119,900 in 1893 against \$111,721,100 in 1906 for approximately 165,000,000 oz. in both years. This was due to the decline in the silver market. In 1912, when the production of silver reached 224,310,654 oz. worth \$137,883,800, the value was but little greater than in 1891, when the output of 137,170,000 oz. was worth \$135,500,200. The recent rise in the price of silver was explained in a nutshell by Samuel Montagu & Co. of London, as follows: "The quotation fell quite as heavily when silver was demonetized upon a large scale; now an exactly reverse operation is taking place. Silver is being monetized upon a large scale."

JAMES J. HILL's comment on financial and national questions was always interesting and usually sound. In a letter written just before his death, and printed in the *Analyst*, he said, regarding the nation's banking system: "There should be one and only one Federal Reserve bank for the United States. This should be located at Chicago, the central city of the country, where it would be safe from danger of naval attack in case of war. It should be the centre and directing influence in financing the business of the country, dealing of course only through other banks. There is much less danger of abuses from a single central bank than from a dozen local banks. The division of the country into districts, drawn haphazard, was and is a mistake from every point of view."

EXPORTS from the United States to the extent of 10% in value, or 35% in bulk, are carried in American ships.

CONCENTRATES

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

GERMAN SILVER contains 60% copper, 21% nickel, and 19% zinc.

LOCOMOTIVES on 40 railroads in the United States use oil for fuel. In 1915 there was 36,648,466 bbl. consumed in this way.

Loss of copper in tailing and slime at Anaconda before flotation was introduced was about 16 lb. of copper per ton. Since the introduction of the flotation process, the loss does not exceed 1½ lb. per ton.

SERBIA has one good copper mine, the Bor, operated before the War by a French company that paid 60% in dividends for several years. The ore resembles that of Butte and averages 6% copper. The output was 7500 tons of metal per annum.

AN AEROPLANE is used to make daily trips from tide-water to the Dolly Varden mine, 14 miles inland in British Columbia, says a newspaper report. This is for sending supplies to the mine, and the service is said to be rendered by the California Aeroplane Co. for \$600 per month.

FOR TEMPERING drill-steel it is good practice to have a wire netting several inches above the bottom of the tempering-tank. This prevents the bit, when being cooled in the bath, from standing in the accumulation of sludge in the bottom of the tank. Breakage of drill-steel used in hammer-drills is increased by continuing to use bits after they have become dull.

THE VISCOSITY of different furnace slags is being investigated by the U. S. Bureau of Mines at Pittsburg. An apparatus has been devised to measure the viscosity of slags by a torsion method, the torque being indicated by a mirror and scale. Several surprising facts, contradictory to the ordinary properties observed by the eye, have been disclosed by the measurements.

PYRITIC SMELTING and its advantage was first suggested by John Hollway, who pointed out that copper ore from Rio Tinto, Spain, containing much iron pyrite, could be smelted by the heat mainly derived from the oxidation of the iron and sulphur. Later, in Tasmania, Robert C. Stiehl applied pyritic smelting to Mount Lyell ore. The Tennessee Copper Co. further perfected the practice, under the direction of W. A. Heywood. Only a small addition of coke to the ore is required, about 2%.

'HIGH-SPEED' TOOL-STEEL, so-called, containing tungsten, chromium, etc., is not as hard as ordinary high-

carbon steel, and usually can be scratched with a good file. Its resistance to cold wear is less than that of heat-treated high-carbon steel. The special property of 'high-speed' steel, such as tungsten-steel, lies in the fact that it may be used at a speed six times faster than ordinary carbon-steels, without being softened by the frictional heat.

DETERIORATION of an explosive comes from storage in a climate where rapid changes of temperature are usual, as hot days and cool nights. The explosive assumes a dark color and loses its elastic consistence. Nitroglycerine separates from the compound and shows as an oily layer on the paper wrapper. When an explosive has been stored in a moist place, a fine salty powder of saltpetre becomes crystallized on the wrappers. Such explosive should not be used, as the uniform intermingling of the constituents has been changed.

USE OF POWDERED COAL for generating steam is still in the experimental stage. Steam can be efficiently produced by this method, as regards combustion and evaporation. The loss in the ash-pit and the flue is less than 1%. The cost of fuel preparation, however, is high, and conditions have to be favorable for the practical use of powdered coal. The great success of powdered coal lies in its adaptability for metallurgical furnaces, as in the coal-dust firing of large reverberatories at Anaconda and Garfield, and for the firing of locomotive-boilers.

AERIAL TRAMWAYS are well liked for transporting ore over rough country. The cost of moving ore by this method where the distance is 2 to 5 miles is usually not more than 3 or 4c. per ton-mile, say 8c. for moving the material 2 miles and 12c. for moving it 5 miles. For shorter distances the cost does not decrease much, as the expense is principally at the terminals. However, in a well-regulated tramway less than a mile long, operating with self-dumping buckets, the cost may be as low as 4c. per ton. Where only a small quantity is handled, say 100 tons per day, the cost becomes relatively high, because over-head expense is proportionately large.

BOILER EXPLOSIONS in the United States during 1915 totaled 404. There were 132 deaths and 236 injured persons therefrom. In California 9 explosions were reported, causing 7 deaths. Tentative boiler safety-orders have been prepared for this State. The code covers the subjects of inspections, ultimate strength of material used in computing joints, minimum thickness of plates and tubes, specifications of metals used in building boilers, construction and allowable working pressures for power boilers, riveting, caulking, requirements for man-holes and wash-out holes, safety-valves, water and steam gauges, fittings and appliances, hydrostatic tests, etc. The boiler code of the American Society of Mechanical Engineers has been incorporated and made a part of the tentative orders, with a few changes affecting existing installations only.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

BUTTE, MONTANA

ZINC MINES AND PROSPECTS AT BUTTE.

The following notes and map give a good idea of the zinc possibilities of this well-known copper region:

The Butte & Superior Mining Co. (formerly the Butte & Superior Copper Co.) is hoisting 56,000 tons of 17% zinc ore per month through its Black Rock shaft. The two new shafts that are being sunk in the Black Rock claim are down 700 ft. One of them has already been raised from the 1400-ft. to above the 800-ft. level. The remaining ground will be taken out and the shaft completed from the surface to 1400 ft. by July 10. Foundations of the two new electric hoists are being prepared. It is expected to have both new shafts in operation this year. With three shafts the company will have the best hoisting facilities at Butte, and production of the B. & S. need never again suffer from inability to hoist ore or lower timber. More extensive development can also be carried on, as there will be better arrangements for transferring waste from one level to another. The mill is near the mine, and an extraction of about 93% is obtained by concentration and flotation. This recovery will be improved by changes now being made. The monthly concentrate contains 16,500,000 lb. of zinc, 340,000 oz. of silver, and 250,000 lb. of lead. The company has purchased the Mastodon claim, north of the Butte-New York ground, which is controlled by the B. & S. No development is being done in the Butte-New York claim at present. The B. & S. was the first at Butte to develop a large quantity of zinc ore. The large block-quartz manganese outcrops were worked in the early days for silver. Later, the predecessors of the present owners organized a company to explore the veins at depth in the hope of finding copper. No copper ore was found, but large bodies of sphalerite were disclosed. It then became necessary to find a satisfactory method of treating the ore. The mill feed averaged 17% zinc, and smelters would not buy concentrate in which the percentage of zinc was less than 50%. Development of the flotation process has been an important factor in the solution of the milling problem. Concentrate is still being shipped to smelters in Kansas and Oklahoma. In a recent interview, D. C. Jackson, managing director of the Butte & Superior, said:

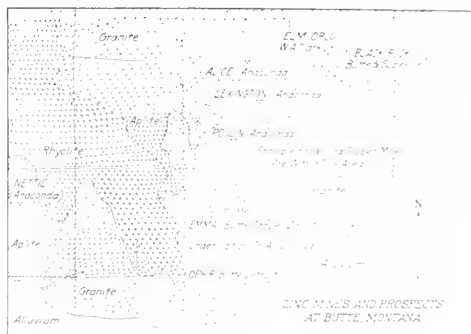

"Since acquiring the Butte & Superior property about five years ago, we have mined more than 1,250,000 tons from the upper levels and yet there is today more than double the tonnage in sight on those levels than was calculated as fully developed when we took over the property. I refer particularly to the levels above the 16th. We have done much development work on the 17th and a limited amount on the 18th; and have opened on these levels in the east end of the property, in virgin ground, more ore than was in sight in the entire property when we first started operations. Orebodies of the Black Rock claim are extending east far beyond the boundaries of the Black Rock into the Four Johns claim. So large now are the ore reserves of the Butte & Superior that the company can go on producing indefinitely at the present rate of 180,000,000 lb. of zinc annually. Butte & Superior can produce metal at less than 4c. per pound, and even should the spelter market drop back to 6c. the company can make a profit of 2c. and earn per share better than \$12 annually."

The Elm Orlu adjoins the Butte & Superior ground on the west. The same large lode extends through both properties. The ore is the same in character and grade as the B. & S. ore,

and the process of treatment is also similar. The mill is situated on the opposite side of the city and ore is handled in 50-ton railroad cars. About 800 tons of ore is hoisted daily; this quantity will be increased materially when the new electric hoist is installed. The new hoist-house is being built of steel and brick, and is practically half completed.

The Elm Orlu Mining Co. reports that it mined 200,752 tons of zinc ore, averaging \$18.52 per ton. The gross value was \$3,717,498. Expenditure included \$1,011,537 for mining, \$1,783,352 for milling, \$408,823 for transport of concentrate to smelter, and \$18,029 for construction. The net profit was \$495,757, during the year ended June 30, 1916.

The Anaconda Copper Mining Co. is making 25 tons of high-grade spelter per day by its new leaching process at Anaconda. The Lexington and Poulin mines are supplying most of the ore for this plant. The ore is graded up to 15% zinc at the mines, 180 tons being mined each day. The company has several other mines that will be called upon to furnish zinc ore for the large leaching plant that is being built at Great Falls. Occasionally cars of ore are sent from these mines to the Anaconda experi-

mental plant for testing purposes. The ore is concentrated and then leached with sulphuric acid. Some of the iron and copper goes into solution also, but the lead and silver remain in the residue. The iron is precipitated with lime and the copper with zinc dust. The zinc in solution is then precipitated by electrolysis. The zinc is deposited in spongy form. The cathodes have knobs and irregularities on them, similar to those formed in the electrical precipitation of copper; cathodes are melted and cast into molds. Concentration of the zinc ore will be done at Anaconda, and the product shipped to Great Falls for leaching. If the ore could be milled at Butte it would eliminate 50 miles of railroad haul, but there is a scarcity of water here; for that reason the large copper works of the company were built at Anaconda. The Butte & Superior is obliged to buy water from the city water system, although all of the water that is pumped from the mine is used in the mill. The Timber Butte mill, in which Elm Orlu ore is treated, gets its water from artesian wells in the flat south of the city.

The Alice is a famous old silver producer that was recently purchased, and it is now unwaterved to prospect for zinc ore. It is on the same large lode that goes through the Butte & Sa-

perior and Elm Orlu properties, and its chances of developing into a large zinc producer are considered good. The shaft has already been re-timbered to the 600-ft. level.

The Nettie, another old silver producer has been unwatered and repaired to the 500-ft. level. It is situated on the western edge of Butte, and there has been no deep development near it. The silver ore, however, will doubtless pay for re-opening the mine, which has an excellent chance to become a zinc producer when opened at depth. For over two weeks the Nettie has been making regular shipments of ore. Two ore-bins are under construction at the mine.

The Lexington mine was formerly controlled by the late F. A. Heinze. It has produced considerable silver and copper. Exploration and development of zinc ore is being carried on with satisfactory results. The Lexington is expected to be one of the big zinc producers of Butte.

The Pilot will also be a zinc producer. This fractional claim of six acres was purchased from the Pilot Butte company for \$1,125,000 cash. The claim is near the Butte & Superior, and contains both zinc and copper ore; but much of it was tied-up in the litigation that resulted in the sale of the property. There is a three-compartment shaft down 2650 ft. Mining will be resumed as soon as the new hoist is installed.

Among the Anaconda company's mines that have been copper producers in the past and in which zinc ore is now being blocked-out may be mentioned the East Colusa, Gray Rock, and Poulin. They will be in a position to hoist ore when the Great Falls works are completed.

The Emma belongs to the Butte Copper Zinc Co., but is being opened by the Anaconda company. The shaft is down 800 ft., and development is under way on that level and also at 200, 400, and 600 ft. Considerable zinc ore has already been blocked out, but it is a lower grade than that found in the northern part of Butte, and sorting will have to be resorted to if an average of 15% zinc is to be maintained. A cross-cut is being driven on the 1600-ft. level from the Gagnon, and as soon as it reaches a point under the Emma shaft raising will begin. A new hoist capable of hauling ore from a depth of 3000 ft. has been installed, and the work of sinking the shaft to meet the raise from 1600 ft. will be begun immediately. The Butte Copper Zinc Co. has 500,000 shares issued. Anaconda took over 100,000 shares at \$1 each on April 5. It has a further option on an additional 88,000 shares good until July 10, and contingent on opening of the mine to the 1600-ft. level. Including shares bought in the open market, it is surmised that Anaconda will have a majority interest in the Emma mine. The Anaconda and Butte Copper Zinc companies share equally in the profits of the Emma for five years more, which virtually gives Anaconda 75% of the profits.

The Butte Detroit Copper & Zinc Mining Co. was organized by Philadelphia, Boston, Detroit, and Canadian capital to take over the Ophir mine and mill from the Butte Central Copper Co. The Ophir produced some silver ore, and a 150-ton mill was erected to concentrate and cyanide the low-grade ore. The mill is in good condition, is on the Butte, Anaconda & Pacific tracks, and may be opened as a custom mill. The equipment consists of a gyratory crusher, Chilean mill grinding to 24-mesh, and five Deister tables. The tailing goes to Akins' classifiers and the sand product to a tube-mill, then to a cone classifier, the underflow feeding 8 Deister slime-tables. The tailing is dewatered and sent to the cyanide plant, which consists of Akins-Rotherwell continuous agitation tanks, Portland filters, and zinc-boxes. The three-compartment shaft was down 1065 ft., is now being sunk and will be ultimately opened to a depth of 2500 ft. The vein will be thoroughly explored at depth in the hope of finding zinc or copper ore. The old hoist is capable of working to a depth of 1500 ft. A station hoist will be put in at that level and later, if conditions warrant it, a new hoist will be installed. The Ophir contains a large, strong vein, and some zinc has been found on the upper levels. The Anaconda continues to develop its Douglas mine in Idaho.

PLATTEVILLE, WISCONSIN

ZINC, LEAD, AND PYRITE MARKETS IN JUNE.

Reports covering June operations in the Wisconsin zinc districts show intensified activity in all departments. A gradual lowering of the price of zinc ore in no way discouraged operators, many of whom frankly admit the day of sky-high prices for blende is over, and that the new adjustment of prices must be met with sense. Blende averaged \$88.12 per ton in May; in June the average was \$78.12, but the drop of \$10 per ton applied more nearly to the prices ruling on standard 60% concentrate. On the lower-grade products discrimination was so sharp that on the low values no offerings were submitted by ore-buyers, and the close of the month found 8000 tons of concentrate unsalable, and likely to remain a drag on the hands of independent operators until by pre-arrangement this material can be diverted to separating plants doing custom work, and the ore converted into high-grade material. The New Jersey Zinc Co., nevertheless, producing heavily from its own string of mines in the field, offered an outlet to much independent production, and the National Zinc Ore Separating Co. and the Wisconsin Zinc Co. received low-grade ores from mines not connected with these corporations. On the lower grades the following list of prices obtained: 55%, \$75; 50%, \$45; 45%, \$40; 40%, \$35; 35%, \$31, and 30%, \$25. Below 30% no buying was recorded, and there are many producers in the field whose average grade falls below this figure. Some of the higher-grade ore was carried over as well, but this was due to the belief that prices would recover, enabling operators to realize on their holdings to better advantage.

Heavy rains prevailed at all points in the field from the 10th to the 20th of the month, making ore deliveries to track almost impossible. Production was fairly well maintained, going over 40,000,000 lb. of crude concentrate, though curtailed output was manifest among producers who learned that no market was at hand for low-grade concentrate. Net deliveries out of the field to smelter direct exceeded 20,000,000 lb., the greater part of this being high-grade refined ore from the magnetic zinc ore-separating plants operating in the field. The Mineral Point Zinc Co. during the month of June shipped to smelter at DePue 5,012,000 lb. of high-grade separator product; National Separating Co., Cuba, 4,020,000 lb.; Wisconsin Zinc Co.'s roasters at Benton and Galena, 3,638,000 lb.; and Galena Refinery Co., 1,160,000 lb. The Frontier group of zinc producers shipped 1,581,000 lb. out of the Benton district to the Grasselli Chemical Company.

The wage question arose during June, several leading operators claiming that lower prices for zinc ore will surely determine a lower wage-scale. Men of all classes in the field are being well paid and no reductions have been intimated as yet, but agitation at times dwelt on this feature of the industry with prospects of probable trouble. Many new zinc mines were developed during the month. Several new power and concentrating plants were completed at different points, and given satisfactory trial-runs. More drilling machines were worked night and day than were reported a year ago when prices were so high. Strikes of rich deposits were numerous, and leasing was again in great favor, more especially in the southern districts.

Lead ore was in good demand at the beginning of the month at prices running well up to \$90 per ton. Here, too, appreciable declines were registered, and the price at the close of the month stood below \$80 per ton for 80% ore. Sales and shipments were light and a fair quantity was carried over in bins.

Shipments of pyrite were the lightest of any one month for the year, namely, 2,556,600 lb. This all came from the National Zinc Ore Separating Works at Cuba. In this instance the shipper was protected by a contract wisely drawn at a time when the fine pyrite obtained as a by-product at magnetic sep-

arating plants was in good demand. At all of the other separating plants in the field this by-product was carried over, amounting at the end of the month to millions of pounds. With prices for commercial sulphuric acid high, the lack of demand for this class of material seemed all the more inexplicable, and the general manager of one of the leading plants offered what appeared a satisfactory explanation: The tremendous increase in acid-making capacity in the United States was given as one reason, but the more plausible reason was given in high prices for spot acid, which makes it more profitable to use native sulphur from the mines of Louisiana and high-grade sulphur ore giving larger acid recovery. The acid department of the New Jersey Zinc Co. at Mineral Point increased its capacity sufficiently to yield one 25-ton tank-car daily, which was promptly routed out to the United States Steel Corp. and other Eastern outlets. At the same time the New Jersey Zinc Co. gave notice of reduced prices in zinc oxide to take effect July 1. Heavy importations of Mexican calamine ore and Canadian carbonate of zinc ore were also reported for the month at the oxide works of this company.

Producers of carbonate of zinc ore in the northern districts of the field were favored by rain, and plenty of water for outdoor washing-plants increased local production.

TORONTO, ONTARIO

COPPER AND GOLD IN MANITOBA.—DOME, HOLLINGER AND OTHER PORCUPINE MINES.—COBALT ACTIVITIES.—KIRKLAND LAKE POWER.—BOSTON CREEK.

Mining is making great progress in Manitoba this season. A rush to the Rice Lake district has set-in, and numerous companies have been organized to operate there. The copper area north of The Pas is also attracting much attention. The discovery last year of valuable copper deposits, by Jack Hammill, a well-known Toronto prospector, 110 miles north-west of The Pas, near the eastern boundary of Saskatchewan, has been taken over by the Guggenheim interests of New York, who have commenced development. They have three drills at work, and have blocked-out ore estimated at \$25,000,000. The Tonopah Co. of Nevada is operating along the same copper ridge, farther to the south-east, and opening rich ore. The mineralized ridge extends from the north-west part of the province in a south-easterly direction to Herb lake, 175 miles distant, where rich gold claims are being developed by a syndicate headed by the Hon. Hugh Armstrong, formerly provincial treasurer of Manitoba. But little prospecting has so far been done in the central part of this area, which is thought to be rich in copper. As in the case of the Rice Lake goldfields, development is much retarded owing to the lack of railroad facilities. A mining exchange is to be operated for dealing in local share issues in Winnipeg early in July; probably at a later date it will obtain facilities for trading in Eastern stocks. R. C. Wallace, provincial mineralogist, is making an inspection of the Rice Lake field; an official report will shortly be issued.

The Dome company at Porcupine made a new high record in May, milling 39,400 tons, yielding \$189,600, from an average grade of \$4.80 per ton.—The statement of the Hollinger for the 4 weeks ended May 19 shows gross profits of \$154,369, from the treatment of 33,558 tons of ore, averaging \$8 per ton. Working costs were \$3.33 per ton. Considering the heavy advances in the cost of materials, particularly explosives, the reduction of costs to this figure is considered excellent.—The Nipissing of Cobalt is taking over the Plenaunum property, in which some of its officials are largely interested.—The West Dome is improving with depth. At 250 ft. a shaft sample was taken from a width of 7 ft. 6 in., which gave \$41.20 per ton. Two other veins have been cut in diamond-drilling.—During May the Schumacher produced billion to the value of \$20,908, with net profits of \$6060. Some 200 ft. of driving has been done on one of the new veins found on the 600-ft. level. It is about 6 ft. wide and is of good milling grade.—A merger

is being arranged between the Vipond and the Huronian Belt company, which controls the North Thompson. The latter mine has good ore on four levels, but has been unable to obtain funds for the erection of a mill. It is proposed if the deal goes through to enlarge the Vipond mill to a capacity of 400 tons per day.

Silver mining at Cobalt is busy; many properties that had been closed for some time are again being worked.

Work has been started on the 65-mile transmission line of the Northern Ontario Light & Power Co. from Cobalt to Kirkland Lake. It is expected that the company will be able to deliver power to the latter plants early in September. This will give a great impetus to gold mining.

The Boston Creek Gold Mines, Ltd., capitalized at \$2,000,000, of which F. M. Richardson of New York is president, has taken over the holdings of the R. A. P. Syndicate at Boston Creek including the townsite. H. D. Symes has been appointed manager.

SUTTER CREEK, CALIFORNIA

MOTHER LODE ACTIVITIES.

Daily progress in unwatering and repairing the old Eureka shaft is 20 ft., and since the pumps began discharging about the middle of June, the water has been removed to a point 240 ft. from the surface. The shaft-timbers are found to be in a good state of preservation, many of the sets simply requiring a little timber and a general lining up. This fact, coupled with the successful operation of the pumps, accounts for the good progress being made.

The new mill at the Treasure mine began crushing on July 5 and appears to be giving good results. The plant is using Hardinge ball-mills instead of stamps. The crusher is on a high reinforced concrete frame vertically above the mill ore-bins. Below the crusher is a trommel. The trommel over-size goes to a ball-mill using large steel balls. The trommel under-size, together with the ball-mill discharge is screened on 16-mesh. The screen over-size is ground in ball-mills using small steel balls. The flow-sheet of the lower part of the mill is much like that of the Plymouth. A shaking amalgamator, Wilfley tables, Deister-Overstrom tables and Frue vanners are used. It is stated on good authority that the ore-shoot cut in sinking the shaft last year has widened out to such an extent that there will be no difficulty in keeping the plant employed steadily on good-grade ore. This mine is situated between the Bunker Hill and Fremont properties, north of Amador City.

Construction of the new Argonaut mill is well under way, a large part of the machinery having been installed and the building near completion. Much of the iron-work for this new mill has been made at the foundry of the Knight company at Sutter Creek. C. G. Cahill, one of the contractors, has been in Jackson for several days past, supervising installation of the crushing plant. While several new devices for saving gold will be introduced at this mill, the company does not contemplate the use of ball-mills nor of flotation. While the new equipment is being erected, the old 40-stamp mill east of the shaft continues to reduce some of the highest grade ore being treated in the county. The lowest levels of this mine are fully as valuable in ore reserves as the levels above.

Sinking is in progress at the Kennedy mine, good progress being made from the 375 to the 390-ft. level, vertical depth. The 100-stamp mill is in constant operation on ore extracted principally from the lower levels. The old north shaft is kept open in addition to the main east workings, thus affording a safety exit as well as better ventilation, and serving also as a supply channel for getting supplies to the working levels. Webb Smith is still superintendent of this mine, which is paying its shareholders good quarterly dividends.

J. E. Sattler, well-known in mining circles in Amador county, and in Humboldt county, Nevada, lost his life in an automobile accident which occurred on July 2 near an antimony mine in which he was interested at Unionville, Nevada.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

In its mid-year reports on the mining industry the U. S. Geological Survey makes the following remarks:

The mines and smelters of Arizona have been working at so high a pressure in 1916 that they are probably making record productions of all metals. If they continue to work at the present rate during the year they will make an output of over 600,000,000 lb. of copper, against about 450,000,000 lb. in 1915. There is much greater activity in gold and zinc mining.

There has been much greater activity in the mining industry in California for the first six months of the year, as compared with the conditions in the first half of 1915, but it has been largely in the direction of the re-opening of old properties which have been idle for years. Less gold, by \$366,000, has been received by the Mint and smelters. Aside from gold, silver, copper, and lead mining there has been thus far in 1916 a heavy demand for such minerals as chrome, tungsten, magnesite, manganese, antimony, etc., and a great many mines of this character have been opened and are shipping some to the East for the first time. There has been greater gold-mining activity in the Mother Lode counties than has been the case for a long period. Hydraulic mining has not been active outside of Trinity and Siskiyou counties, but some new mines have started up in central California. The gold-dredging industry continues in a flourishing condition. Copper mining has been very active owing to the high price of the metal.

During the first six months of 1916, according to returns received by the Survey, the output of Colorado indicates a 15% decrease in the yield of gold, little change in the production of silver, a small increase for lead, an increase of 30% for copper, and a small increase for zinc.

Unusual conditions in Idaho make it impossible to estimate accurately the lead output of the State, but shipments are being made at the rate of about 360,000,000 lb. of lead per year. There will be a correspondingly large output of silver, and a great increase in the total value of the State's output of metals. Important changes are in progress in the metallurgical industry.

The unusually high prices of metals in 1916 have stimulated mining to a marked degree in Montana, especially at Butte. At the present rate of production, there will be notable increases in the output of all metals, and a marked increase in the total value.

Mine reports received by the U. S. Geological Survey from V. C. Heikes of the Salt Lake City field office indicate that during the last six months the mining industry in Nevada has experienced one of its greatest revivals. Gold will show little increase; silver may gain; lead, copper, and zinc will record big increases.

The mines of New Mexico during the first half of 1916 show small increases for gold and silver, and appreciable increases in lead, copper, and zinc.

No changes of moment in the mining situation in Oregon are noted by Charles G. Yale, of the Survey, for the period under review. The bullion receipts of the Mint and smelters at San Francisco show that the output of gold has increased \$107,000 and that of silver 11,000 oz. In the first five months of 1916 over the output of the corresponding period in 1915. The increase in gold is due entirely to dredging operations.

High prices of metals during the last six months caused Utah producers to employ all available miners extracting ore. In some of the snow-bound camps large quantities of ore were

stored during the winter months, and when this was released to the buyers a curtailment was requested by the smelters of all producers exceeding contract limits.

The mines of Washington, for the first 6 months of 1916 promised increased production in the five important metals for the year. The industry generally seems to be in better condition than for several years past.

ALASKA

In Professional Paper 98-C. of the U. S. Geological Survey, Bertrand T. Johnson discusses the retreat of the Barry glacier near Port Wells, Prince William sound, during the years 1910 and 1914. The total retreat was 8200 and 2500 ft. respectively along the eastern and western edges.

JUNEAU

The June output of the Alaska Gold Mines was 164,800 tons of \$1.06 ore, compared with 175,215 of \$1.40 in May, and 165,930 of 94 cents in April. Recovery in June was 79.25%, with 22-c. tailing; the May extraction was 82.25%. None of the better grade ore from No. 5, 6, and 7 levels east reached the mill until June 17. On July 3 there was treated 8700 tons, a record. Shares have receded to \$16.75.

ARIZONA

An order-in-council by the Canadian government on March 25 placed an embargo on the shipment of asbestos from Canada to other than British ports, but permitted shipments to the allied countries on special license. This looked like a great hardship on American manufacturers, but it means much to the owners of asbestos mines and prospects in Arizona, says

MAP SHOWING ASBESTOS MINES AND PROSPECTS IN ARIZONA. SHADING SHOWS AREAS OF PRE-CAMERIAN ROCKS. (U. S. G. S.)

the Arizona State Bureau of Mines. In 1915 there was a great increase in the production of high-grade asbestos in Arizona, most of the lower grade in the country coming from Georgia. The embargo creates a local demand and Arizona is one of the few States that can supply it. With the opening of the

Arizona asbestos mines and the production of asbestos on a stable basis, when the embargo is removed, Arizona will be able to compete with Canadian asbestos, which heretofore has supplied the greater part of the world's supply.

GILA COUNTY (MIAMI AND GLOBE)

Churn-drilling has been resumed by the Inspiration Needles Copper Co. at Miami; eventually 7 drills will be operated. During the last week of June there was laid 4800 ft. of 2-in. water-pipe, which is connected with the pumping plant of the Miami Southwestern, and which will supply adequate water to the two churn-drills now on the ground. All lumber and material is ready for the erection of mess and boarding houses, blacksmith-shop, assay-office, and the general offices of the company.

On one day last week the Inspiration Consolidated mine produced 19,700 tons of ore in 24 hours. The Live Oak section is yielding high-grade silicious ore. Preparations are under way for construction of two more units at the mill. A Kansas City firm has the contract for steel erection.

At Globe the Old Dominion mine is producing 1200 tons of ore daily. The smelter is treating a good deal of custom ore, including some from the United Verde Extension at Jerome.

MOHAVE COUNTY

(Special Correspondence.)—Announcement has been made that Oatman is to have a custom mill. Mr. Brush, superintendent of the Gold Dust, is now in Los Angeles perfecting arrangements for the resumption of milling at this property, and it is stated that the company would employ some of its stamps on custom ore. The mill is completed, and only needs a few repairs to allow starting within 30 days. The pumping plant of the Gold Dust company will also be started if present plans materialize to bring the water from the Colorado river to the property for milling and domestic purposes.

During the past week the Big Jim mine had a visitors' day, being thrown open for inspection by the public. This property is a mine. The developments are everything that was claimed for them, particularly on the 400 and 485-ft. levels. Assays were taken right across the face of the drift at 400 ft. and gave \$658 and \$333 per ton. The superintendent, Mr. Keating, said that this orebody would average around \$400. Oatman, July 5.

For the first time since last October 20 stamps are being operated in the mill of the Tom Reed company, instead of ten.

PINAL COUNTY

In hole No. 43, 200 ft. north of No. 21, the Ray Hercules company at Ray has cut 51 ft. of 1.5% copper ore. The ore is extending north instead of to the fault. It has been definitely decided to erect a 1000-ton mill, employing flotation.

YAVAPAI COUNTY (JEROME)

The Hull and Cleopatra properties have been acquired by the United Verde Copper Co. for a large sum. The company is to increase its mine and smelter force considerably.

At 1400 ft. in the United Verde Extension the orebody has been developed by 2000 ft. of lateral work and two raises up 100 ft. A winze is being sunk 200 ft. below the level. There is blocked out 600,000 tons of 16% ore. A new two-compartment shaft for hoisting ore only, is to be sunk. The company is shipping to smelters in Arizona, at a considerable distance from Jerome, over 7000 tons of ore per month, averaging 20% copper, resulting in net profits of about \$350,000 for several months past. These earnings are due in part to the prevailing high prices for copper. Cash on hand is \$793,882; there is due from ore shipped approximately \$1,000,000, making a total of \$1,793,882.

CALIFORNIA

AMADOR COUNTY

Mining of chrome ore in the vicinity of Ione is increasing in

importance. The Julia Barilli mine is to commence shipping at an early date.

A 10-stamp mill, formerly working at the Chimax mine near Pine Grove, is being re-erected at the Pitts mine of M. Robinson in the same district.

ELDORADO COUNTY

According to Burr Evans there are over 100 miles of buried river channels, containing gold-bearing gravel, in this county. They lie at a depth of a few feet to 300 ft. below the surface. One is known as the 'Blue Lead,' the other the 'Red' or 'Grey Lead.' The deposits are from 2 to 30 ft. thick, with a grade of \$2 to \$5 per ton of gravel.

NEVADA COUNTY

It is now fairly certain that the Murchie mine near Nevada City is to be re-opened. Prior to closing 75 men were employed.—The Sultana mine, closed for two years, is now employing 15 men, in charge of A. W. Crase.

On July 4 a first-aid contest was held at Grass Valley, resulting in the North Star winning with 95.5%, followed closely by the Empire team.

SHASTA COUNTY

County assessments for this year will be \$2,000,000 greater than they were in 1915. Nearly all classes of property had increases, including \$250,000 extra on the Mammoth Copper Co.'s holdings, \$40,000 on the Mountain Copper, and \$25,000 on the Balaklala.

SIERRA COUNTY

The Alleghany district, according to the Nevada City News, is more active than for many years. During 1915 fresh capital became available for mines. The Plumbago mine is to add 5 stamps to its present 15 head, making a daily capacity of up to 70 tons.—At the Morning Glory, adjoining the Tightner, a compressor, hoist, and 5-stamp mill are to be erected.—The Sixteen to One owners are installing a 75-hp. hoist, and are considering a mill.—Joshua Hendy of San Francisco is to supply a 50-ton plant for the Twenty-One, in addition to the Lane mill now working.—An Allis-Chalmers ball-mill is in course of erection at the Irelan mine.—A compressor has been ordered for the Louise Consolidated, in charge of C. O. Jackson.—These extensions of plant will raise the daily capacity 100 tons, making a total of 350 to 400 tons, employing 300 men in mines and plants.—Results at the rich Tightner mine continue satisfactory.

The Forest City district is also to have a good year, judging by proposed work and prospects of the North Fork, Wisconsin, South Fork, Young America, Cincinnati, York-Finney, and other gravel and quartz properties.

Electric power is available throughout these districts; roads are good, labor is satisfactory, wood is abundant, and mails are regular.

TRINITY COUNTY

A 5-cu. ft. dredge, composed of parts from an old boat, is to be constructed on the Paulsen ranch, near Lewiston, by the Trinity Star Dredging Co. Fred Paulsen is a director of this concern, which includes W. F. Davis, S. Keeler, and W. B. Winston of San Francisco.

TUOLUMNE COUNTY

For the Dutch-App mines a large hoist has been ordered. An option has been secured on the J. App ranch, west of the App mine, for dumping purposes.

COLORADO

LAKE COUNTY (LEADVILLE)

Drainage of the Harvard shaft and surrounding ground to a depth of 407 ft., by the U. S. S. R. & E. Co., is nearly completed. In 24 days there was 175,000,000 gal. of water removed. A month will be required to clean-up the debris, lay

track, and cut a pump-station. Sinking 300 ft. deeper will then be started. Prescott steam sinking-pumps are to be used.

TELLER COUNTY (CRIPPLE CREEK)

(Special Correspondence).—Gold production for June, as reported by the mills and smelters, is as follows:

	Tons	Value	Gross value
Golden Cycle, Colorado City	39,000	\$17.00	\$663,000
Portland, Colorado Springs	10,000	20.00	200,000
Portland, Victor mill	18,750	2.58	48,375
Portland, Independence mill	9,696	2.16	20,943
Smelters, Denver and Pueblo	4,500	55.00	247,500
Reid-Gold Sovereign mill	700	3.25	2,275
Worcester-Rubie mill	300	4.26	1,275
Total	82,946	\$14.26	\$1,183,268

The Golden Cycle Mining & Reduction Co. paid its regular monthly dividend at the rate of 2c. per share, or \$30,000, on July 10. This makes a total of \$210,000 for the present year.

On July 25 the Vindicator Consolidated distributes \$90,000. Cripple Creek, July 1.

IDAHO

The State mine inspector, Robert N. Bell, has the following to say about the Wood River region:

"This area is also experiencing a revival of mining interest. The recent transfer of the North Star mine to the Federal Mining & Smelting Co. is an indication of vital importance to the continued progress of the mining industry of the State at this time, from the fact that the orebody of the North Star mine presents what is probably one of the most refractory combinations of mineral elements ever discovered. Its valuable metal contents are silver, lead, and zinc; but these, in important average value, are locked up with a combination of sulphur, arsenic, iron, and antimony in such a manner as to have resisted all previous efforts for their successful separation. The recent development in hydro-electric metallurgical science, which insures the successful and profitable treatment of these refractory minerals, about marks the limit in ore-treatment progress, and presents a wide field for its further application to Idaho mineral resources. Some most encouraging results of rich ore disclosures by deep development have recently been encountered in the Wood River district, and a decided revival is manifested in that region, which contains a wide distribution of promising ore prospects in great variety."

BOISE COUNTY

Operations at some of the mines in this county are briefly as follows:

The National Mining & Development Co. at Placerville, A. C. Gallup, manager, has a 10-stamp mill, employing amalgamation, concentration, and cyanidation.—The Golden Age Jr. Mining Co. at Pioneerville, T. H. Sedina, manager, has a mill treating ore by amalgamation and concentration.—The Diana Mines Co. is developing lead-copper properties.—The Washington, Sub Rosa, and Gold Coin properties, near Idaho City, were recently consolidated and taken over by Oklahoma people. Development was started on June 1. F. E. Johnesse is in charge.—The Lucky Boy at Idaho City is developing its mine and enlarging the mill, also installing power-plant. F. E. Johnesse is manager.

At the Nellie mine, Horseshoe Bend, 16 stamps are crushing, followed by amalgamation and concentration. M. E. Hopkins is manager.—Several properties at Pearl are being re-opened but there is no production at present.

BOUNDARY COUNTY

The Idaho-Continental mine, 26 miles from Porthill, has 50 men repairing the road. The new 300-ton mill is expected to be producing 60% lead and 30-oz. silver concentrate by August 1.

SHOSHONE COUNTY (COEUR D'ALENE)

Development of the Chicago-Boston Mining Co.'s property in Lake gulch, 1½ miles west of Wallace, has been so good that a 200-ton mill is contemplated.

During the first quarter of 1916, the Federal Mining & Smelting Co.'s profit from 31,844 tons of ore and concentrate shipped was \$290,890.

MICHIGAN

THE COPPER COUNTRY (HOUGHTON, ETC.)

(Special Correspondence).—The most encouraging feature about the Ahmeek mine is the increased amount of copper in the ore that comes from this northern end of the mine. This was not expected. Two stamps are crushing ore.

When the Calumet & Hecla took over the Isle Royale along with the other Bigelow properties, the officials looked on the former as questionable. Lower openings did not look encouraging, operations were conducted at an actual loss, and copper was none too high in price. Now earnings are at the rate of \$1,000,000 per month; the second dividend in 50 years has been paid, and the mine is opening well.

No work has as yet been done to re-build the Trimountain stamp-mill, as the mines' output of Trimountain, Champion, Baltic, and Lake is cared-for in the Baltic and Champion mills, which are at present saving a greater percentage of copper than expected. The re-grinding plant is working satisfactorily. The burned Trimountain mill is being cut-up and sold at better prices than expected, as a good deal of the steel is fit for use in other construction work.

It is probable that the Centennial will pay a dividend. Richer ore is being developed. The treasury is accumulating a large surplus.

Houghton, June 27.

MISSOURI

JASPER COUNTY (JOPLIN)

Zinc-ore prices were weaker last week, easing off to \$85 per ton for 60% product. The output of the Missouri-Kansas-Oklahoma district was 6290 tons of blende, 32 tons of calamine, and 937 tons of lead, averaging \$68, \$50, and \$75 per ton, respectively. The total value was \$511,915.

MONTANA

MINERAL COUNTY

The east Coeur d'Alene district in western Montana, around Salt Lake, is more active than for several years. Good developments are reported from the Last Chance, Monitor, Silver Cable, and Tarbox. A mill is planned for the Silver Cable zinc ore.

SILVERBOW COUNTY (BUTTE)

To improve ventilation on the lower levels the Tuolumne company is raising from 2600 to 2400 ft. A winze will then be sunk from 2600 ft. Daily shipments are 50 tons. The company is re-tilt-boring 700 ft. of the Butte-Main Range shaft.

NEVADA

ESMERALDA COUNTY (GOLDFIELD)

Final figures of the Goldfield Consolidated's May output give a profit of \$50,693 from 32,400 tons. Development covered 2658 ft. at a cost of \$5.59 per foot. This revealed little of importance. Net costs were \$4.66 per ton.

The estimated production of the Goldfield Consolidated company for June is as follows:

Ore mined, tons	29,000
Gross extraction	\$185,000
Operating expenses	145,000
Net realization	\$ 40,000

Interesting developments are expected at 1750 ft. in the Atlanta during the next 30 days. Drifts and raises between

the 1400 and 1750-ft. levels show large quantities of low-grade gold-copper ore that will be treated by flotation later on. Work at 890 ft. in the Jumbo Junior is also at an interesting stage, and at 1260 ft. in the Merger.

LINCOLN COUNTY

With a capital of \$10,000 the Consolidated Mining & Smelting Co. has been formed to operate in the Freiburg district, near Pioche. W. L. Leland of San Francisco is one of the largest shareholders.

NYE COUNTY

In the Jim Butler v. West End suit at Tonopah, the Supreme Court of Nevada on July 3 upheld the decision of the lower court, which was in favor of the West End. The original case concerned ore alleged to have been wrongfully extracted by the defendant. The recent judgment will be discussed in an early issue of this journal.

A report has been made on the property of the Kansas City-Nevada Consolidated Co. at Bruner by A. E. Swain of Kansas City, Missouri. The altitude is 6400 ft., and nearest railroad station is Luning, 55 miles west of Bruner. Fair wagon-roads connect. in the Paymaster claims 2585 ft. of work has been done. The vein is a fissure along a contact of andesite dike and rhyolite. The net value of reserves is \$85,162, after paying for mining and treatment of the gold ore. The Big Henry claims are of promise. Not enough work has been done in the Silent Friend claims to determine anything. The Duluth group indicates that considerable ore will be available. There is plenty of water for all purposes. A 50-ton plant, including a ball-mill, crusher, copper-plates, classifier, retort, etc., also pipe-line and other equipment is contemplated, costing \$75,000.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence).—The Mogollon Mines Co.'s clean-up for the last two weeks produced 14 bars of gold and silver bullion and 8 tons of high-grade concentrate. Ore treated in the past week was \$75 tons. The new 3-compartment shaft is now 40 ft. below the 700-ft. level and is being sunk at the rate of 2 ft. per day; it is in commission for regular hoisting from the 500-ft. level. This property is under the management of S. J. Kidder.

The Socorro Mining & Milling Co. is constructing a conveyor to dispose of tailing by elevating and fluming onto a comparatively flat area near the mill, to avoid discharging into the creek, which has caused more or less inconvenience to ranchers in the lower valleys in past years. The plant treats 230 tons of ore daily.

Surveys and measurements by Earl C. Cleaveland during the past two years on West Fork creek have demonstrated the availability of a minimum of 1000 to 1500 hp. during the dry seasons. For its magnitude this is probably the most feasible of the unappropriated water-rights within a radius of 35 miles, and if developed will supply the greater part of local power requirements. The mines for a number of years have used crude oil, freighted about 90 miles by wagon, as a source of power, at a cost of around \$150 per hp.-year. The rising price of crude oil is turning the companies' attention to the possibilities of water-power development, which will generate current at a fraction of the present cost by internal-combustion engines. It is understood the operators will contract for power at \$100 per hp.-year with any outside interests undertaking the installation.

Mogollon, June 27.

OREGON

BAKER COUNTY

The E. & E. mine at Bourne is to be examined by C. O. Lindburg for the American Zinc, Lead & Smelting Co., which holds an option on it. The property has produced gold, but was closed since the early 90's.

UTAH

Transactions on the Salt Lake exchange during the first half of 1916 totaled 24,989,039 shares, valued at \$5,293,050, against 16,867,514 shares and \$3,968,516 in the whole of 1915, and 957,064 shares and \$1,663,955 in the same period of 1915.

In Bulletin 641-A of the U. S. Geological Survey, Heath M. Robinson discusses the ozokerite (mineral wax) deposits in central Utah (Utah and Wasatch counties). This mineral was also described in this journal of June 17, by L. O. Howard. The quantity of ozokerite available for future mining in the Utah field can hardly be estimated. The length and thickness of the fissured and fractured zones containing ozokerite are variable, even within short distances, and for areas beyond the limits of prospected ground no quantitative estimate can be made with safety. Many of the prospects and mines, however, showed ozokerite in place, and the fact that it is irregularly distributed should encourage more thorough prospecting. The price is now up to 40c. per pound.

The Wasatch Ozokerite Co.'s new mill at Soldier Summit is

MAP OF UTAH SHOWING THE OZOKERITE FIELD.

now operating satisfactorily, according to A. G. Burritt, a local engineer who recently visited the property. The company is making mineral wax.

JACOB COUNTY

The Eagle & Blue Bell mine, now producing only 50 tons of ore daily on account of congestion at smelters, is to sink its shaft from 1700 to 1850 ft.—The Colorado Consolidated shaft is down 1300 ft., the rate being 5 ft. daily.—A two-compartment shaft is to be sunk at Homansville or East Tintic by the Chief Consolidated company.

The Dragon Consolidated is shipping 400 tons of iron ore per day, divided among the A. S. & R., I. S., and U. S. S. R. & M. companies' smelters in Utah.

SALT LAKE COUNTY

In the American Fork district the Pacific company is to erect a 60-ton mill. Mr. Doeltle is manager.

At the Utah Metal & Tunnel Co.'s property at Bingham there are 7 sets of leases working in 7 old adits. The company's profit during the first half of 1916 was over \$600,000 copper. Ore is being milled and shipped to smelters, while lead ore is also shipped.

SUMMIT COUNTY (PARK CITY)

June shipments from all mines totaled 5589 tons, and 14,322 tons for 6 months.

Dividends paid on July 1 were \$187,500 by the Silver King Coalition, \$120,000 by the Judice Mining & Smelting, and \$63,750 by the Silver King Consolidated, a total of \$371,250.

WASHINGTON

OKANOGAN COUNTY

The new manganese mine near Omak has been leased by the Millroy company of Tacoma. One shipment contained 20% metal.

STEVENS COUNTY

At a depth of 242 ft. below the outcrop, No. 2 'chimney' has been cut in the Electric Point mine near Northport. For 18 ft. the galena averaged 75% lead, also mixed carbonate and crystals with 50% lead. Silver is over 20 oz. per ton. The remarkable feature of the development is the presence of so much crystallized lead in the carbonate ore of No. 2 chimney as to raise the grade from an average of 22% in the first chimney to 50% in the newly opened orebody. Galena is being shipped to Trail.

The old Germania tungsten mine near Springdale has been sold to German interests, with W. Von Scheek to be manager. Development has cost \$500,000, including the 200-ton mill, etc., which was dismantled recently. Litigation closed the property, and it never produced.

An effort is being made to revive the old Spokane Belle silver mine, 35 miles north of Spokane, near Clayton, one of the oldest mineral locations in this part. E. H. Belden, of Spokane, sole owner of the property, is arranging to form a syndicate to finance further development.

CANADA

BRITISH COLUMBIA

Net earnings of the Galena Farm Mining Co., near Silverton, were \$40,000 in May. From the 100-ton mill shipments aggregated 759 tons of concentrate that averaged 46.5% zinc and 20 oz. silver, which netted \$25 per ton, and 237 tons of concentrates averaging 67.3% lead and 66.1 oz. silver, netting \$125 per ton.

During 158 days in 1915 the British Columbia Copper Co.'s smelter at Greenwood treated 122,514 tons of ore. The Mother Lode mine contributed 105,085 tons, averaging 0.8746% copper, 0.037 oz. gold, and 0.21 oz. silver. The sulphur content was 3.15%. The metal output was 1,734,385 lb. of copper, 23,003 oz. of silver, and 5417 oz. of gold.

The new sulphuric-acid plant of the Consolidated Mining & Smelting Co. at Trail, which will produce acid as a by-product from smelter fume, the first plant of the kind to be erected in British Columbia, is in operation. The present daily output is 10 tons.

ONTARIO (COBALT)

The Buffalo company is to treat its own concentrate instead of shipping this product. A roasting-furnace and dust-chamber will be erected. The concentrate, 30 tons daily, is to be given a chloridizing roast. A large saving in freight and treatment charges will follow this installation. During its financial year ended April 30, 1916, the Buffalo Mines Co. produced 37,152 tons of ore, yielding 705,055 oz. of silver by all processes. The revenue was \$524,973, and operating expenses \$266,206. Reserves of ore in the mine and on dumps amount to 18,000 tons, averaging 18 oz. per ton. There is awaiting treatment 300,000 tons of tailing containing 1,600,000 ounces.

At Cobalt the Nipissing refinery was recently damaged by fire. The machinery was not badly damaged. On June 17 cash in bank amounted to \$965,534; bullion in transit, \$552,352; and ore and bullion on hand at the mine, \$330,026; a total of \$1,858,912. A dividend of 5% is payable on July 20.

KOREA

Details of the Oriental Consolidated company's April results are just to hand. The plants treated 25,142 tons for bullion valued at \$143,701. The Taracol and Maibong mills recovered 93.6% and 92.4% respectively. Tree planting for the season is over, the work including 175,000 acacias, larch, and pines.

PERSONAL

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

NEWTON B. KNOX was at Denver last week.

F. W. BRADLEY was at Kellogg, Idaho, this week.

G. G. S. LINDSEY has returned to Toronto from China.

WILLIAM W. MEIN is expected shortly in San Francisco.

EDWARD H. BENJAMIN is president of the Bohemian Club. HOWARD W. MOORE is engineer to the Calaveras Copper Co., at Copperopolis.

F. L. SIZER is making an inspection of mines in the Chloride district, Arizona.

BEN. B. LAWRENCE, who was in Oregon last week, is expected in San Francisco.

NELSON DICKERMAN is in New Mexico, but will be in San Francisco at the end of July.

J. A. L. HENDERSON, from London, passed through San Francisco on his way to Los Angeles.

OTTO SUSSMAN of New York was recently at Wallace, Idaho, inspecting the Interstate-Callahan mine.

HARRY HEINE and G. L. CLARK are at the Porcupine Vipond mine, and H. H. LAVERY is at the Dome.

R. W. SCHULTZ, formerly with the Mond Nickel Co., has joined the staff of Minerals Separation, Ltd.

HERBERT W. GEPP, of Broken Hill, Australia, is visiting the Bully Hill smelter, Shasta county, California.

ROSS K. MACARTNEY has been appointed manager for the Rhodesia Broken Hill company, South Africa.

G. A. DENNY is acting as technical advisor to the General Mining & Finance Corporation at Johannesburg.

PERRY MARSHMAN, manager of the Swansea Vale zinc plant, in South Wales, is visiting zinc smelters in this country.

T. LOUIS WELF has been appointed superintendent for the Gold Reed Mining & Milling Co., at Oatman, Arizona.

FRANK MERRICKS has been elected president of the Mining & Metallurgical Club (London). BEDFORD MCNEILL is vice-president.

J. B. TYRRELL, of Toronto, is spending some time in British Columbia. His address while there is the Vancouver hotel, Vancouver.

W. A. PAINE, president of the Copper Range Consolidated, and his son, F. WARD PAINE, are visiting in the Michigan Copper Country.

CLYDE T. GRISWOLD is heading the Associated Geological Engineers' field parties for extensive examinations in southwestern Oklahoma.

ROBERT MARSH, JR., general mine superintendent for the Nevada Consolidated Copper Co., is in military training camp at Monterey, California.

T. H. GILL, of the North Star company's Champion mine at Nevada City, has temporarily joined the staff of the California Accident Commission.

GILBERT RIGG, formerly with the New Jersey Zinc Co., has been appointed consulting metallurgist in zinc smelting to the Broken Hill Associated Smelters, in Australia.

JOSEPH H. WHITE, sanitary engineer for the U. S. Bureau of Mines, has resigned to take a similar position, including welfare work, with the Braden Copper Co. in Chile.

JOHN D. RYAN, president of the Anaconda Copper Mining Co., has been taking a holiday with his family at their old home in the Michigan Copper Country. He is now in San Francisco.

JAMES E. DAVIS, formerly superintendent of the Central Eureka mine at Sutter Creek, has been appointed superintendent for the Calaveras Consolidated Mining Co., at Melones, California.

THE METAL MARKET

METAL PRICES

San Francisco, July 11.

Antimony, cents per pound	15
Electrolytic copper, cents per pound	28.50
Pig lead, cents per pound	7.99-7.75
Platinum: soft metal, per ounce	\$79
Platinum: hard metal, 10% iridium, per ounce	\$74
Quicksilver: per flask of 75 lb.	\$83
Spelter, cents per pound	15
Tin, cents per pound	43
Zinc-dust, cents per pound	29

ORE PRICES

San Francisco, July 11.

Antimony: 50% product, per unit (1% or 20 lb.)	\$1.00
Chromite: 40% and over, f.o.b. cars California, per ton	12.00-14.00
Manganese: 50% product, f.o.b. cars California, ton	12.00-20.00
Magnetite: crude, per ton	5.99-10.00
Molybdenum: 50% and over, per pound	0.60-1.15
Tungsten: 60% WO ₃ per unit	25.00-35.00

Potash bulletin of the U. S. Geological Survey is now available. It contains 38 pages of useful information.

Recent tungsten (wolframite) concentrates from the Wasp No. 2 mine, South Dakota, were settled at the following rates.

Date	% WO ₃	Price per unit	Price per ton
June 1915	48.24	\$7.99	\$281.09
August	47.20	10.59	285.60
October	44.93	27.50	2,748.94
December	48.08	51.54	1,235.57
March 1916	62.02	82.00	5,085.64
"	35.34	82.00	2,897.88

In 11 lots of 208 tons the value was \$243,875.

EASTERN METAL MARKET

(By wire from New York.)

July 11.—Copper is neglected and prices are nominal; lead is quiet with re-sellers cutting prices; spelter is also neglected, but the bottom is near.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date	Average week ending
July 6	63.37
" 7	62.75
" 8	62.00
" 9 Sunday	60.90
" 10	62.00
" 11	62.00

Monthly averages

1914.			1915.			1916.			Averages								
1914.			1915.			1916.			1914.			1915.			1916.		
Jan.	57.58	48.85	56.76	54.90	47.52	
Feb.	57.53	48.45	56.74	54.35	47.11	
Mch.	58.01	50.61	57.89	53.75	48.77	
Apr.	58.52	50.25	64.37	51.12	49.10	
May	58.21	49.87	74.27	49.12	51.88	
June	56.43	49.03	65.94	49.27	55.34	

The past week's quotations indicate sudden fluctuations, probably due to speculation. On page 97 of this issue are some interesting notes on silver, rather 'bullish' in tone.

Exports of silver from San Francisco during the first half of 1916 amounted to \$241,388 as coin and \$4,209,105 as bullion.

The West End Consolidated at Tonopah is paying 100¢ per share.

TIN

Prices in New York, in cents per pound.

Monthly averages							
	1914.	1915.	1916.		1914.	1915.	1916.

Eastern Metal Market

New York, July 5.

All the metals are dull, and if quotations are not lower in each case, they at least are weak.

Copper prices are fairly well sustained, considering the stagnation of the market.

Zinc has continued to decline steadily.

Lead is irregular and quiet.

Tin is lower, and a dull month is predicted because of the large supply and heavy deliveries into consumption.

Antimony continues on the downward grade.

Aluminum is easier.

With the steel mills domestic business is lighter, as heretofore mentioned, but specifications on the books are enough to insure activity to the end of the year and therefore maintained prices, or at least, prevent substantial declines. Forgings for large shells constitute a large item with the larger mills. The total pig-iron production in June was 3,211,588 tons, or 107,053 tons per day, against 3,361,073 tons in May, or 108,422 tons daily. Furnaces are showing the effects of their forced operations. There is a heavy export demand for steel-making iron. Iron and steel exports in May totaled \$72,918,000, against \$26,536,000 in the same month of 1915. The total for 11 months ending May was \$545,418,000, compared with \$279,000,000 for the record period ending May, 1913.

Munitions' makers who have finished their contracts are beginning to offer their machine-tools on the open market, but not to a degree which injures the industry.

COPPER

In the past week the situation in copper has undergone little change, and interesting features are almost entirely lacking. There is little demand, in fact, representatives of the trade say they do not see how the market could be more dull. Despite the quiet, prices are fairly well maintained, a situation which is attributed to the sold-up condition of the larger producers. As a matter of fact near-by copper is not nearly so easy to obtain as some of the daily papers assert. The nominal quotation for prompt electrolytic is 26.50c., cash, New York, or about 26.37½c., 30 days, delivered, while Lake is nominally quoted at 27c., cash, for prompt. Just a trifle better tone is apparent, which is based on the present drive of the Allies against the Germans. It is argued that enormous quantities of ammunition are being used, and that a fresh demand for copper may be created. Exports in June reached the excellent total of 35,753 tons, a figure which has been exceeded in only one month since the beginning of the War. The London market is weak. On June 30, when the last cable quotation was received, electrolytic was quoted in London at £132.

ZINC

Quotations for this metal are weak the world over. In New York and at St. Louis prices have continued to decline, and to do so without exciting the interest of consumers. Today prompt zinc is easily obtainable at 11c., New York, and this price probably could be shaded. It is equivalent to 10.25c., St. Louis. July delivery can be had at 10.50c., St. Louis, and August at 10c. At London, July 3, the market dropped £10 to £51 for spot, and £8, to £45, for futures. It is difficult to tell just why the market continues to decline so steadily, although a good guess would be that new producers are eager to get business, while the old ones are determined to retain their hold on the field. Consequently there is no maintenance of prices, and the consumers, aware of the situation, can afford to stand by and see just how low prices will go. The market is being made by offerers. Exports last month totaled

4275 tons. The quotation for sheet zinc is 18c., f.o.b. smelter, carload lots.

LEAD

Reports of the actual condition in lead are contradictory, inasmuch as some sellers declare they are doing a fair business, while others say there is nothing doing. One thing is certain, and that is the recent decline in the market was checked by some export buying, including one lot of perhaps 5000 tons for Russia. Since then the New York quotation of independent sellers has been 6.85c., and that at St. Louis about 6.65c., although a good sale involving shipments covering the last half of the year was made at substantial concessions from these prices. The A. S. & R. Co. continues to quote 7c., New York, and 6.92½c., St. Louis. The London market is weak at a price equivalent to 6c., New York, and makes further export business improbable. Lower domestic prices are indicated. Exports in June totaled 2029 tons.

TIN

The market has continued dull, and prices are lower. Aside from these basic features, interest is centred in the June statistics. These showed that the arrivals of the month totaled 5695 tons, and that the deliveries amounted to 6398 tons, thereby demonstrating that consumption is heavy. Of the deliveries, 2198 tons came from the Pacific coast, a large part of which probably was Chinese tin. The heavy deliveries indicate a slow month for the brokers. The total of American deliveries in the past six months was 28,621 tons, which compares with 22,217 tons in the first half of 1915, an increase of 6404 tons. In stock and landing, June 30, was 3963 tons, against 2468 tons, May 31, an increase of 1495 tons. The London market is weak. The New York quotation was easy at 38.87½c., July 3, but despite this low price, business could not be done.

ANTIMONY

This metal is demoralized; the only question is where the decline in price will stop. It can be bought today at 16c., per lb. for spot, and 15c. for futures, and it is asserted that a firm offer considerably below these figures would not be spurned. Should there be an influx of shrapnel-shell orders, the market would take a sharp turn upward, but such orders are not considered probable.

ALUMINUM

The quotation for spot No. 1 virgin aluminum, 98 to 99% pure is lower at 60 to 62 cents.

ORES

Antimony: The quotation is unchanged and nominal at \$2 per unit.

Tungsten: In a general way the situation is unchanged and the quotation remains unchanged at \$30 to \$35 per unit. No business of importance has been done, although there are several live inquiries. Some of these come from sources new to the sellers. The Tungsten Products Co., Boulder, Colorado, has purchased a 5-ton Rennerfelt electric furnace, 150-kw. for making ferro-tungsten. One 3-ton electric furnace, and one 6-ton, have been purchased by other parties, also for the manufacture of ferro-tungsten.

Melting brass and bronze with the electric furnace is not new in Europe, but has not been done very successfully heretofore in the United States. Two Rennerfelt electric furnaces have just been sold by Hamilton & Hansell, New York, for melting these alloys. The Gerline Brass Foundry Co., Kalamazoo, Michigan, has bought a 3-ton furnace for bronze, and the Titanium Alloy Mfg. Co., Niagara Falls, New York, has bought a similar furnace, also for bronze.

COMPANY REPORTS

MIJNBOW MAATSCHAPPIJ REDJANG-LEBONG

This silver-gold producing company's property is in Sumatra, Dutch East Indies, a few hours from Singapore. The report of the general manager, F. C. Frey, is for the year 1915.

Development amounted to 1675 metres (5508 ft.). The ore-body was cut on No. 7 level of the middle shaft during May, but water makes further work slow. Possibilities of opening ore at depth are sufficiently encouraging to warrant sinking the shaft to No. 10 level; but with the electric power available this cannot be done yet. Drought interfered with operations last year. Two new power schemes have been investigated. Mine ventilation was improved. Old stopes were filled with 48,630 tons of waste. Ore reserves are estimated at 220,000 tons, assaying \$8 gold and 2 oz. 8 dwt. silver per ton. During

MT. LYEELL MINING & RAILWAY CO.

The report of Robert Sticht for the half-year ended March 31, 1916, states that the supply of labor for the mines was in sufficient; 1180 ft. of development was performed the Mt. Lyell pyritic orebody was opened for 50 ft. on No. 2 level averaging 10 ft. wide, which is considered to be a portion of the lowest extremity of the deposit, favorable results attended prospecting at 1200 ft. in the North Lyell mine; ore reserves in the Mt. Lyell mine are 1,815,505 tons assaying 0.53% copper, 1.96 oz. silver, and 0.04 oz. gold; in the North Lyell 1,110,341 tons of 0% copper, 1.33 oz. silver, and 0.005 oz. gold; in the South Lyell 464,352 tons of 0.4% copper, 0.2 oz. silver and 0.04 oz. gold; the flotation plant was started on February 17, and in 132 hours treated 1475 tons of Lyell Comstock ore of 3.25% grade for 444 tons of 8.83% concentrate, a satisfactory result the smelter reduced 170,992 tons of ore, (90,375 from the Mt. Lyell and 59,497 from the North Lyell), flue-dust, matte, slag etc.; converters produced 6,539,840 lb. of copper, 4682 oz. of gold, and 200,771 oz. of silver; the cost of producing blister-copper in Tasmania was \$4.56 per ton of ore; investigations were made on the recovery of sulphur from the blast-furnaces; and the hydro-electric power scheme gave complete satisfaction.

Owing to the good season throughout Australia the super-phosphoric works at Melbourne, Adelaide, and Fremantle produced a large quantity of fertilizer.

The revenue from metals, chemical products, and railroad traffic totaled \$426,693 (\$2,050,000). The 20th dividend absorbed \$80,575, making \$3,956,492 to date. Taxes amounted to \$65,951 (Federal, State, and War). The company has options on the Hercules, Tasmanian Copper, and Primrose mines on the west coast of Tasmania. These ores are complex, and are being tested by flotation at Broken Hill.

An average of 2.61 blast-furnaces was kept up. The coke works in New South Wales supplied the coke necessary. Rainfall at the mine was 35.67 inches on 112 days. Production to date is 142,676 tons of copper, 11,521,543 oz. of silver, and 341,079 oz. of gold.

MAP OF THE DUTCH EAST INDIES.

The Redjang Lebong mine is in Sumatra, which is also an oil producer. Banks and Billiton islands and the Malay Peninsula are large tin producers, also part of Sumatra has zinc-lead mines, also ruby deposits and oil. In Borneo are oil, dredging areas, and gold lodes. The Celebes have copper and gold mines. In the Philippines are well-known lode and dredging properties. New Guinea has mining possibilities.

the year 13,094 tons of \$9.50 gold and 2 oz. 17 dwt. silver were was recovered from old stopes. This was formerly regarded as unprofitable. The value of the ore gets less with depth.

There were 70 stamps operated 293 days, and 6 tube-mills 248 days, crushing 83,329 tons of ore. This averaged \$8.78 gold and 2 oz. 15 dwt. silver per ton. There was no amalgamation done. Pulp was classified into 67.5% for slime and 32.5% for sand treatment. The slime plant gave 94.83% gold and 84.59% silver recovery, and the sand plant 86.99% gold and 75.64% silver. Cyanide percolates with ease through sand averaging 80% passing 200-mesh. The total extraction of value was 90.69%. Metal recovery was 34,204 oz. of gold and 186,678 oz. of silver, worth 1,951,500 florins (1 florin = 40 cents). The cost was \$6 per ton. Dividends absorbed 431,250 florins or \$172,500. Employment was given to 45 Europeans and 1747 colored people.

Among the experiments done during the year were included how to economize in cyanide and zinc, also the local treatment of slag.

McINTYRE PORCUPINE MINES

The financial year of this Ontario company ended on March 31, 1916. The report of the manager, R. J. Ennis, contains interesting notes and three geologic plans. The property adjoins the Hollinger, Schumacher, and Plenaurnum mines, and includes most of Pearl lake.

Development amounted to 6584 ft., also 5787 ft. of diamond-drilling. Payable orebodies are not found in the quartz-porphry of No. 1 shaft. Those at No. 4 are confined to an area of two acres of basaltic-schist. Ore reserves are estimated at 201,920 tons, averaging \$11.12 gold per ton. Mining cost \$2.5116 per ton.

The mill treated 105,758 tons, assaying \$7.709 per ton, with 95.6% recovery, at a cost of 96.18c. per ton. The ball-mill is entirely satisfactory. The plant now has a capacity of 450 tons per day.

The year's revenue was \$775,821, of which \$327,524 was profit. All costs were \$4.2783 per ton. The balance at credit is \$383,050.

BOOK REVIEWS

MECHANICAL ENGINEER'S HAND BOOK. By Lionel S. Marks. P. 1836. Index. McGraw-Hill Book Co., New York. For sale by MINING AND SCIENTIFIC PRESS, San Francisco. Price, \$5.

This work has been adapted from Hütte, translated and revised by a large staff of specialists on various engineering subjects. Modifications from the original text have been made in order to adapt the subject matter to American use and conditions. It is, however, not merely a translation, as the greater part of the book, especially those portions dealing with engineering practice, is entirely new. Thirteen specialists prepared the text on the properties of engineering materials, while that on automobiles, aeronautics, illumination, patent law, cost-accounting, industrial buildings corrosion, air-conditioning, fire-protection, and prevention of accidents, has each been prepared by separate writers. Mr. Marks and his collaborators have done a splendid work in presenting this reference work for the benefit of the engineering profession.

MICROSCOPICAL DETERMINATION OF THE OPAQUE MINERALS. By Joseph Murdoch. P. 165. Ill., index. John Wiley & Sons, Inc., New York. For sale by MINING AND SCIENTIFIC PRESS. Price, \$2.

Three-quarters of this book consists of tables for the classification and identification of minerals, arranged with thumb indentations. The first quarter of the book treats of the history, development, and technique of the microscopical determination of minerals. In a preface, L. C. Gratton of Cambridge, Massachusetts, remarks: "This scheme for determination of opaque minerals does not require a specialized training for its intelligent use. Practically the only requirement is to follow the simple directions. The entire scheme may be mastered by anyone possessing common sense and a good eye." The problems that were solved in the Harvard laboratories by this method of investigation include: the relation of gold and silver in ores as affecting choice of treatment; the condition of fine metal lost in mill tailing and in slag; the effect of roasting and leaching of sulphide-bearing tailing; the character of furnace matte; geological problems involving metal in pulp from drill-holes.

THE ENGINEER IN WAR. By P. S. Bond. P. 176. Ill., index. McGraw-Hill Book Co., Inc., New York. For sale by MINING AND SCIENTIFIC PRESS. Price, \$1.50.

This book is a revision and amplification of a series of articles that appeared recently in the *Engineering Record*. It is addressed mainly to the civilian engineer who is desirous of learning at least a little concerning the part he may be called upon to play in time of war. Any attempt, however, to write a complete treatise on military engineering is expressly disclaimed. The first two chapters deal with the military policy of the United States and with the general duties of the military engineer. The various branches of military engineering are then discussed, emphasis being placed upon the fact that, whereas the civil engineer in general aims to build a permanent structure at the lowest possible cost, the military engineer must build, in the least possible time and at whatever cost may be necessary, a temporary structure that will be serviceable. A chapter is devoted to the mobilization of material resources along the lines of the industrial preparedness census now being taken. The final chapter contains suggestions regarding ways in which engineers and contractors may fit themselves for military service in time of need, suggestions that will be much heeded by many engineers.

MINING DECISIONS

MINING CONTRACT—ABANDONMENT

A mining contract obligated the option-holder to install certain machinery and carry on development work. Abandonment of work for a period of six months was to operate as a forfeiture. Held, in a suit to quiet title and forfeit contract, that the obligation to commence work began with the signing of the option, and not after the machinery was installed. Failure for more than a year to install the agreed machinery was sufficient grounds for forfeiture of the contract.

Barandun v. Barandun Mining & Milling Co. (California), 156 Pacific, 473. March 8, 1916.

OIL LANDS CLAIMED BY UNITED STATES—JURISDICTION

A Court of Equity has jurisdiction to grant an interlocutory injunction in a suit brought by the United States to enjoin the taking of petroleum from land which the Government claims to own, and which constitutes its chief value, particularly where the United States owns adjacent oil-lands which might be drained by the defendant's alleged illegal operations.

El Dora Oil Co. v. United States (California), 229 Federal, 946. December 4, 1915.

OIL TRESPASS—DAMAGES FOR CONVERSION

One who wilfully and intentionally takes ore, timber, or other property from the land of another must respond in damages for the full value of the property taken, at the time of the conversion, without any deduction for the labor bestowed or expense incurred in removing and preparing it for the market; but if he commits the wrongful act unintentionally, or by mistake, or in the honest belief that he is acting within his legal rights, the measure of liability is the value of the property taken, less what it costs to produce it. This rule applies to trespass on oil-lands, and additional damages may be allowed for the withholding of compensation to the rightful owner.

Bryson v. Crown Oil Co. (Indiana), 112 Northeastern, 1. March 31, 1916.

PETROLEUM WITHDRAWALS—EFFECT OF

The proviso of the act of June 25, 1910, saving from the force and effect of petroleum withdrawals the rights of bona-fide occupants or claimants of oil or gas-bearing lands who at that date were in the diligent prosecution of work leading to discovery of oil or gas, contemplates work of actual development with a view to discovery of oil or gas, and does not include efforts to secure capital to carry on work of development or to secure a purchaser to take over the property. An order of withdrawal has the same force and effect as an adverse claim asserted by any qualified person; and if a claim within a withdrawn area would have been subject to peaceable entry by an adverse claimant because of lack of diligence on the part of the prospector, it would be defeated by the order of withdrawal. Where an application for patent under the mining laws is based on a certain specified location, and proceedings by the government are instituted against the same, charging that some of the alleged locators are without interest, the applicant will not be heard, in the absence of publication and all other processes attendant upon an original application, to assert that in fact he bases his application on a different location of the same land.

Pacific Midway Oil Co. et al. (Land Department), 44 Land Decisions, 420. April 21, 1915.

EDITORIAL

T. A. RICKARD, *Editor*

IF prosperity be measured by the purchase of luxuries, then the importation of diamonds and other precious stones indicates it unmistakably. In the fiscal year ending June 30 the port of New York admitted \$44,887,826 worth of precious stones, as against \$14,760,847 in 1915 and \$33,183,735 in 1914.

IN our issue of July 8 we criticized the mid-year summary of mining progress issued by the Geological Survey as being too general in its statements. Since then we have received the résumé prepared by Mr. Charles G. Yale covering mining operations in California and take pleasure in acknowledging that it is an admirable précis of information prepared by a trained journalist. In reports of this kind it is necessary to give live details as well as embracing generalities. To do so effectively in a modicum of space requires something more than a bundle of statistics.

OUR friend the editor of the Canadian Mining Institute bulletin has the saving sense of humor that makes the wheels of life run sweetly. What he had to say, in the July issue, on "the delicate subject" discussed in our issue of July 1 is excellent. That "all the really important mining undertakings in the United States are directed by 'Canadian engineers'" is manifestly true because to the Canadian only the undertakings so directed are of real importance. Joking apart, it is remarkable what a splendid group of metallurgists has been given to this continent by McGill University.

WE find it necessary to refer again to the Canadian Mining Institute's July bulletin, because it contains an article by Mr. David H. Browne, or what he explains as the joint effort of himself and his friend Mr. Gilbert Rigg, who is now on his way to Australia, and therefore unable to disclaim the responsibility. It reads a good deal like our friend in New York, so we shall presume that he and Mr. Rigg are equally thoughtful and sympathetic. Truly, such a splendid lay sermon is not often to be found in a technical publication, and we thank the editor, Mr. H. Mortimer-Lamb, for it. Canada has indeed found herself in this war; she is no longer merely a population, colony, or dominion, but a Nation.

ZINC continues to cheapen. Undoubtedly the estimate of production published by the U. S. Geological Survey scared the market, for the decline in price followed immediately thereafter. The forecast of an output this year 130% higher than that of 1914 was enough to make the producers of spelter think furiously and dejectedly.

Even though this official estimate erred in exaggerating the probable production, it had the effect of a loud warning to the careless optimists in the metal market. If the Government forecast be discounted by 25%, there still remains more than enough zinc for any visible demand. The price has fallen to 9½ cents per pound, as compared with 17½ cents in January.

DISCUSSION this week starts with some interesting comment by Mr. Courtenay De Kalb on Mr. Probert's articles on "Superficial Indications of Copper." Mr. De Kalb dwells upon the part played by gases of magmatic origin in producing the alteration of mineralized rock. Mr. Thomas Marshall, now with the North Star Mines at Grass Valley, recounts his early acquaintance with the discoverer of cyanidation and gives several interesting notes concerning the first application of the process in California. Mr. Loring Hanson corroborates Mr. Berry's description of the earthquake in Nevada. Mr. Harold French writes as a mining engineer to suggest a new scheme of prospecting, giving details of the cost involved.

QUICKSILVER has been the sport of artificial conditions, as our readers are aware. On another page we publish a timely summary of this branch of the mining industry as issued by the U. S. Geological Survey. The supply of quicksilver in this country has been coming from a few mines; in California the New Idria has contributed 75 to 80% of the output during the last decade, and in Texas the Chisos mine, in the Terlingua district, is the only important producer. In California, the New Almaden and Guadalupe mines, which are contiguous, are important, and quite recently the Oceanic has come into prominence. In Nevada, the output comes from a number of small mines. A discovery of high-grade cinnabar ore has been made recently near Morton, in Washington.

REFERRING to the subject of a national engineer reserve, discussed under "Preparedness" in our issue of June 24, we are glad to state that the legislation authorizing the organization of an Engineer Reserve has been enacted by Congress and has become effective as from July 1, 1916. This Army Reorganization Act contains provisions for the formation of an Officers Reserve, including engineers. The War Department is issuing an invitation to the engineers of the country to apply for commissions in the Reserve Corps of Engineers in the several grades from Second Lieutenant to Major, and any of our readers desiring information concerning the

method of procedure required to secure a commission should apply to the secretary of their respective national engineering society.

SCHEELITE in gold ore may make the ore more valuable for the tungsten than for the gold. Hand-picking the scheelite and treatment of the ore for gold is the usual procedure, as noted by Mr. A. D. Cox in our issue of January 8 describing practice at the Union Hill mine, Grass Valley. Fine crushing would usually make it impossible to save both the gold and scheelite, as the latter is friable and makes a floury mess. In this issue we publish an article describing the method at gold-scheelite mines in the South Island of New Zealand. The ore is crushed to 30-mesh, after being hand-picked, and the coarse gold is saved on copper plates. The pulp is classified before going to Wilfley tables, where the scheelite is separated, the sand being cyanided. As much as 55% pyrite may accompany the 35% of scheelite and the 2½ oz. gold in the concentrate. Roasting of the concentrate follows, with magnetic separation.

THE notorious I. W. W. is making trouble at the iron mines of the Mesabi range in Minnesota. The initials 'I. W. W.' officially mean 'Industrial Workers of the World,' and unofficially 'I Won't Work.' In Minnesota, agitators from Chicago found support from only a small minority. Foiled in an attempt to call a strike, the disturbers threatened the life and property of the miners, forcing them to stop work. It is charged that they intimidated, through the wife or other women of a household, that the husband or brother would be killed, or that the dwelling would be burned, unless the men of the family stopped work. Rather than live in a state of terror, many families quietly left the district and found employment elsewhere. This constitutes neither a strike nor a lock-out; it is plain terrorism. As the *Iron River Reporter* exclaims, "Think of it! In these United States of America, where men claim the greatest freedom of any nation on earth, a few professional agitators may invade a peaceful community and drive workmen from their toil and homes." An interesting side-light was thrown on the Mesabi strike when a particular agitator from Chicago communicated to the mine-managers that if they wanted trouble stopped, they could "make arrangements" with him. Even this is nothing new. The worker has ever been the victim of irresponsible anarchists, for that describes the man that disregards all the laws governing an organized community.

FROM the lengthy report of the Zinc Corporation meeting appearing in the *Financial Times* we gather that a concerted attack has been made on the management of that important company's affairs by Messrs. F. A. Govett and H. C. Hoover. At the meeting Mr. Govett, as chairman, made a full and frank statement; indeed he is habitually outspoken and ready to take shareholders into his confidence, to a degree exposing him to the charge of egoism. But it is a good fault, partic-

ularly at a time when the difficulties due to the War have caused complications in the company's affairs and offered a chance for malicious innuendo. In his speech he disclosed the extraordinary diversity of the company's financial participations and promotions. Business of this kind cannot be conducted in public view; much of it must be kept secret from competitors; therefore, it is essential that those in control hold the complete confidence of the shareholders. If the latter are unwilling to place such confidence in their trustees, the business becomes impracticable. The necessary dealings and interplays of finance must be taken on good faith if anything effective is to be done. We do not know why Messrs. Govett and Hoover should not be supported in their management; it seems to us that the Zinc Corporation would have been on the scrap-heap long ago if these two capable men had not co-operated strenuously to re-organize and administer it during bad times. The intrusion of an old feud is deeply regrettable and can do no good to anyone. Leaving this unpleasant phase of the subject, we note Mr. Govett's tribute to Mr. W. M. Hughes, now Prime Minister of the Australian Commonwealth, who has shown a keen appreciation, so rare among British officials, of the importance of the mining industry and of the necessity for protecting the metal production of the Empire. Apparently the idea of a bounty or preferential tariff on zinc is being advocated by him as the only means of helping the Australian zinc mines against foreign competition. Already a Zinc Producers Association has been organized to facilitate the sale of the concentrate produced at Broken Hill and schemes to build smelters are being planned with the hope that the Imperial Government will grant a bounty ensuring the price of spelter being maintained at £23, or \$115 per long ton, equivalent to 5 cents per pound. There is talk of an electrolytic plant to be built in Tasmania, where cheap hydro-electric power is available. An experimental plant of this kind is being erected at Newcastle in behalf of the Zinc Corporation and the Burma Corporation, which are under the same control. Meanwhile, under the energetic leadership of Mr. W. S. Robinson, the Associated Smelters combination, which acquired the Broken Hill Proprietary's works at Port Pirie, is helping to take care of much of the lead concentrate that used to be treated in Europe. Efforts to sell zinc concentrate in the United States were checked, says Mr. Govett, by the under-selling between the various Australian mining companies, leading to a reduction in price that spoiled the business. It seems to us that the import duty and the cost of freight to this country would be enough to prevent the establishment of such a trade. To bring spelter to the United States is like carrying coal to Pennsylvania; any importation sufficient to affect the market for the domestic output would provoke the demand for a protective duty, in addition to the 10% now levied on the gross value. Evidently the future of the zinc industry at Broken Hill is not yet assured and unless artificial support is forthcoming, by tariff legislation, it is likely that hard times will ensue when War prices cease to be paid for spelter.

Another Apex Decision

On July 3 the Supreme Court of Nevada affirmed the decision of the lower court in the *Jim Butler v. West End* case. Our readers will recall that in this dispute between two mining companies at Tonopah, the trial court had decided in favor of the West End Consolidated Mining Company, as recorded in our issue of May 15, 1915, at which time we published some details of the geologic structure on which the conflict was based. We confess that the opinion of the higher court, just as much as that of the lower one, in so far as either defines and discusses the geologic features, is unconvincing. The accompanying sketch is taken from the text of the decision. Two veins meet at *B*, the north-dipping vein appears to extend upward to *A*, where it reaches the top of the trachyte, which is there covered by a later flow of

DIAGRAM OF VEIN STRUCTURE.

andesite. In short, the point *A* marks a former surface, at which the vein is cut off. The West End claimed this as an apex that gave it the right to follow not only the north-dipping vein but also the one dipping south into the Jim Butler ground. The principal feature of the case was the introduction of a theory that the two limbs of this structure constituted an antinormal arch. In the opinion of the Supreme Court the second of the two main questions of law submitted to it—the first dealing with irregularity of end lines—was “whether, within the meaning of the Act of Congress, the crest or crown of a vein which is found in the form of a single anticline may be regarded as the top or apex of the vein, and extra-lateral rights exist upon such vein in opposite directions.” The Court decides that “if it be true that the law contemplates that every vein has an apex, then it necessarily follows, we think, that the crest of the antinormal roll is the apex.” The lower court evidently was puzzled by a set of conditions so far outside the knowledge of the original framers of the law of 1872, and Judge Averill’s opinion reflected his perplexity, for he did not accept the idea of a ‘blanket’ or ‘contact’ vein, while talking about “the antinormal axis of the united main quartz bodies.” No wonder that he confessed that “the condition described is one that escaped the foresight of Congress and is also exceedingly remote from the simplicity of the plan they chose to adopt; yet the

law must be applied to it.” And the law is going to have a hard time in cracking this nut. The Supreme Court of Nevada has faced the chief problem, whether extra-lateral rights exist upon a vein in the form of a single antinormal fold and whether those rights extend over both limbs of the structure or only over the one having the same dip as the discovery vein. It decides in favor of both directions, declining to hold that “end lines may be considered as having only one direction.” Therefore there is “nothing in the statute which militates against extra-lateral rights upon such vein in opposite directions the same as though it were two veins with separate apices, instead of one vein.” A lot of space in the opinion is given to defining ‘top’ or ‘apex,’ but there is no definition of ‘antinormal fold.’ Is any continuous deposition of ore along a contact or along two contacts that intersect to be considered an antinormal if it has the shape of a fork, pent-house, or arch? Does not the term ‘antinormal fold’ suppose the bending of a continuous layer of material, not necessarily the ore that follows a bedding-plane or sympathetic fracture, but the rock in which or the rocks between which the ore lies? The existence of such a structure in the disputed ground is assumed, although the lower court was decidedly hazy on the matter, if not averse from the idea. We may add that the present writer went underground on the day when Judge Averill’s decision was published and saw the chief evidence himself in the West End mine. If his opinion have any value, it is because it is unprejudiced and is based upon an unusual familiarity with ‘saddle-reefs’ in Australia and ‘domes’ in Nova Scotia, the two types of antinormal structure pre-eminently associated with important deposits of gold ore. In the West End mine he saw nothing to remind him either of the arches of quartz at Bendigo or of the domical formation at Waverley. Of course, these orebodies follow the bedding-planes of sedimentary rocks, itself an important difference from the conditions at Tonopah. But the law is going to have other problems that “escaped the foresight of Congress.” At Bendigo there is a series of antinormal arches trending eastward, in accordance with the dip of the antinormal axis. Which is the apex, the crest of each saddle or the antinormal axis that skewers a whole series, a dozen or more, of them? Usually the rock at the highest point of the arch is cracked, and along the crack, or cracks, quartz has been precipitated, so that some sort of connection between the arches can be inferred geologically even if not proved legally. Moreover, transverse cracks, now flatly dipping quartz veins, connect the vertical series of saddles; is the one on the hanging-wall side to be considered dominant and is the apex to be awarded to it? Here’s a pretty kettle of fish for any court that tried to apply that belated anachronism the law of the apex to conditions so far beyond “the foresight of Congress.” And what of the domes? Given an orebody that followed the quaquaversal dip or domical structure of a rock formation such as that of the slate-quartzite terrain in Nova Scotia, what is the apex? A dome culminates not in a line but

in a point. Would not the extra-lateral right "flow downward" in every direction like the rain on an umbrella? We leave the problem to our readers.

Education Again

This subject is again presented to our readers in the lengthy abstract of an address delivered by Mr. Charles S. Howe, president of the Case School of Applied Science, a technical college at Cleveland that is coming into honorable prominence. We thought Dr. Howe's treatment of the question so much to the point that it deserved to be brought to the attention of the mining public through our pages. After all, few questions are more deserving of continued study than this. Education is on the operating table, as it were, and demands careful dissection at the hands of the experts, such as the chiefs of our teaching institutions. Technical education is yet in a juvenile stage, in its recent phases it is still immature, and every bit of earnest criticism helps. It has become the care of the State and of the Nation, having passed out of the dangerous patronage of private endowment. The task of the educator is a big one and terribly restricted by the element of time. Most of the elaborate schemes for giving young men a training adequate for the needs of a professional career break-down for lack of time. The necessity for earning a living, for becoming an independent self-sustaining member of the community, prevents most young men from remaining under special tutelage longer than three or four years after they have emerged from the high-school or other boyhood instruction. Many of us, long in the field, would like to return to the lecture-room and laboratory if only life were not so short. It is the old engineering problem of doing the best you can within a limited time and with limited means. And in the end we have to confess, with Dr. Howe, that "engineering education does not produce engineers." It only helps to make them. Some men are engineers by the grace of God, and education stimulates their natural faculties to the maximum of effective growth; others have no aptitude, they are innately fitted for other occupations or for doing nothing gracefully. We like the suggestion that one of the things that will circumvent old Father Time is to teach the young man where to find the information he may need in the course of his work. Not much can be given him in the way of information applicable to his daily requirements; in the short years of training he is taught to develop his faculties, rather than store his brain; and one of the most useful of those faculties is the ability to find information as occasion demands. In these days of voluminous publication, in the form of books, transactions, and periodicals, it is highly important for the young engineer to learn how to extract from the vast mass of printed matter such portions of information as can serve him best. To know everything is impossible; to know where to find the necessary information is a first aid to successful technical accomplishment. And here we confess that we wish that indexes and bibliographies were better done.

Most of them fail by being indiscriminating, giving so little hint concerning the reliability, scope, or timeliness of the information. We need an index of indexes, something to guide the seeker after trustworthy data on any given subject. No editor but is aware of the difficulty of searching for information in the jungle of non-descriptive titles and incomplete references that are his only guide, outside personal memory, in such matters. A more contentious phase of the subject is instruction by means of laboratories and extensive equipment of plant in the technical colleges. We confess to philistinism in this regard. Many schools have a lot of elaborate apparatus on a scale so large that continuous demonstration is impracticable on account of the labor required and the material consumed. We know of several mining and metallurgical plants that are white elephants for lack of ore to keep them going, not to mention the difficulty of obtaining experienced men to run them and to instruct the students intelligently in the use of them. The average exhibit of machinery in a mining school serves to advertise the manufacturers that were enterprising enough to donate specimens of their products and affords the students a measurable amount of physical exercise indoors. In after life the least practical men are apt to be those that have tinkered with such apparatus under an academic instructor. The better plan is to take the young men to the mine and mill, to put them in touch with actualities, and to teach them the purpose of it all by contact with working conditions. A wise compromise is to use not the full-scale exhibits of the manufacturer, but model plants on a scale so small that the machinery can be taken apart readily and studied conveniently. A small model will illustrate the essential principles just as well as a ponderous machine, it saves material and labor in the running of it, and it enables a variety of types to be studied without wasting the restricted space usually available for the purpose.

In the discussion that followed the address of Dr. Howe, a reference was made to the standing of the lawyer and doctor as compared with the engineer, to the disparagement of the last. Is it not a criticism on his education that he should, as a citizen, fail to have the standing of those in the allied professions? In France and Germany the title of mining engineer commands respect because it presumes a good education, not only technical but humane. That is true of the lawyer and doctor, both of whom are equipped to take part in public life. It is assumed by many that the training for the work of engineering is so insistent that no time is left for a broad cultural education, that the bread-and-butter earning must be assured and when that is done it is too late to become familiar with good literature, political philosophy, and a completeness of mental life. Nevertheless, the education of the mining engineer will be a failure unless it equips him not only to win a wage when he graduates, but to take a leading part in the community when he is twenty years older, to make him not only a successful technician but an effective citizen—a leader among men.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Surficial Indications of Copper

The Editor:

Sir—Mr. Probert has presented a valuable summary of the prominent features of secondary enrichment, covering a wide field with discriminating observation and simple statement. His papers, however, seem to accentuate the paucity of our knowledge in regard to the connection between kind and character of outcrop and kind and importance of deposit beneath it. What the engineer is seeking, and what the capitalist expects him to possess, is some body of rules which shall suffice to decipher from the superficial record the history of the changes below the surface that have made for the genesis or otherwise of mineral deposits. Outcrops vary within the widest limits in their character, even when there may be similarities in ore deposition beneath. Only in the cycle of chemical reactions operative in producing secondary enrichment is there an approach to uniformity. The number of secondarily enriched deposits in the world that has been studied has been insufficient for accurate reading of the lesson of the outcrop. A man passing from the Utah Copper to the Miami, and thence to the Ray, and the Ajo, meets with a series of unlike superficial conditions, and the world knows the story of hesitant engineers in the face of these variant phases.

This only serves to emphasize the importance of the discussion which Mr. Probert has initiated. After a mine has been proved, more attention is devoted to the underground disclosures than to a detailed study of why and how the outcrop may have indicated what lay below, but the knowledge of these relationships is precisely what the world needs as a help for finding another, and yet another, mine.

Mr. Probert calls attention anew to the favorable conditions presented by prolonged and intermittent vulcanism, and by a succession of moderately basic intrusions, followed by acid, and terminating in more basic eruptions. While generalizations are easily misleading, evidences such as these naturally induce to careful study of a region, particularly when indications of actual metallization are found in conjunction with them. Not infrequently the really valuable deposit presents fewer signs of metal at and near the surface than appear in the minor veins and zones of mineralization in the neighborhood. An investigation into the geological structure of a promising district is often the key to the discovery of an important mine.

In connection with conditions favoring ore deposition and the marks left on the surface it may not be amiss to call attention to one feature which is frequently valuable as a means of interpreting the more salient phenomena. Primary ore, preceding concentration into secondary enrichments, was not likely to present spectacular effects. Rare and striking examples of mineralization were usually absent. The outcrop examined for evidence of the relatively feeble primary mineralization may, however, disclose significant indications in portions of the rock which have not participated in those katamorphic changes that favored the leaching of the early metallic sulphides. Here the microscope is an essential aid. Even the binocular will often afford nearly conclusive evidence in the field in advance of the final revelations by laboratory study on thin sections. Mineralization of extensive copper areas has usually taken place under conditions of moderately high temperature and pressure. The metallization, moreover, has ordinarily been a product of replacement, accompanied by extensive alteration of the rock-minerals, even where the latter have not been involved in the metasomatic reactions. Important quantities of magmatic gases, occluded at high pressure in the original minerals of the rock, become liberated in this process of alteration under the influence of the later ore-depositing so-called 'mineralizers,' and these gases enter into the cycle of chemical changes. The carbonic acid gas, commonly the most abundant of the occluded gases, forms carbonates and sets silica free; while the hydrocarbons, also abundant as occluded magmatic gases in the rock-minerals of igneous rocks, perform their important function as reducing agents. The importance of the alterations throughout the mass of a rock undergoing mineralization by later invasions of heated gases or solutions as a result of the participation of the original occluded magmatic gases, is very great. A cumulative intensity of alteration results, and where a wide extent of fairly uniform high-temperature alteration is accompanied by metallization, it has generally been assisted in no small degree by the earlier occluded gases. Remnants of denser rock masses in proximity to areas of mineralization, that have resisted erosion and decay by reason of their density, may throw light on the genesis of indicated ore-bodies, and help to confirm the indications when taken in conjunction with the structural features of the region. When the remnants of primary rocks still contain occluded magmatic gases at or near the outcrop, the conditions for original (primary) mineralization, and

for the subsequent alterations which promote secondary enrichment, are relatively unfavorable.

The mining world is awaiting, with keen expectations of the solution of many a riddle, the treatise on sulphide enrichment now being prepared under the general direction of Mr. Graton. In addition to this it is to be hoped that Mr. Probert will include in the program of the University work under his charge, a continuation of his interesting study of the outcrop-criteria of orebodies, until it bear fruit in a monograph which will become a valuable practical guide for the engineer in the field.

COURTENAY DE KALB.

Tuesday, June 27.

The Discovery of Cyanidation

The Editor:

Sir—It was my good fortune to be a contemporary of Mr. MacArthur in the Tharsis company's laboratory at Glasgow from 1872 to 1879, when I left to take a position with the Sierra Buttes company in Sierra county, California. We had always been 'chummy' while working for the Tharsis company, and the friendship was continued by frequent letters after I came to California. His told me of research work he was doing on the Tharsis ore, and mine told him of the simple methods of treating the auriferous sulphides at the Sierra Buttes.

In the early days of that mine no concentration was done because it was not necessary; but as depth was attained, and the quantity of unoxidized sulphides increased, something had to be done to recover the gold in them, and in the 'seventies Hendy 'jiggers' were put in. The concentrate saved on these was spread out on platforms below the mills, mixed with salt, and allowed to weather for several months, then re-ground in amalgamating pans. This was the method I told MacArthur about and I am sure it must have seemed very primitive to him against the condensing-tower recovery practised by the Tharsis. As the proportion of ore crushed from the lower levels increased, the percentage of unoxidized sulphides increased also, and in the early summer of '84 the first shipment of concentrate was made to the Pioneer Reduction Works at Nevada City. The returns were so satisfactory that along about '85 the Sierra Buttes company put up chlorination works of its own below the Yuba mill, which was equipped with Fruevanners when it was built in 1883.

Meanwhile MacArthur was "pegging away" at his cyanide process, and in the fall of '86 he asked me to send him a small sample of Sierra Buttes concentrate. This I did, and probably it was the first product of a California mine to be cyanided.

In March '89 he wrote me that he was coming to the United States and that, after attending to his patent business at Washington, he would come to California to look over the ground and see what the prospect was for the adoption of his process in this State. It was with the greatest pleasure that I looked forward to meeting

my old chum again. As he came with gilt-edged credentials, it was no trouble at all to get the Sierra Buttes management in San Francisco to give him *carte blanche* for experiments at the mine—and so I had the honor of introducing the discoverer of the cyanide process to a gold mine.

In his tests at Sierra Buttes, and at the Plumas Eureka also, where we went later, he stuck resolutely to the custom he had established in the early days at Glasgow of "laying the gold on the table"; but, it need hardly be added, he didn't forget to assay the tailing.

In his experiments at both mines the extraction was uniformly satisfactory. There was only one noteworthy fact the significance of which none of us saw at that time. In the mill there was the usual system of boxes, below the concentrators, for saving the sulphide slime, which assayed away above the average concentrate, and the extraction was also very high. This indicated the advantage of fine grinding, but, as far as I know, none of us looked upon it as anything more than a splendid exhibition of the potency of cyanide to dissolve gold.

The Sierra Buttes management was nothing if not practical, so that, without doubting the scientific truth of MacArthur's claim for his process, they looked at him with indulgent incredulity when he spoke of its becoming a commercial success. At that time (1889) MacArthur told me he knew quite well that the cost of cyanide (it was then about 3 shillings per pound in Britain) was a serious obstacle to the general adoption of his process for the treatment of even moderately high-grade material; and the problem he had set himself then was to find some process to cheapen the cost of manufacturing it.

While in California MacArthur heard of the wonderfully rich but refractory and rebellious ore of the Meadow Lake district and he commissioned me to visit that decayed camp, as soon as the snow was off the ground, and get some samples. When I got to Cisco, I inquired about a means of getting to Meadow Lake and incidentally told the hotel people the object of my quest. They looked at me rather pityingly as if they thought I was sent on a profitless mission, but arranged for a guide and saddle-horses. Capt. Hartley received me kindly, gave me lunch, which I needed, and let me take the samples I wanted, and I returned to Cisco well pleased with my day's work. I learned the meaning of the pitying smile of the morning when the proprietor told me that Capt. Hartley's usual reception of any unaccredited visitor who went to him for samples and information about his property was to drive him off the premises at the point of a shot-gun. The samples were taken at random from shallow pits and open-cuts along the croppings without any attempt at system, the purpose being simply to find out if this rebellious ore would yield to cyanide solution. Some of the samples were fairly rich, others quite poor, but they all yielded readily to cyaniding. Nothing came of the Meadow Lake business for the reason that Hartley wasn't buying processes and the Cassel company wasn't buying mines.

In the fall of '89 I was at Crestone in Colorado when the advance guard of the Cassel company pitched its first camp in the United States. At Crestone I met P. George Gow, who four years later was in charge of the Cassel company's exhibit at the Midwinter Fair in San Francisco. In the summer of '93 he came to Grass Valley and took samples of North Star tailing for a working test at the Cassel company's experimental plant at the Fair. His report was that the North Star tailing was too low-grade to cyanide at a profit. Now the North Star company is cyaniding thousands of tons profitably every month. As MacArthur states in his article, there has been no radical change of, or addition to, the process since '88, but improved mechanical methods have made the difference between profit and loss.

Grass Valley, June 29.

An Earthquake in Nevada

The Editor:

Sir—I have read the account of the earthquake at Kennedy by S. L. Berry. It is also true that we still have quakes and rumbles every day. At Winter's ranch, six miles below here where there are hot springs, there are 15 and 20 shakes a day right along since October 15 last. Lately we have had quite a few rumbles and jerks, but not heavy enough to do damage; Kennedy is 30 miles south of here. The earth is cracked all along the foot of this range on the north-west side of the Stone House valley, two miles below here. It is also true that water is running in creeks and gulches where the old-timers have never seen it run before.

LORING HANSON.

Golconda, Nevada, July 12.

Prospecting: A Suggestion

The Editor:

Sir—"What's Wrong with Prospecting?" has become a familiar caption in the mining press. We have read the lamentations of those who mourn the passing of the old-time prospector until many mining men have come to feel that much of this vain yearning for 'the good old days' bespeaks negative suggestion. Yet the recent renaissance of mining has encouraged prospectors to resume their ancient and honorable calling. Exploration companies and syndicates had been setting the pace because they alone knew the value of expert prospectors in their organization. Metallurgists, chemists, assayers, and other surface men, knowing the actual commercial values of ore deposits, have blossomed forth as 'prospectors' of the new school. The use of the mining engineer for directing explorations for small operators has not been emphasized.

Let us consider a hypothetical mineral district worthy of exploration, such as the partly prospected and developed mineral district in the Siskiyou mountains, California. This region has been skimmed over by pros-

pectors for gold, copper, and lead during the past fifty years, but their work was desultory in character. With the extension of motor-truck transportation, considerable activity is being aroused. Prospectors are renewing their efforts as individuals, but their explorations would be far more effective if co-ordinated. This is the field in which the exploration syndicate could operate with good prospects of success.

Here is how the old and new methods of prospecting will compare. Probably a score of prospectors within a year will visit a particular portion of the Siskiyou mountains, an area 20 miles from east to west and 14 miles from north to south. Several of them will undoubtedly follow outcrops and locate a number of claims. Suppose that four or five men out of twenty locate claims that give promise of becoming paying mines. Of these, only one individual prospector succeeds in getting enough backing to develop his property. This 1-in-20 chance is a fair proportion. The other 19 spend from \$5000 to \$10,000 to no purpose. Even the one lucky one has made a random hit. He may have passed over dozens of richer deposits in his hurried wanderings. Most of the unlucky 19 are backed by investors who have 'taken a chance.' Some of these losers are not good losers and they seek solace in calling mining a 'losing game.'

Co-operative prospecting, on the other hand, might be conducted in a radically different manner. Let us assume that this particular district is worthy of systematic exploration for a summer. What would it cost? Suppose that a group of 20 investors subscribe a total of \$5000 to an exploration company and plan to devote that sum to a thorough reconnaissance of the district. They make a wise start by employing a mining engineer who is qualified to conduct a geological survey and to direct the efforts of prospecting parties in the more promising sections. He spends the month of June in traversing the ridges and canyons of the region with a skilled assistant and a handy man who combines the services of a packer and camp-cook. At the end of June he defines three zones, X, Y, and Z, as areas in which he proposes to confine the efforts of three experienced prospectors. Each prospector has a man to help him, and, besides a fair salary, has the additional incentive of a bonus of from \$500 to \$1000 offered him for the making of a 'strike.' A regular cook is then employed at a base camp, while a packer travels from camp to camp carrying provisions and supplies to each station as well as from the railway or stage shipping point. The engineer's assistant helps in the field-work, in mapping, and in making assays at the base camp.

By the end of July, prospecting in zones X and Z does not show results, but the prospector in zone Y discovers a series of outcrops trending in a north-westerly direction from the middle fork of Creek B across the divide to the east fork of Creek D, a distance of six miles. A distinct silicification is traced along the line of a fault traversing this favorable formation. The four men covering zones X and Z are called in and set to work exploring the vein system discovered in zone Y. Let us

assume that the original strike was made at the middle fork of Creek B. Subsequently, the prospector from zone Z discovers an extension a mile below the head of the North Fork and the largest and richest orebody is proved to exist there. Exploration work is then concentrated there during August with the result that the driving of several hundred feet of tunnels and the sinking of shafts with cross-cuts demonstrate the existence of 150,000 tons of ore having an average value of \$8 per ton. Prospectors Y and Z share ultimately in a bonus of \$1000 paid them in the same way that salesmen working on a salary and commission basis earn their bonuses for sales made. Prospector X is not so fortunate, but he may benefit by working into a steady job when the mine is developed. A number of claims are staked in zone Y and the exploration company has something to show by the end of August. Here is the cost sheet of this theoretical reconnaissance:

LABOR AND SUPERINTENDENCE

	June	July	Aug.	Totals
Engineer in charge.....	\$250	\$250	\$250	\$750
Assistant to engineer.....	100	100	100	300
Cook and packer.....	75	75
Regular cook	50	50	100
Regular packer	60	60	120
3 prospector-miners at \$90.....	...	270	270	540
3 muckers at \$70.....	...	210	210	420
	\$425	\$940	\$940	\$2305

OTHER EXPENDITURES

Provisions	\$ 50	\$150	\$150	\$350
Camp equipment.....	150	125	25	300
Mining tools	25	75	50	150
Powder, caps, fuse.....	20	80	200	300
Assays and assay equipment....	50	300	50	400
Transportation	150	100	100	350
Miscellaneous expenses	50	75	75	200
	\$495	\$905	\$650	\$2050
Grand total	\$920	\$1845	\$1590	\$4355
Balance in treasury.....				\$645

Assuming that a bonus of \$1000 is due prospectors Y and Z, the total cost of such systematized prospecting would, according to these convenient figures, amount to \$5355, to say nothing of a tidy little bundle of stock certificates in the re-financed company which the engineer ought to have coming to him.

Of course this theoretical prospecting trip had to result in the discovery and blocking out of an orebody that showed up 150,000 tons of \$8 ore. Furthermore this ore must be supposed to yield a net profit of \$3 per ton after an additional investment in surface equipment and working capital is made. This figures out very nicely as a business proposition in which the original investors and their financial allies subscribe just \$105,355. Even if they do not open up new orebodies and confine their operations to the proved deposit, there is the difference between \$150,000 gross profit on ore extracted and the total investment of \$105,355, a net return of \$344,645 on such enterprise. If it takes seven years to exhaust

this orebody, there would be a net profit of 327%, or 46% per annum, on the investment. Now, if the original 20 men who raised \$5000 for such systematic prospecting were to sell their mining land for what it would be reasonably worth, \$75,000, they would clean up 1500% on their speculation. As a business enterprise this beats 'hogs and alfalfa' or 'bees and wild honey.'

Mr. Doubting Thomas, taking a contrary view, may say: "Suppose the original reconnaissance party of three, after a June outing in these delectable mountains doesn't find any 'zones' like X, Y, and Z worth further exploration." They will be out of pocket, but only to the extent of \$920. Divided between 20, the average loss would be \$46. If these twenty had separately 'grub-staked' 20 different prospectors for the same amount, approximately \$5000 in all, their loss would have been \$250 per capita and their chance of sharing in the half-interest proposition of the old-time prospector relatively less.

HAROLD FRENCH.

Oakland, June 30.

ROCK-DRILL practice on the Rand usually works out differently than in the United States. In the Transvaal, the miners are Kafirs drilling exceptionally hard rock in flat narrow stopes. New devices are apt to be looked at askance, as these miners do not take readily to complicated mechanisms. Recently the electric firing of blasts was tried on a thorough scale at the Meyer and Charlton mine where conditions were believed to be favorable. The experiment was unsuccessful, and the electrical equipment was removed. The blasting of so many holes simultaneously injured the hanging wall and misfires were common. The *South African Mining Journal* reports that "interest has been aroused among engineers and mining men on the Rand regarding the application to rock-drills of the newly discovered method of transmitting power known as wave transmission." As yet this new method of applying power to drilling rock is said to be in the experimental stage, and details have not been made available.

THE CALUMET & HECLA company, which recently celebrated the 50th anniversary of mining on its lands, awarded gold, silver, and bronze medals to its oldest employees. Over 160 men have worked for the company from 40 to 50 years, and one man, Timothy O'Shea, has worked 50 years and six months. Several hundred have worked 30 to 40 years and nearly a thousand have worked 20 to 30 years. In an age when labor is restive, these figures are particularly noteworthy. Among the old employees are such Cornish names as Edyvean, Johns, Jory, Trevorrow, Thomas, Tonkin, Cuddihy, James, Nancarrow, Richards, Soddy, Trathen, Bennetts, Williams, and Penhall. Other nationalities among the veterans include Kelly, Doyle, Dooley, Carlson, Govette, Koch, Kjolso, Kruska, McLean, MacNaughton, Venturino, Swanson, Pyrrhus, Abramson, Jolicœur, Marchetti, Salotti, Baranowski, and Campbell.

The Bolivian Tin Industry

By Howland Bancroft

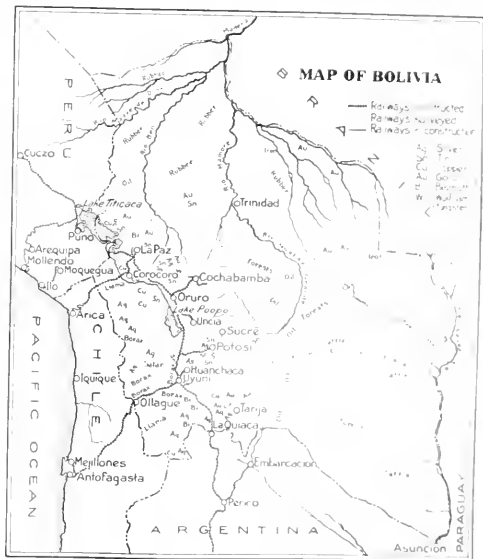

INTRODUCTION. *Interest in Bolivia as a source of future supply of tin for the increasing demands of the United States began to appear when production from Bolivia exceeded for the first time the combined production of Banka and Billiton. Prior to 1905 the production of these Dutch colonies was second only to that of the Malay Straits. In 1905 the Bolivian production passed 16,000 metric tons of metallic tin¹ while the production from Banka and Billiton fell from the record figure of 20,000 metric tons in 1903 to 12,000 metric tons in 1905, since which time their combined production has not equaled the Bolivian output. In 1897 the Bolivian production first commenced to be an important factor, and this output has persistently increased.

Since my first trip to South America, I have seen many improvements accomplished in the railroad system of Bolivia, while outside the Republic marked progress has been made in the treatment of the ores by those interested in obtaining a clean product, in order that Bolivian ores might command as high a price in the market and be as suitable for use in the tin-plate industry as those from other, and, I might say in this respect at least, more favorably known localities.

The declaration of war in Europe caused some speculation in the United States in regard to the supply of tin for domestic consumption. As Great Britain controls a majority of the world's production, a possible embargo on the exportation of this metal was anticipated with a foreboding that proved correct. When the embargo was put into force by Great Britain, it became evident that Bolivian tin ores could not be safely shipped to Germany for reduction, and, to cap the climax, British smelters raised their charge fully 80%. In consequence, a great hue and cry was raised in Bolivia as to who would smelt their tin ores. Much discussion followed and a great many communications were exchanged regarding the erection of a tin smelter in the United States. Several groups talked about undertaking this, but to date, only one company has done anything toward actually building a smelter.² In 1915, the American

Smelting & Refining Co. began constructing a tin smelter at Perth Amboy, New Jersey; it went into operation in March 1916. This plant has a capacity of 8000 to 10000 tons of metallic tin per year, or a little less than two-fifths of Bolivia's present total output, the remainder of which will doubtless be smelted in British furnaces until the end of the European war, after which American, English, or German tin contracts with Bolivian producers will depend largely on the prices offered.

WORLD'S PRODUCTION OF TIN.³ Reference to Fig. 1⁴ will show the production of tin from different countries of the world. It will be seen that the Malay States, or,

as they are also known, the Straits Settlements, produce somewhat more than half of the total, while the combined production of tin in British possessions and protectorates amounts to about 60% of the world's production. Next in importance is the Bolivian output, which in

requesting special concessions for treating the Bolivian output in electric furnaces to be erected in the Republic. However, as yet no announcement has been made of the erection of a plant to smelt tin ores electrically.

All generalizations regarding productions, values, and prices refer to normal, not war, conditions.

Frank L. Hess of the U. S. Geological Survey kindly consented to bring the figures 1 and 2 up to date from 1912, as I was not in the United States until a few days before the presentation of the paper, and such statistical information was not conveniently at hand in the field.

*A paper read before the second Pan-American Scientific Congress at Washington, and revised subsequently by the author.

¹Throughout this paper references to productions of tin are to metallic tin, not to the concentrate or 'barilla' from which the tin is obtained.

²It is to be remarked that four United States companies offer to treat Bolivian tin ores, two of which contemplate smelting these ores in electric furnaces. Furthermore, a French commission has studied the available hydro-electric power possibilities in Bolivia with a view to erecting smelters there. Also, a considerable amount of agitation is apparent in the Bolivian capital regarding bills introduced to Congress

1913, passed 25,000 metric tons, or about 20% of the world's total. Banka is the only other country having a production that exceeds 5% of the world's total, and in 1912 Banka was credited with a yield of about 16,000 metric tons, or 13½% of the total. Cornwall, Australia, China, South Africa, and Billiton make up the remaining 17% of the world's output, and, as above stated, the individual productions of each of these countries is less than 5% of the tin production of the world.

On the same diagram will be seen a curve representing the total amount of tin produced in countries other than British possessions and protectorates, a curve showing the consumption of tin in the United States, and also a curve illustrating the value, in millions of dollars, of the world's production of tin between the years 1897 and 1915.⁵ Some notable facts are illustrated by these diagrams. For example, the total amount of tin produced in countries other than British is less than the amount consumed in the United States, and has been less during the period covered by this diagram. Further, in the last few years the value of the world's production in millions of dollars has been about equal to the world's production in thousands of metric tons. In other words, during that period the value of a thousand metric tons of tin has been, in round numbers, one million dollars. In this connection Fig. 2 will be of interest; on this diagram is shown graphically the average monthly price of tin at New York during the period covered by Fig. 1, namely, between 1897 and 1915. It will be observed that the price, with some exceptions, has risen steadily from 13 cents per pound in 1897 to over 50 cents per pound in 1912 and 1913, since which time it has fluctuated between 50 cents and 30 cents.⁶ Between 1897 and 1915 the world's production has increased from 75,000 metric tons to over 120,000 metric tons of tin. This continued increase in production, accompanied by a more or less constantly advancing price, is worthy of especial remark.

UNITED STATES CONSUMPTION. Since 1897, or, in the last 19 years, the importation of tin into the United States has increased from 25,000 metric tons to over 50,000 metric tons, having passed this figure in 1912. The growth of domestic consumption has been due largely to the steady growth of the American tin-plate industry, although the large use of tin tetra-chloride in the silk industry has had a considerable effect on the amount of metal consumed. During the same period the British tin-plate industry has decreased proportionately, the protective tariff in the United States being not only responsible for the rapid growth of our own tin-plate industry, but also for the decline in that industry in Great Britain, from which country the United States purchases 90% of the pig-tin it consumes. The United States Steel Corporation is the largest individual con-

sumer of tin in the world, the American tin-plate industry having been developed by this corporation. It is to be remembered that the available supply of tin from nations other than British possessions and protectorates is less than the amount consumed annually by the United States.

Here follows a brief statement regarding secondary tin in the United States. This industry has grown from a small beginning in 1900 to such proportions that the secondary tin recovered in 1913 equaled 14,178 tons, valued at \$12,567,379, and the recovery for the year 1914 was 12,447 tons, having a value of about \$8,887,158. These figures represent respectively 27.2% and 26.2% of the importations of tin into the United States and indicate a constantly increasing domestic source of tin supply. J. P. Dunlop states:⁷ "The recovered tin includes the tin content of products made by several plants from tin scrap. These include some tin oxide, putty powders, etc., but consist mainly of tin chloride, stannic and stannous salts. Stannic chloride is usually sold either as a water solution, called bi-chloride of tin, or as an anhydrous sirupy liquid, termed tetra-chloride of tin, and is used principally in the silk industry. Stannous chloride is sold in the form of crystals and is used in dyeing and calico printing. Most of the tin oxide, tetra-chloride, and other products were made from clean tin-plate clippings, or from tin liquors left in dyeing and weighting silks. The dry chlorine process was used to recover the tin from the clippings in some places; in others reverberatory furnaces were used to remove the tin coating, and a large quantity of tin was recovered in the form of a tin powder by the electrolytic treatment of clean scrap, the powder being sent to secondary smelters. The largest recoveries of tin were made from the scruff and drosses that occur in making tin and terne plate, and amounted to over 5000 tons. The recovery of tin from block tin pipe, tin foil, and old tin cans was relatively small. Only one firm reported using old tin containers, from which the tin and solder were first sweated and the black plate re-melted to make sash-weights. The principal alloys in which secondary tin was recovered were babbitt and other bearing metals, bronze, solder, pewter, and electrotype metal."

BOLIVIAN PRODUCTION. The production of tin from Bolivia in 1863 was only 493 tons,⁸ while the following year the output was only 204 tons, and it was not until 1888 that the annual production exceeded 1000 tons.⁹ The production from this date until 1898 fluctuated under 3000 tons per annum. Since 1898 the production has been almost continuously increasing until in 1913 it passed 25,000 metric tons. See Fig. 1. While a glance at this diagram would lead one to believe that the Bo-

⁵This period is chosen for the reason that prior to 1897 the Bolivian production was too small to be considered as important among the productions of other nations.

⁶During August, 1911, tin was quoted at 65c. per pound in New York. However, this price was maintained only for a brief period.

⁷Mineral Resources of the United States, U. S. G. S., 1912.

⁸All figures regarding production of tin refer to the amount of metallic tin contained in the ores produced and shipped, and do not refer to 'barilla,' in which form it is customary to refer to the production of tin in Bolivia.

⁹Mineral Industry, Vol. I, p. 450 (1892).

livian production represented normal growth, it is necessary to know certain pertinent facts regarding the actual production from the individual mines before coming to any conclusions regarding the stability of the Bolivian tin industry as a whole. For example, one mine produces roughly one-fourth of all Bolivia's output. A contiguous property could easily produce another fourth, but the policy of the management seems to be rather to keep to a nominal production of 12,000 quintals per month, this representing 17.3% of the total output from Bolivia. Of the remaining 58.7%, three-fifths comes from Huanuni, Compania Minera de Oruro, Araca, Aramayo Frank & Co., Soux, Bebin Brothers, and the Avicaya properties. A large proportion of the output therefore comes from a comparatively few mines, over two-fifths from two contiguous mines in one district. Consequently, the increased production from Bolivia is traceable to the efforts of two companies, and if they stopped operating the total output from Bolivia would drop to a third-rate place among tin-producing countries. The relatively small proportion of tin produced by the intermittent shippers, representing a little over 20% of the total production, comes from numerous properties, more than 25 others, which are not continuously operated, and which ship from a few hundred to a few thousand pounds of concentrate per year.

The reason that relatively few Bolivian mines produce tin in quantity seems rather to be due to a general lack of foresight and enterprise on the part of the owners than to a poverty of ore. Owners of prospects not blessed with much in the way of worldly possessions are usually not only too poor to develop but are likewise unable to pay taxes. In consequence, these so-called owners keep on denouncing the deposits over and over again, either each succeeding year, or often enough to complicate the titles. Further, any deposit so rich that it can be worked with profit from the surface is gutted without regard for the future. The natural and obvious result is that when the rich ore-shoot is mined, or when the grade falls off to such an extent that profitable mining is no longer possible with the crude and wasteful methods in vogue, there is no ore developed, no money for development, and no money available for the purchaser of equipment. The same generalizations hold, with possibly two exceptions, even among the few mines that are contributing four-fifths of Bolivia's total production. In consequence, we have here to deal with a few productive properties, none of which have any reserves assuring a continuance of output for any considerable period.¹⁰ In short, the Bolivian production has

gained its present importance through the development of a very few mines, which have practically paid from the grass-roots. Other properties are mere prospects and have no assured future. However, to one who has studied practically all of the properties of commercial importance, and has at the same time examined the region carefully, it is quite apparent that the Bolivian tin industry is still in its infancy. However, I believe that this industry, if aided by the Bolivian government in the enactment of just mining laws, regulations, and taxes, so that the foreigner¹¹ will not want to keep out, is destined to expand to first importance.

Just now the Bolivian government, in common with other South American republics, is financially hard-pressed, and, as a consequence, in attempting to mitigate

FIG. 2. THE PRICE OF TIN AT NEW YORK.

its troubles, it turns instinctively to the mining industry, which is really its backbone, although usually unappreciated. To raise money, Congress considered a law compelling all of the tin producers to buy 20% of their foreign exchange drafts (in payment for barilla exported through the National bank at the standard par value of the *boliviano*, which is fixed by Congress at 12.50 bolivianos for one pound sterling. This is all very well when the exchange on bolivianos is at par. However, when the law was being discussed, exchange was anything but normal, and this order, if passed by Congress, would have amounted to an added export tax of \$1,498,510 U. S. currency, which would be an appreciable addition to the export tax. To make this more clear: Under normal conditions the English pound sterling is worth \$4.8665 U. S. currency, and has a value in bolivianos fixed by the Bolivian government of 12.50 bolivianos. This makes a boliviano worth 38.93 cents U. S. Taking, for illustration, the present value of the boliviano as being 30.3c, the difference in its purchasing value and the value at which mine-owners, according to this law, might be compelled to buy one-fifth of all their drafts amounts to 8.63c U. S. for each boliviano involved in the transaction. Now, the tin industry re-

¹⁰While the production of tin from Bolivian placer deposits is small at present, there exist placer deposits that have been practically unexplored, although one large American company has done some drilling with unsatisfactory results, so I am informed.

¹¹Considerably less than 50% of Bolivia's tin production comes from Bolivian-owned mines, and of this portion only a small amount is produced from mines owned by a capable energetic Bolivian gentleman who lives in Europe; the rest of the Bolivian output is produced by mines controlled by men of foreign birth.

Bolivia has an annual gross value of roughly \$25,000,000. One-fifth of this is \$5,000,000. At the value of the boliviano as fixed by Bolivian law, \$5,000,000 U. S. equals 12,843,565 bolivianos. At the present value of the boliviano the same amount of money equals 16,501,650 bolivianos, a difference of 3,658,085 bolivianos or \$1,108,510 at present exchange. This would go through the Banco de la Nacion. The purchase of 20% of the drafts at the rate of exchange fixed by the Bolivian government would bring in an annual revenue of \$1,108,510. Now, as the production of tin in Bolivia is at present roughly 50,000,000 lb. per annum, and this added exchange amounts to 110,851,000 cents, it is equivalent to adding an export tax of 2.21c. on each pound of tin contained in the barilla exported, which, added to the already existing export tax on tin (which ranges from 0.86c. per pound to 2.08c. per pound, according to the London quotation on Straits tin) would make a total export tax ranging from 2.77c. to 4.36c. U. S., figures that are appreciable, to say the least, and that would undoubtedly have the effect of hindering, if not stopping, the exploitation of some Bolivian tin mines, for the simple reason that 4 cents gold per pound of tin produced is perhaps the limit of profit in many of the operations.

It is to be remarked that fortunately this legislation failed to become effective. However, the very fact that such a measure was proposed indicates an attitude on the part of the Bolivian government that is anything but conducive to the introduction of new foreign capital, and that appears rather hostile toward the investors already in the field.

OWNERSHIP OF TIN MINES. There are in Bolivia at present 9 or 10 mining companies producing tin concentrate in quantity. Of these, two groups produce 48.8% of the total production. It will be interesting to note the nationality of the control in these companies. Two are Bolivian, two Chilean, two French, two English, and one Italian. The two companies that are distinctly Bolivian produce in the neighborhood of 15,750,000 lb. of tin per annum. The two Chilean companies contribute about 12,300,000 lb. The two English and one Italian¹² mines produce about 7,150,000 lb., while the production of the two French companies is roughly 3,600,000 lb. The total is 38,800,000 lb., or roughly four-fifths of the total Bolivian production.

In considering the importance of this ownership to possible relations with smelters in the United States, it will be interesting to know that one American smelting company has contracted for the total output of the two Chilean companies for a period of one year, and has also contracted for the output of one of the companies classed as English. This represents contracts for about 7000 tons of metallic tin per year, or 28.2% of the Bolivian production.

Prior to the War the price charged in England for

smelting Bolivian tin ores of a rather impure character ranged from about \$58 to \$72 per ton of material treated, which price was advanced from \$121 to \$145 when hostilities commenced. The American company offered a certain concern a two-year contract at \$97.20 per ton of material treated, but the offer was not accepted. Before the War a German house smelted tin ores for a Bolivian-owned mine for \$34.02 per ton and for a French-owned property for \$43.74 per ton, the difference in smelting charges being due to the impurity of the ores from one of the mines and to the difference in the amount of material treated for the two companies.

As long as the European war lasts the matter of getting Bolivian tin ores for American smelters should (barring adverse Bolivian legislation) be an easy one, and at present only 28.2% of the total output is under contract to Americans. By reason of the high smelting rate existing in England and the practical impossibility of getting tin ores into Germany for reduction, it seems reasonable to suppose that the Americans will have no difficulty in obtaining as much of the Bolivian tin product as they desire. On the conclusion of the War, however, the matter will be more serious, the American tin smelters will have to be prepared to stand strong competition, for the price of \$34.02 per ton formerly granted by the Germans does not represent the lowest possible price at which the same house could smelt these ores at a profit, and when again entering the market, they will undoubtedly be willing to accept a smaller profit in order to regain the business they will have lost through the erection of one tin smelter in the United States and the completion of others now planned.

It is my belief that the nationality of the owners of the mines will have nothing to do with the placing of their smelting contracts, except in the event of equal prices being offered, in which case presumably the contract would go to a house of the same nationality. However, granting this, the English, so mixed up in tin smelting, and the Germans, though not so heavily interested, control but a small proportion of the Bolivian output through mine-ownership, while Italian, Bolivian, Chilean, and French custom smelters do not exist. Hence the conclusion seems justified that Bolivian tin contracts will go to the highest bidder, regardless of nationality.

MINING AND MILLING METHODS. In general, Bolivian tin-mining methods are crude in the extreme. This statement applies with equal force to all but a very few of the mines at present important. All of the properties in Bolivia have been gophered in their upper and richer portions, and but few of the companies are at present attempting to mine along improved methods. Furthermore, in many instances, instead of following a vein on a comparatively flat dip, circuitous inclines are sunk entirely off the vein. Naturally, the lode is not exposed, and if ore is again encountered, it is impossible to say with any degree of certainty whether it is the same orebody worked above or not. This makes little difference to the owner, as he will mine any ore so long

¹²The production of the English and Italian companies is given as a total to avoid disclosing actual individual productions.

as it is profitable. However, to an examining engineer such methods are confusing and unsatisfactory to the last degree. This hand-to-mouth method of mining leaves little in sight for the future, and is a serious hindrance to further exploitation of the mine after the richer portions have been mined out. The properties will then remain idle until someone with a little more energy and money takes hold, and by dint of more gophering manages either to lose his money or perhaps luckily uncovers another ore-shoot, in which event everything goes along as before until the ore-shoot is worked out. No money seems to be saved for just such contingencies, and with the almost complete lack of development the pinching out of an orebody may mean disaster to the company. At this point the owners are willing to sell, and seem to fail to understand just why American engineers do not evince more interest in their deposits, the skeleton of which is shown with the verbal record of past production! Furthermore, the owner seems disinclined to listen to any kind of purchase price other than one at least equal to what he imagines the mine has produced in the past, although nine times out of ten, he will be unable to show any authentic record of what this production has actually been.

Lack of surveys, unfamiliarity with the type of deposit being mined, and the absence of a scientific study of the nature of the veins or the possible extent to which such veins will be productive may be responsible in some measure for the peculiar mining methods in vogue. More probably they are the direct result of the methods introduced by the Spaniards some three centuries ago. Indeed, this brief description of Bolivian mining methods would be incomplete if I failed to draw attention to the unique mining methods that prevail at the Cerro de Potosí, a mountain that has probably given more mineral wealth to the world than any other. Here the old Spanish *boca mina* law is still followed literally, though not in the spirit of the law. Our own apex law is bad enough, but the *boca mina* (mine-opening) law caps the climax for absurdity. For example, the right to a mine-opening is granted by the State. Then the miner may go wherever he pleases underground, so long as he does not cross a previous underground passage. The result naturally is that the underground development more closely resembles a jig-saw puzzle than a mine, for, on breaking into a previously existing opening, the second operator simply goes around this in the event it is a shaft or winze, or, if it happens to be a level, he goes over or under it and continues. This leads to anything but peaceful mining conditions. Riots have been common, and pitched battles have taken place underground. Resort to arms is not confined to the Potosí district, however, for nearly every important mine in Bolivia has had some sort of an armed fight with its neighbors, and rifle racks are still to be seen in the administration buildings at some of the prospects.

The question of the amount of erosion that has taken place since the veins were formed is one, I venture to say, the importance of which has not even impressed

itself upon the minds of the operators, and so quite naturally, no attempt has been made by the Bolivian operators to gather sufficient data upon this very important subject. Since little money is expended purely for development, this lack of appreciation of the value of knowledge concerning the possible depth to which the veins can be expected to be productive has caused no great waste of money. However, long adits have been attempted, in fact, are at the moment being driven, and a careful study of the genesis and mode of deposition of

FIG. 1. THE PRODUCTION OF TIN BY COUNTRIES

the tin ores in each particular case would have determined the logical place for these adits, and would have made some rather expensive holes of much more practical value.

Although several so-called up-to-date mills are in operation in Bolivia, the loss in the tailing is remarkable, the cause for this being disputed among the managers. Some lay it entirely at the door of the native millmen, who, they justly claim, will at times allow the concen-

trate from the tables to run for hours into the tailing-box, with the natural result that the saving is low, and the tailing contains appreciable quantities of tin. I am inclined to believe, however, that these losses are largely the result of a misunderstanding of the possibilities (limits) of the machinery installed, in other words, a lack of expert administration, for few of the mills have men in charge that have gained their experience elsewhere. I talked with several managers who had never visited other properties in the same district, and few of them are conversant with the mines and mining conditions existing elsewhere in Bolivia. This does not tend toward efficiency, and the owners are more to be criticized in this connection than the managers, to whom too much work is frequently detailed to allow of their going about to see what class of ore others are treating and how successfully they are accomplishing their purpose. It all harks back to the gophering hand-to-mouth method of mining, the axiom being: "Spend as little as possible in any direction, and get as many quintals of barilla with as few laborers as you can and with as little foresight as is convenient." This seems like a severe criticism, but I speak advisedly. While Bolivians are good miners in that they produce good ore and concentrate at a small initial expense, they do so with a tremendous loss of resources and no conception of efficiency in its broader sense.

SMELTING IN BOLIVIA. Until quite recently tin ores were smelted in water-jacket furnaces at Potosi, the impure product being shipped to Europe. It commanded a lower price than Bolivian tin made from barilla shipped direct to Europe, and smelted there, and, as a consequence, a short time ago the Potosi shipper was notified that the European buyer preferred to receive only barilla, since which notification no bar is believed to have been shipped from Bolivia. (The completion of the Potosi branch of the Antofagasta-Bolivia railroad has allowed of the cheaper and more expeditious handling of freight, and so the former absolute necessity of reducing the bulk as much as possible on all freight shipments from Potosi is not now so urgent.)

Sometime before the War, a French commission arrived in Bolivia to study the available hydro-electric power possibilities of that country with a view to erecting electric tin smelters. The Government looked upon the project with a considerable amount of favor, and undoubtedly gave the commission certain unofficial encouragement. Following the War, however, the French commission, realizing the impossibility of carrying out the project during European hostilities, released the Bolivian government from any obligation. Subsequently two bills were introduced to the Bolivian Congress by representatives of two different United States companies, both of the bills having for their object the establishment of tin smelters to smelt tin electrically. These bills were too general in their demands, and too sweeping in their nature, to allow of favorable consideration. Because of the desire on the part of the promoters of the projects to establish a limited monopoly on the Bolivian tin output,

other requests have been made with a view to keeping the barilla within the country until after it has been smelted in the proposed electric furnaces, none of the plans for the erection of which seem to have been at all thoroughly elaborated. I believe that any sort of a monopoly on the smelting of Bolivian tin concentrates will only ensue from the actual erection of furnaces of sufficient size to treat the total output, and this will have to be obtained by the offer of competitive rates to the ore-producers, in other words, ordinary business practice. I am inclined to believe that the Bolivian government would look with considerable favor upon the erection of tin smelters within its borders, and if they proved beneficial to the industry as a whole, that is, in other words, to the Bolivian government, there is little doubt but that they would receive full protection from Congress.

PRODUCTIVE AREA. Argentine, Chile, and Peru have many geological relationships in common with those of the tin-producing districts of Bolivia. Notwithstanding this, Bolivia is the only South American country from which there is an appreciable production of tin ore, although cassiterite has been found in the mountainous districts in all of the contiguous republics, and it is to be expected that mines will be developed in these countries in the future.¹³ While tin ores are found over an area that covers 100,000 square miles of the Bolivian mineral belt, the principal properties are in the departments of Potosi, Oruro, and La Paz. Between the main ranges of the Andes broad flat pampas extend for many miles, the mean elevation of these being 12,000 ft. above sea-level. Some of the peaks in the ranges that bound these pampas rise to elevations of over 20,000 ft.; the average, however, being considerably nearer 15,000 ft. Tin ores are found in localities scattered throughout these mountains. In general, the deposits now being exploited occur between the elevations of 12,000 and 16,000 ft.; although in one locality such deposits have been exploited at an elevation of 19,000 feet.

CLIMATE. In general, the climatic conditions and high elevations do not tend to facilitate mining: the efficiency of human labor is reduced, a minimum of work is accomplished by beasts of burden, and the rated horse-power of all gas and other engines is decreased by from 3 to 4½% for every 1000 ft. rise above sea-level. Wind electrical storms of great intensity are frequent, and the rare atmosphere of the higher altitudes detracts from the efficiency of human effort. Several types of climate exist in Bolivia, depending largely upon altitude, though influenced to some extent by latitude. As nearly all of the tin properties in Bolivia are in the higher regions, we are concerned principally with the conditions existing between the altitudes of 11,000 and 16,000 ft. above sea-level. Two seasons are conspicuous, the rainy season, which lasts from November until March, and the

¹³Witness the tremendous expansion of the tungsten industry in Peru during the last six years, an industry dependent upon a metal the deposition of which is closely allied to that of tin. Argentine also has a tungsten industry.

dry season, from April to October. These two seasons are not marked by any considerable change in temperature and rains also occur throughout the so-called dry season. In the regions above 15,000 ft. no rain falls, the precipitation being in the form of hail or snow. It is quite possible to spend weeks at a time in the higher regions of Bolivia during the rainy season without once getting a glimpse of the sun. And it is to be remembered that all of the tin-mining districts of Bolivia are within the tropics, where the days are frequently uncomfortably warm and the nights dangerously cold.

VEGETATION. The tin-producing districts of Bolivia are barren of indigenous trees. Eucalyptus trees have been tried at altitudes up to 12,000 ft., and because of their rapid growth would prove of tremendous benefit within a comparatively few years if planted in large numbers. *Turba*, a sort of peat, serves as fuel, for which purpose a resinous plant called *yareta* is also used. However, the accumulations of *turba* are limited, and the growth of *yareta* is slow, while the consumption of both for use as fuel is high. Hence the supply is being rapidly depleted.

WATER. Properties situated near the snow-line are peculiarly favored in one respect at least, they have an abundant supply of water. In general, water is scarce in the tin-mining districts of Bolivia. However, there are running streams, and while these are not always conveniently situated, they afford, nevertheless, ample water for concentration works as well as for hydro-electric purposes.

TRANSPORTATION. The departments of La Paz, Oruro, Potosi, and Cochabamba are traversed by railroads over which combined cargo and passenger trains are run at sufficiently frequent intervals to take care of the business offered. However, if you miss a train you may have to wait a week to go 160 miles. Naturally, the completion of each projected branch facilitates shipments, and reduces to some extent the former freight rates. The railroads are notoriously high in their charges and there is still much to be desired in the way of reasonable freight tariffs. While the cart-roads in Bolivia are numerous, there are many properties to which no kind of road has been constructed. A few of the mines are well situated as regards railroad transportation, but the majority of the deposits are at a distance from railroad points, and the tin ore in the form of barilla is transported from these localities by carts, mules, or llamas. The bulk of the tin concentrate is carried at least 10 to 15 miles to reach a railroad station. Two-wheeled carts drawn by from 6 to 12 mules will transport from 2 to 3 tons, a mule will pack 200 to 300 lb., and llamas carry about 75 lb. each. The wet season interferes with transportation by carts as well as by mule-back, and during very dry seasons the llamas find it difficult to obtain sufficient food on the journey.

POWER. Because of the scarcity of fuel and its consequent high cost, various means of generating power have been attempted. Steam, generated by burning *taquia*, *turba*, *yareta*, coal, or oil, is used. Anthracite

gas-producer engines have been employed, and Pelton water-wheels have been installed. However, at present, the majority of the large producers are using the Diesel engine, from which electric energy is generated. It is my belief, already stated, that hydro-electric equipments will prove the future source of power for Bolivian mining operations, and it would not be at all surprising to find my prediction of some four years ago regarding the electric smelting of tin ores borne out by the erection in Bolivia of smelters operated by hydro-electric plants.

FUEL. The scarcity of fuel forms one of the chief difficulties of Bolivian mining. Even if coal could be delivered to Coast points at a low figure, the railroad rates from the ports to the interior are so exorbitant that they have the effect of raising the cost of coal \$20 to \$30 per ton by the time it reaches Bolivian railroad points. Australian coal costs about \$12.50 per ton at Coast points. This prohibits the use of coal as a means for generating power. The Peruvian oilfields suggest a near-by source of fuel. However, it costs less to import California crude-oil than to buy the Peruvian product.

LABOR. Native Indian labor of both sexes is used in the mines and in the mills, while the majority of the superintendents and mine managers are Europeans. The wages of ordinary Indian labor vary from 40c. to \$2.40 per day, the average being about \$1. The Indians are natural miners and if the fast-days were not so frequent, these laborers would prove satisfactory. There is a scarcity of labor, however.

COSTS. Generalizations regarding working-costs are of little value, and my disinclination to publish more or less confidential information prevents me from giving detailed figures. Further, in view of the present unrest among Bolivian mine-owners caused by the discussion of the so-called 20% law, I do not care to be quoted as having stated the actual cost at any one locality. My observation of cost-sheets of mines in widely scattered localities and operating under diverse conditions shows that the total cost of mining, milling, freight, duties, commissions, insurance, etc., ranges from 14 to 38c. per pound of tin contained in the barilla laid down in Europe. This does not include the smelting charge; and it is to be remarked that only under exceptionally favorable conditions can tin ores be placed on the European markets at the low cost of 14c. per pound of metal. The average is considerably higher.

NICKEL-COPPER matte shipped from the Sudbury district of Ontario during 1916 is estimated to be worth \$28,000,000 before being refined, a large increase over previous years. The nickel is worth \$20,000,000 and the copper \$8,000,000. After refining in New Jersey the nickel should be worth \$30,000,000 and the copper \$12,000,000. Refineries may be built in Canada by the International Nickel Co.

Idaho's output of lead in pounds is about equal to Montana's annual output of copper, but the average price of lead is only about a third that of copper.

Engineering Education in the United States

By Charles S. Howe

ENGINEERING EDUCATION is an outgrowth of the idea that men may be prepared in a school for any trade or profession. This idea has arisen from time to time in the minds of some men engaged in various branches of work, but has been very slowly accepted as a general truth. In considering the application of this idea we must remember that a school is a place where something is taught and a teacher is a person who teaches something to one who does not know it. Engineering may have originated in military necessity or have come about through the overflowing of the Nile, but in either case some practice in the subject has in every country preceded systematic instruction. Without attempting to give a history of the progress of engineering, it may be said that the building of roads, bridges, and other structures was of necessity taken up by armies long before schools were established.

The history of the development of all professional schools has been practically the same. The first law-school in the United States was established in 1784. Previous to that, and even for many years after, the young man who desired to become a lawyer apprenticed himself to a practising attorney and acquired his whole knowledge of law from what he could learn in the office and in the courts. At the present time hardly anyone would think of studying law in this way. The opportunities in law-schools are so much greater than they can possibly be in a lawyer's office that the legal aspirant now attends the former, where he can get a diversity of knowledge utterly impossible to gain from one attorney. In like manner young men who desire to become physicians studied with a physician, were quizzed by him, and practised with him for a number of years until they were deemed worthy to practise by themselves. At the present time no young man studies medicine in this way. It is impossible for any one practitioner to give the young medical student all the things that he must have in order to pass the State medical examinations and to practise on his own account. This diversity of training, and especially the laboratory practice now necessary can only be obtained in a school.

Fifty years ago it was thought that engineering must be studied in a similar manner; that a boy must work with a civil engineer or with a mechanical engineer or go into a mine in order to learn anything about his profession. Today the great majority of students who study engineering do it at a technical school because through the breadth of the courses and the opportunities in the

laboratories they are able to secure a broad training that cannot possibly be obtained in any other way. Not long ago business men would have laughed at the idea of teaching business methods and principles in school, and yet today hundreds of young men in Wall Street offices are studying business in school and are taught by college professors.

Up to the year 1862, the schools in the United States where an engineering education could be obtained were few and had a limited number of students. Not many of these schools had a four years' course and the curricula were very meagre as compared with what they are now. Nearly if not quite all of the work was in the line of civil engineering. In 1862, Congress passed the Morrill Bill which provided for the "endowment, support, and maintenance of at least one college in each State where the object shall be, without excluding other scientific and classical studies and including military tactics, to teach such branches of learning as are related to agriculture and the mechanic arts." This was a wise and far-sighted measure. Up to that period few, if any, of the colleges in the United States required any science for entrance; most of them gave very little scientific instruction, and almost without exception there was no laboratory work in any science. A measure which, in spite of this practice on the part of the colleges, required instruction in agriculture and the mechanic arts, thus providing for strong courses in applied science, was almost revolutionary and in the light of recent events must be considered as dictated by the highest wisdom. By means of this measure the State universities then in existence established agricultural and engineering courses and many State universities have since been established with these courses as a part of the regular curriculum. The term "mechanic arts" has been interpreted in most cases to mean "engineering or scientific education."

The demand for men to originate methods and supervise construction, to apply science and natural laws to manufacturing, railroads, mines, and chemistry, was the impelling cause that led to the establishment of courses in engineering.

Previous to the Civil War our development along most of these lines had been comparatively slow and the schools then established seemed sufficient to meet the needs of the slowly growing industrial arts, but during and after the war progress was so great that methods of education and training which before had been sufficient became entirely inadequate and the introduction of these schools not only opened a new era in education, but also brought into the field of industry many men with such preliminary training that they could make rapid prog-

*Abstract of a paper read before the Cleveland Engineering Society and published in the proceedings of the Society in May 1916.

ness in the industries with which they were connected.

The growth of these institutions has been rapid. In 1862 there were but six of them in existence and the total number of students was not more than 300. At the present time there are over 100 engineering schools and the total number of students is about 25,000. Some of these schools are privately endowed and teach engineering only. Some are engineering departments in privately endowed universities and some are definite parts of State universities. The courses and methods of instruction in all of them are essentially the same and hence they may be discussed together.

The problems that these schools have had to meet have been new and difficult. They are professional schools, but their work has been much harder to organize than that of most such schools. Schools of law and of medicine take students either from the high-schools or from the colleges, but in either case they do not attempt to give a broad education nor to teach the subjects usually taught in college. They may, therefore, devote their whole time to the special subjects in which it is their province to give instruction. But the engineering schools are on an entirely different basis. The great majority of their students are high-school graduates, but before they can comprehend the professional subjects which they wish to learn, it is necessary to give them instruction in higher mathematics, English, chemistry, and physics, and in most cases it is deemed necessary to give instruction in at least one modern language. The time, then, devoted to purely professional work is not so long as in the case of other professional schools. It has been difficult to preserve a proper balance between subjects that are sometimes considered as purely cultural and those that are distinctly professional. In making up the curriculum it has been necessary to keep in mind what the graduate will be required to do, and the qualifications for success. Engineering education does not produce engineers. It merely gives to young men that thorough fundamental training which will enable them to become engineers after they have had a few years of practical experience.

An eminent engineer, who has been at the head of a great industrial establishment, has said that the engineer of today should be accurate in his calculations, thorough in his investigations, logical in his deductions, lucid and concise in his statements. He should have untiring energy and alert mind, an abundant initiative, and reasonable self-confidence. He should be absolutely honest in all his dealings, truthful in all his statements, loyal to his clients, faithful to his employer's interests, considerate of his subordinates, diplomatic in his negotiations, and tactful in all his relations. While the college cannot give a man all of these qualifications, it is evident that it can assist in the development of many of them and can show the student the necessity for all of them. To accomplish these results the student must learn certain things: he must learn where to find other things and he must learn to use in the best possible way both his present knowledge and that which he will here-

after obtain. It has been exceedingly difficult to determine just what things the student should learn.

One of the gravest problems that technical education has to face today is whether the student shall be given a broad general training or whether this training shall be limited and the courses highly specialized. Those who contend that a broad general course should be given believe that such a course is the proper foundation not only for that general culture that is so beneficial to every man for his own satisfaction and in his relations to others, but for all future intellectual progress. They believe that this broad foundation should be the basis of all engineering work and that the man who has it is able to take up any subject and rapidly become skilled in it whether he has studied it in college or not. They contend that it is far better to give this broad training with very little specialization than it is to cover a large number of subjects, which may be of special practical value, but for which a man is unprepared because of lack of the proper ground-work. It is particularly advantageous, the advocates of this method say, for a man to finish a general college course before entering a technical school. During his college course he learns how to study; he decides upon his future career; he trains himself in language, in mathematics, in English, which are especially advantageous to him in engineering studies; and his mind is developed to such an extent that he can meet the problems which will come up in the engineering school or in engineering practice, with far more ease and ability than can the student who has merely had the professional training.

On the other hand, the advocates of the specialized courses would give a moderate amount of the subjects named above and would then permit the student to specialize so that he might determine when in college whether he would become a sanitary engineer, a railroad engineer, a shop-superintendent, or an analytical chemist, etc. It is claimed by those who favor this method that specialization has reached such a point that a man, to succeed, must give his attention to one narrow branch of work—that the college is the place for him to study the theory of his specialty and to obtain so much laboratory practice that he will readily become expert in his branch after he leaves the institution. Our engineering schools are divided between these two theories. In a few of our universities the engineering work is a post graduate course, but in a great majority of our technical schools students are admitted directly from the high school. The future must decide whether those who first finish a college course and later take up the professional courses in engineering will succeed better in engineering practice than those who have had the more limited education.

As to the more prominent divisions of engineering education to be pursued there is general accord. These divisions are civil engineering, mechanical engineering, electrical engineering, mining engineering, and chemical engineering. A few institutions offer but one of these courses, while the majority of our colleges offer all of

them. Each course comprehends a number of subdivisions and every year sees an addition to this number. In the early days of engineering education, civil engineering was the only branch taught. Later the development in the manufacture of machine-tools and steam-engines necessitated courses in mechanical engineering. For some time after the application of electricity to practical things this subject was taught as a part of mechanical engineering, but within the past 25 years almost every institution offering engineering courses has provided a special course in electrical engineering. Mining engineering courses have always been divided into mining engineering and metallurgical engineering, while chemistry, which was formerly merely an analytical subject, has now united with engineering processes and developed into a chemical engineering course. It is an exceedingly difficult thing to decide what subjects shall be taught, for the number of them increases with great rapidity and if all are to be given the prominence which their advocates expect, our engineering courses will have to be extended from four to six or even eight years.

Laboratory work has always been an essential part of engineering education. Before 1865 hardly any American college gave laboratory work even in chemistry. From the first the engineering schools have insisted that practical application should accompany theory in every subject. The engineer's work is essentially practical—he must do things, and he cannot learn to do things by simply studying theory. The latter must be connected with practice so that the laws upon which theory is founded may be used to accomplish engineering results. At the present time every engineering school has extensive laboratories, not only in the science, some of which are the basis of engineering, but in the engineering subjects themselves. It is on account of the training which the student receives in the laboratory that he is able to apply natural laws and scientific methods to the work which he will take up as soon as he graduates. Perhaps in some institutions the laboratories are too extensive; perhaps too much detail is insisted upon in some branches, but the principle of the application of the theory is an essential one in engineering education and has been largely responsible for its rapid development and for the success of those who have pursued it.

But no matter how many subjects we teach, there are always some that cannot be taken up by any student. The student who has specialized in one subject in the engineering school may find himself pursuing an entirely different line of work after he graduates, or he may find that in his own specialty there are developments which were not known at the time when he was a student or for which he did not have sufficient time when he was within the college walls. It is evident, then, that every engineer, after he leaves the college, must use many things which he did not learn when in college. For this reason it becomes important to teach him where to find things he does not know. Engineering books, encyclopedias, the reports of societies, engineering magazines, all contain a

vast amount of material that may be of use to an engineer, and in fact, must be used by him from time to time in order to carry out the most recent practice of his profession. To a certain extent the use of this material is mentioned in the engineering school. It has always seemed to me, however, that this development has not reached that point which it should—for a student ought to learn where to find anything within the realm of knowledge. If he has not done so there is much which is known to some one but which is hidden from him. It is evident to every thinking person that the successful man must use what others have done and that college, which has taught the student where to find anything that he may need, has given him a most important part of his engineering training.

But knowledge, whether in the memory or hidden in books or periodical literature, is of no benefit to the engineer unless he has been taught how to use it. The most important thing which the engineering schools are trying to do is to teach the students to think; to see the connection between what they know or what they may find out, and the special problem which has come to them for solution; to determine not only how to do a thing, but to do it in the best way from an engineering standpoint; to do it in the way that will succeed commercially as well as scientifically. It is much easier to hear a man recite or to lecture to him than it is to teach him how to use the thing that is being presented. There are no general courses on thinking; there are no perfected rules of initiative; there are no known methods of teaching common sense. These things come to a student through his own study; from his own thought. He must be gifted with certain faculties of mind if he is to use to the greatest advantage those things which the engineering school presents to him. The school may help him to develop these faculties, and every course properly presented does assist in training them, but no professor, no laboratory, can create these faculties.

Engineering education means four years of discipline. In its highest development this is mental, moral, and physical. The mental discipline I have endeavored to describe; the moral discipline stands out in every recitation, in every laboratory course, in every instructor. If science and engineering teach anything they teach the student to look for the truth and to be satisfied with nothing else. They teach him to shun the shams, to have no pre-conceived notions, to look at both sides of every question, and to accept in his engineering work only that which can be proved. Such teaching as this strengthens the moral fibre in any character and reacts upon every phase of the student's life. Although sometimes unwritten, there is a code of professional ethics in every branch of engineering which the engineer must live up to if he is to be at peace with his fellow workers. Unfortunately we cannot enforce such a code of ethics by law as is done in some foreign countries, but the opinion of the profession at large has done much to prescribe honest practice as between engineers and between the engineer and his client.

Outcrops and the Prospector

By William H. Storms

A KNOWLEDGE of geology, and still more of mineralogy, is valuable to the prospector. It is strangely true, however, that some of the greatest mines of the world were discovered by men having knowledge of neither geology nor mineralogy, but there are also numerous instances where, had these men had even a rudimentary knowledge of the science they would have located more wisely, thereby saving much expensive litigation over mining rights.

What well-informed prospector today, having found gold at the mouth of Gold canyon, would be ten years in discovering the Comstock lode? And yet, this was the length of time that elapsed between the finding of gold in 1848 by Mormon campers near the present town of Dayton, and the discovery of the gold-bearing outcrop on Gold hill. The experience of the placer miners who worked in Six-Mile canyon was identical, for the Ophir outcrop was discovered at about the same time that the find was made on Gold hill, after ten years of placer operations in the gulches below the great lode. In these days the Comstock would have been discovered and located from end to end within a week after the finding of placer-gold and miles of territory on all sides of it would likewise have been claimed by wide-awake prospectors.

Again, it is unlikely that miners sluicing and getting good pay, but finding a heavy light-gray sand constantly filling the riffles and interfering with the saving of the gold, would be years in discovering that there was lead carbonate in the neighboring hills, as was the case at Leadville, in 1866. At that time the place was known as Oro City and the placers were highly profitable, but it was not until about 1876 that lead-silver ore was found on the slope of Carbonate hill. Soon after this the mines were extensively developed and produced prodigious amounts of silver and lead, but it was many years before the presence of oxidized ores of zinc was recognized. The same may be said of the discovery of zinc carbonate at Cerro Gordo, in California. It is not long since the miners near Nome, Alaska, threw away a large fortune in tungsten that was found in abundance in their sluices. The tungsten occurred as scheelite, in the form of pebbles and sand, and gave them not a little annoyance by packing in the riffles. Some of that ground may be reworked now to recover the tungsten ore, and at present prices it may pay well to do so. These are but a few of many similar instances, all of which go to show how essential an elementary knowledge of geology and mineralogy is to the prospector. In the case of the Comstock it was the necessary geological knowledge that was lacking; at the other localities cited, it was the failure to recognize common minerals.

The question naturally arises, can a prospector form a definite idea of the probable value of an undeveloped vein or deposit, from a mere inspection of the outcrop? In many cases the experienced prospector can; but what of the novice, what shall guide him in his search? He has taken up a novel occupation. He may have had no experience or instruction in mineralogy or geology, and yet, such men as these have discovered some of the world's greatest mines. This is known to be a fact, but men of the same calibre have located thousands of claims that were not worth the trouble it took to write the notice, or to even blaze the discovery-tree and scrawl thereon the notice of location.

Outcrops vary greatly in size and appearance. Some are great masses of heavily mineralized silicious rock, standing boldly above the surface, as at Broken hill; others form no striking topographic feature, as at Tonopah, and therefore attract little attention from the casual observer. Still others are small and obscure, but they may be rich. In some places the vein is mantled by a heavy gossan of iron and manganese oxides—black, ragged, and forbidding in aspect; in others the outcrops consist of large masses of quartz, gleaming white and usually worthless. Sometimes the outcrop is so nearly like the adjoining country-rock as to remain unnoticed, until discovered by accident. Some of the ore of the noted Yellow Aster mine, in Kern county, California, is to all appearances an ordinary granite-porphry, exactly like that which is worthless.

So varied are outcrops that an attempt to say which kind has proved to indicate the most valuable mines would probably fail. There are some kinds, however, that may usually be relied upon to supply a large amount of ore, though possibly too low in grade to be profitable. Still, this is only relative, for, by change in conditions, particularly in transportation facilities, the low-grade orebody of today may become the dividend-payer of tomorrow. There are numerous great and profitable mines being operated on a large scale that would be disastrous failures if worked in a small way. Examples of these are found in some of the great low-grade gold mines of Alaska, the copper mines of Bingham, Utah; Ely, Nevada; and Chino, New Mexico.

Outcrops distinguished by extensive iron mineralization are usually indicative of large masses of sulphide ore in depth. Many noted copper mines have a large iron-oxide outcrop, or gossan; for instance, the Iron Mountain and Mammoth mines of Shasta county, California. The former was originally worked for silver. Another example is furnished by the Ducktown mines of Tennessee, which were first worked for iron. Mount Morgan, in Queensland, Australia, though always a gold

mine, is now a large producer of copper, derived from bodies of sulphide ore found at depth. The outcrop of this mine was a silicious brown iron ore, rich in gold. The great copper-bearing lodes of Ely and of Chino contain very little copper at the surface that would attract the attention of a prospector unfamiliar with that type of deposit. The copper lodes of Butte, Montana, present merely rusty-looking outcrops of granite. In few places is there evidence at the surface of the great amount of copper lying in depth. Outcrops of this description would hardly be called 'gossan.' Numerous similar instances occurring in various parts of the world may be mentioned, but those mentioned are typical.

Silver and lead-silver mines are frequently distinguished by heavy outcrops of silicious black oxide of manganese. There were a number of such at Leadville, at or near the surface. What is known as the Rainbow lode, at Butte, on which are the Lexington, Alice, Moulton, Alagna Charta, and other noted silver mines, belongs to this class. Among the famous mines of this type are those at Broken Hill, in Australia. The Bunker Hill & Sullivan mine, in the Coeur d'Alene, Idaho, is another. It is said that the discoverer, a man named O'Rourke, had been following float up the hillside through thick brush and over fallen timber, when he came upon the huge outcrop, he was so astonished at its dimensions and great prospective wealth that he sat down on a log for half an hour or more to contemplate his discovery and decide what he had better do. He finally returned to his partner in camp without having even put up a notice, forgetting all about it in his excitement. This, as a general procedure, is not to be recommended, and the more valuable the property the more foolish would such neglect be. Every prospector should provide himself with copies of the Federal and local mining laws, and he should follow out every requirement of these laws with scrupulous exactness, for the more valuable his mine proves to be, the more necessary will it be to secure his title, and too often, with all the painstaking care he may exercise, the prospector will find certain forceful individuals who will endeavor to find some way to get hold of his find. In the early days gun-plays were of frequent occurrence over the discoveries of rich mines, and they are not wholly unknown today.

The outcrop of the Comstock lode at Virginia City and Gold Hill, Nevada, consists of a series of iron-stained projections of quartz running along the lower slopes of Mount Davidson. From Cedar hill on the north to Gold hill on the south, many of these veins along the foot-wall of the great lode still may be seen, resembling giant walls falling into decay. Near Gold hill there remain thousands of tons of low-grade gold ore outcropping in rough silicious masses. At Tonopah, on the west slope of Mount Oddie, may be seen the remnants of the once extensive hard silicious outcrop veins that first attracted the attention of Jim Butler, the lucky discoverer.

The Homestake mine in South Dakota covers some of the largest bodies of gold ore in the world, yet no bold outcrop marks these immense deposits, and never did.

The formation is hornblende schist, which in places near the surface is altered to chlorite schist. The hills are not abrupt, and the great lenses of ore at the time of the discovery did not look unlike the surrounding rock. All the ore in the mines, and the adjacent country-rock as well, was red—schist and quartz alike—by reason of the iron oxide derived from the oxidation of iron sulphides and partly from the iron minerals of the original rock. The discoverers were guided to the outcrop by the finding of gold in the gravel of the neighboring gulches tributary to Gold Run. There are numerous places in the Black Hills, in Arizona, in Nevada, in Southern California, and elsewhere, where similar formations appear—practically identical in appearance with the Homestake, yet most of them are without value.

The line of the great Mother lode of California is indicated by large lenses of white quartz, and still larger masses of ankerite, but for the most part, these outcrops are not valuable for their gold content, and the most prominent and productive mines, as a rule, have not had prominent quartz outcrops. Generally the richest ore-shoots on the Mother lode do not outcrop at the surface, but are found several hundred feet underground.

Large white outcrops of quartz are common, but ordinarily they are valueless. Near Custer peak, in the Black Hills, is a mass of quartz over 100 ft. wide and about 3000 ft. long. It looks like a huge snowdrift in the summer time, so white is it, but, as far as known, it is destitute of gold. It is called the Standing Horse, but whether so named by the Indians or the miners I do not know. Four miles south of Prescott, Arizona, is another big outcrop of white quartz, but it, like the other, is practically barren. It is known as Quartz mountain. These great masses of white quartz occur in many places, but few of them ever prove to be of value for gold or for anything else unless they are close to the railway, in which event they may have economic value for the making of glass or similar uses.

In the Lava Beds mining district, in San Bernardino county, California, about 30 miles east of Daggett, is a vein that would attract the attention of any prospector, experienced or otherwise. The locator of this great vein noticed its dark wall-like outcrop from a range of hills 20 miles away, while prospecting. Having found nothing encouraging where he had been searching, he decided to cross the intervening desert valley and investigate this, which to him seemed to answer to the descriptions he had read of the Great Wall of China. On nearer approach he found it to be a huge vein, and not a dike, as he had feared it might prove to be. Rising at its eastern end from the desert detritus, it extended for 8000 ft. without a break except where displaced for a few feet by dikes. It stood from 10 to 80 ft. above the surrounding surface and from 10 to 100 ft. in width. It was cut by two canyons to a depth of 800 ft. It is an immense vein and structurally a beautiful one, but the ore is mostly too low-grade to be profitable, though there are rich places here and there along its course. I have seen silver chloride ore from this vein that was worth

\$4000 per ton, but I also saw plenty that is not worth \$4 per ton. It also contains a little gold, lead, and copper. Westward it ends as abruptly as the side of a house, nor has its continuation—if it ever had one in that direction—ever been discovered. The country-rock of this vein is quartz-porphry.

The recent demand for industrial minerals has made desirable a knowledge of the mode of occurrence of manganese, chromic iron, magnesite, cinnabar, and the tungsten minerals; in fact, such knowledge is absolutely necessary to the prospector, if he hopes to discover deposits of these minerals; so I add further notes concerning them.

Not long ago I had occasion to inspect a property on which it was said a deposit of magnesite occurred. I visited the place and near the base of the hill found several small pieces of magnesite that seemed to be of fair quality. It was raining at the time, but I went up the hill and began to hunt for the magnesite deposit from which the small pieces had come. I searched for some time, but all I could find was some white calcite and a quantity of porcelain-like silica. I found no magnesite. The following day I visited another place where there was an outcrop of magnesite. Returning to town, and having nothing in particular to do, I decided to re-visit the place I had inspected the previous day, for I was not satisfied. I felt sure there was magnesite somewhere on the hill. I knew perfectly well that the detached pieces I had found had not come up hill—that somewhere

had it not been raining the first time I would have discovered the magnesite then. Magnesite generally occurs in serpentine, though it is occasionally associated with other rocks, as, for instance, the unusual deposits at Bissell, 20 miles east of Mojave, in Kern county, Cali-

OUTCROP OF QUARTZ AT PORCUPINE, ONTARIO.

formia, where the magnesite is interbedded with shales and thin beds of limestone.

As far as known, chromic iron always occurs in serpentine, there being no known exceptions to this anywhere in the world; therefore, the prospector will look in serpentine areas for chrome and not waste time in a fruitless search for this mineral in limestone, in granite, or anywhere else than in serpentine.

Cinnabar is easily recognized by its brilliant carmine color or streak, but metacinnabarite, which is essentially

the same as cinnabar, as far as composition goes, might easily be mistaken for an iron mineral of some kind. The presence of cinnabar or metacinnabarite may be detected by pulverizing the mineral and concentrating by panning. Place the concentrate in a beaker or in an ordinary tea-cup; add to it a little pulverized black oxide of manganese and then add hydrochloric acid and boil. After boiling several minutes, dilute with water and immerse in the solution a piece of perfectly clean copper. The copper may be prepared by first dipping in nitric acid. When the copper is dipped in the solution, if any mercury is present it will be precipitated on the surface of the copper. Meta-

cinnabarite is not a common mineral, and where it does occur there is usually some cinnabar with it. In California the ores of quicksilver generally are found at or near the contact of sandstone and serpentine. In fact, this applies to all of the great quicksilver mines of the world. At Almaden, in Spain; at Idria, in Austria; at New Almaden and New Idria, in California, and in China. However, it is interesting to know that ores of mercury also occur in limestone, as at Terlingua, in Texas, and in eruptive rocks, as in Nevada.

The prospector is particularly interested in finding

OUTCROP OF BULLFROG LODGE, IN NEVADA.

above, on that hillside, I would find magnesite if I looked carefully enough. This time I went farther up the slope, and noticing an outcrop of black rocks above me went up to them, whereupon I discovered that the outcrop was a body of magnesite from 4 to over 20 ft. wide. The black color was due to a covering of moss. Wherever the rock was broken by my hammer the snow-white magnesite appeared beneath. It was only the knowledge that the pieces I had found the day before must have come from some higher point that decided me to make a second visit to the place, with the result above stated. Probably

ores of tungsten at this time. The principal tungsten minerals are wolframite, manganese-iron tungstate; hübnerite, manganese tungstate; ferberite, iron tungstate; and scheelite, calcium tungstate. The first three minerals are grayish to brownish black. The last is white, yellowish, brownish, or sometimes grayish like bluish quartz. The general appearance of scheelite is that of feldspar. It usually presents numerous glistening faces, due to cleavage, which is absent in quartz. All of the tungsten minerals are noticeably heavy, and for this reason alone are likely to attract attention, if found in pieces the size of a walnut or larger. Of course, a handful of small pieces will have the same unusual weight when their mass is considered. Small pieces, though of the same gravity as larger ones, may fail to attract attention to this property of their remarkable density. Where tungsten ore occurs in disseminated grains it is more difficult to detect than where it is found in masses of considerable size. To determine the presence of the tungsten minerals the prospector can apply the same methods he uses to prospect for free gold; that is, by pulverizing the rock and panning. The concentrate then can be tested easily. Tungsten ores are generally found in highly silicious rocks, such as granite, granitoid schist, in rhyolite, at and near the contact of limestone and granitic veins. Tungsten minerals also occur in pegmatite veins, as in some of the New England states, and in the Black Hills. The most profitable tungsten mines in the Black Hills, however, are found associated with the sedimentary formation near the base of the Cambrian, where quartzites and limestones appear to replace the latter. These minerals are frequently associated in veins with the ores of gold, silver, lead, copper, and zinc, though sometimes they are scattered through the country-rocks.

When the rock suspected of containing tungsten has been pulverized and concentrated by panning, the concentrate may then be tested in a simple manner. Place the concentrate in a test-tube, a drinking-glass, or even in an ordinary tea-cup. Add a little hydrochloric acid; if tungsten be present, a yellow powder will form at the bottom of the glass, though this may be discolored somewhat by the presence of iron minerals. Add to this solution a little metallic zinc and the solution will turn blue if tungsten be present, the depth of the color being determined by the quantity of the yellow powder. If only a little, the color will be light-blue. If the amount is considerable, the color will be darker, even to deep indigo-blue. The addition of tin in place of zinc to the solution has a similar effect, producing the blue color. The prospector may have neither pure zinc nor tin, in which case he may substitute a piece of tin-foil, or even scrape a little tin from a bright tin-can, or chip off a little piece of solder. Either of these substitutes will produce the same color as zinc or tin.

When zinc is added to the solution containing the yellow powder, the color will be first blue; then port-wine color; then brown, but if the reduction takes place quickly, as it may with scheelite, the blue color may not

be observed at all, the first color seen being a reddish-lilac, which quickly becomes brown. If tin be used instead of zinc, the first color is blue, then lilac, then port-wine color, which slowly turns to brown. When using this test, allow the solution to stand several minutes after boiling, before adding the zinc or tin, in order that the formation of the yellow powder (the tri-oxide of tungsten) may be complete.

Sulphuric acid, one part acid to two or three parts water, may be used in place of hydrochloric acid with the same results, but the reactions will be slower. Nitric acid, also, will give the yellow powder, but no blue color is obtained by the addition of tin or zinc. Wolframite must be boiled much longer than scheelite, sometimes 10 to 20 minutes. Failure to give it plenty of time may result in no reaction being evident.

SILVER was discussed recently by Thomas W. Gibson, deputy minister of mines for Ontario. As printed in the *Canadian Mining Journal*, Mr. Gibson said in part: "The fact that the present intrinsic value of silver coins is much less than their face or denomination value does not appear to detract from their usefulness, which primarily depends upon their ability to pass from one person to another without demur. That a 50-cent coin, the silver in which is worth, at 75 cents per ounce, only 26 cents, or a 25-cent piece worth only 13 cents, circulates freely at face value is due not only to the coins being legal tender, but also to the circumstance that they were first made legal tender at a time when their nominal and real value much more nearly corresponded than they do now. Use and want have habituated people to the situation, and silver 'change' for a \$5 gold piece is given and accepted without thought, and in many cases doubtless without knowledge, that if the silver and gold were both melted the latter would sell for \$5, while the former would bring only \$2.60. The government that coins the silver and stamps it with its nominal value, profits by the difference. The profit of the British mint in 1913, when silver coinage to a nominal value of £1,934,404 was issued, was £726,926." That is, this amount was the excess of the face value of the coins over the price paid to the miner for the silver.

Production of explosives in the United States, excluding exports, during the calendar year 1915, according to figures that the Bureau of Mines has received from manufacturers, was 460,900,796 lb. (230,450 short tons), compared with 450,251,489 lb. (225,126 tons) in 1914. The report covers only the explosives used in coal and metal mining, railroad construction, and other industrial enterprises. The production for 1915 is segregated as follows: black powder, 197,722,300 lb.; high explosives other than permissible explosives, 235,828,587 lb.; and permissible explosives, 27,349,909 lb. These figures represent a decrease of 8,377,400 lb. of black powder; an increase of 17,374,616 lb. of high explosives, and 1,652,091 lb. of permissible explosives compared with figures for 1914.

Custom Smelters and Small Mines

By J. M. Turnbull

THE average prospector, mine-owner, or manager, and others interested in mining on a small scale, have usually vague ideas in regard to the operations of a smelter. Their ideas concerning the value of an ore are, as a rule, based on the gross returns. If the gross value of the ore, figured on a full assay at market prices of metals, is, say \$20, and the smelter treatment rate is \$5, one would at first sight expect to get a net of \$15, and when, instead, one gets \$8 or \$10, it is natural to feel that there is something wrong, and that all the deductions made by the smelter, which account for the difference, cover a large hidden profit—in fact that one has been robbed. If, however, one knew how these deductions were arrived at, and had an idea as to what deductions were reasonable and justified, and what were not, he would be in a better position to see what kind of a deal he was getting, and judge its fairness for himself.

In answer first to the broad question: Do smelters of custom ores make exorbitant charges, or rob the miner? I have no hesitation whatever in answering "No." In the great majority of cases where the charges seem excessive there is a good reason back of them. This is partly due to competition, and partly, in common with other large business, to the fact that in the long run it pays to be reasonably honest. In exceptional cases exorbitant charges may be made, but eventually they discourage production, on which the life of the smelter depends, and the modern policy is to encourage the producer with fair rates, and so build up a permanent business, in return for the large capital investment involved. While not usually guilty of robbery and extortion, smelters are in business to make a profit, and endeavor to sell to the best advantage. The small miner can hardly expect as good rates as put back in the steady producer, but by knowing something about the business he can often market his ore to better advantage, and get the best contract possible.

SMELTER PROFITS. The A. S. & R. Co., the so-called Trust, did a volume of business in 1915 amounting to \$225,000,000, in which their net profit was some \$13,000,000, or 5% on the turn-over. Of this, however, nearly \$1,000,000 was put back in the form of new construction for 1916. The year 1915 was a good year, and the profits do not look big compared with some of the 'war baby' stocks. The profits were very good, much better than in many former years, but they hardly look like extortion or robbery.

On over 4,000,000 tons the average net profit was

about \$2.25 per ton. In British Columbia our smelters are largely engaged in smelting ores from their own mines, and their total profits are from both mine and smelter, and the smelting profits are not separately given in annual reports. In the case of the Trail smelter, which treats the largest tonnage of custom ore in British Columbia, this represents from 12 to 15% of their total only. I happen to know positively, from my past connection with this smelter, that their rates are not extortionate on custom ores.

Having given the smelters a fairly good character, I shall now take up certain points in connection with their operations and charges in detail. While there is no big nigger in the fence, there are a few small niggers, a knowledge of whom may be of some benefit to you.

SETTLEMENT. Theoretically a smelter operates on the idea that he takes your ore, extracts the pure metals from it, and hands them back to you, charging you a fair price for the work of doing so. In practice this is found to be impossible. Each lot of ore cannot be smelted separately, and its contents kept separate. For economical smelting an average constant mixture must be maintained, so that before the ore ever sees the furnace it is mixed up with other ores, and since ores are received irregularly, some are smelted quickly and others may be delayed some time, in order to keep the furnace mixture reasonably constant. A dozen different ores may be in the furnace at once and the metal produced is merely an average; the average losses can be determined, but no one can tell what the exact loss is on any particular one of them. What the smelter does is to put each lot separately through the sampling-mill and assay the sample, determining the metal content by this assay. The losses can only be assumed in each case from the average loss on all the ores smelted together.

A smelter test on any lot of ore consists of an accurate sampling and assay. There can be no real smelter test on one lot. To ship a carload for a smelter test means therefore that you get an accurate sample, and the smelting quality of the ore is largely judged from the analysis made in the laboratory, long before the ore gets near the furnace. Since metal is produced by the smelter in one lot from many lots of ore, it is practically impossible to separate it into proportionate small lots and hand each mine back its proportion, nor could it be sold in this way to advantage, since metal-selling is a complicated business, based on large contracts, etc., so that the smelter is compelled to act as selling agent. Selling costs money; therefore the smelter always deducts a marketing charge from your ore in some form or other.

Extracting the metal from your ore and selling it takes on the average about three months; therefore, un-

*Summary of informal talk before the Vancouver Chamber of Mines, given by request, for information of prospectors and small mine owners, and published in the *Mining Engineering and Electrical Record*, at Vancouver.

less you wish to wait three months for your returns, the smelter is compelled to act as banker, and advance you the money on the basis of the assay. This means interest charges, which are also deducted from you in some form. The price of metals may vary greatly in three months, however, so that if the smelter pays you on the basis of the price at the time he receives the ore, he may make a profit or loss on the sale of metal three months later, according as the price goes up or down in the meantime.

This method of payment is known as 'spot' settlement. It is not desired by the smelter, since a slump usually occurs when metal prices are high, when everybody is shipping all he can and the smelter is overstocked with ores, so that the tendency is for the smelter to make a larger loss on the slump than his gain on the rising market. To place the risk of gain or loss on the mines, the smelter may make contracts on a three months' settlement, that is, pay 90% spot and adjust the balance on the price of metals three months after receipt, paying you in fact as near as possible on the basis of what he actually receives for the metal. By paying you spot, on a rising market, and switching to three-month basis before a slump, the smelter stands to make an extra profit. The miner's interest obviously calls him to do the opposite, if possible. It is a kind of guessing contest, and the best guesser wins. I need hardly say who is likely to be the best guesser, and the smelter is hardly likely to allow you to switch to your advantage when you please, so that you should not allow him to do so either, which you can accomplish by making a contract over a considerable period, choosing if possible which kind of settlement you prefer, if you can get it. The smelter has the advantage of a better knowledge of market conditions and of not being compelled to accept a settlement he does not desire, while the mine has the advantage of being able to ship heavily or lightly according to conditions on the usual contract. This is one small nigger in the fence, the advantage being rather on the side of the miner, if he knows the game.

TREATMENT CHARGES. In quoting you a treatment rate, the smelter makes various deductions, which are supposed to cover marketing costs, losses in smelting, and so on. Presumably these are the costs and losses actually incurred by the smelter in operation, acting as your agent, and do not theoretically leave any profit for the smelter, that is, from the deductions alone. In addition, a straight treatment charge is made, which presumably covers the actual cost of smelting plus profit. If the smelter makes an unusually low treatment charge, he probably makes up the difference by high deductions, and vice versa. A low treatment charge does not necessarily mean that you are getting your ore smelted cheaply.

In the meantime, what is a fair treatment charge? This depends on the ore, and can only be answered in general terms. On copper ores, with immense tonnages of easily smelted ore, the direct cost of smelting may be as low as \$1.25 per ton, as at Grand Forks. With high-grade concentrates it may run up to \$4, or even more.

On the general run of ordinary ores somewhat about \$3 would not be excessive. Adding one or two dollars for profit a charge of \$4 or \$5 is reasonable in most cases, provided an extra profit is not also made on excessive deductions.

On lead ores that require roasting, as most B. C. ores do, the direct cost of smelting, not including refining, may run as high as \$8 or even more, but it is even more difficult to average than on copper, depending on the grade of the ore, and treatment charge is often on a sliding scale varying from \$8 to \$12, which, including profit, is not excessive if the deductions are fair.

Ore as received at the smelter in railway-cars is first weighed, giving the gross weight, then in turn it goes through the sampling-mill, being crushed, run over samplers, etc., in the course of which it dries to some extent. The sample is taken, part of it is weighed and dried in an oven, and the percentage of moisture determined. From this and the gross weight the dry weight is calculated; the assay is made on the dried sample and payment is made on the dry weight, which is fair and accurate. In the sampling and handling, however, the ore dries somewhat and there is often a considerable loss in dust. To cover these losses the smelter sometimes makes a deduction of about $\frac{1}{2}\%$, which is called 'yard' loss. The loss is real, but just what it really amounts to is hard to determine—impossible, in fact. One must judge its fairness by circumstances. It is, however, not a dishonest deduction in principle—it is a question of amount.

MARKETING CHARGES. What is a fair marketing charge? This is rather a knotty question to answer. Let us see what marketing charges consist of. Refining either lead or copper is usually considered as part of the marketing. Copper refining probably costs about $\frac{1}{2}c.$ per lb. in the East, and somewhat higher in the West, depending on labor and electric-power costs largely, as well as the scale of operations, say, not over $\frac{3}{4}c.$ Freight from the West to New York would account for another $\frac{1}{2}$ to $\frac{3}{4}c.$ Three months interest brokerage and commissions bring the total up to $1\frac{1}{2}$ to $1\frac{3}{4}c.$ for the big fellows, while the smaller smelter might be out $3c.$ or even more. On custom ores the deduction is usually from 3 to $4c.$ per pound. In general, the smelter probably plays safe on this and makes from $\frac{1}{2}$ to $1c.$ per lb. equivalent to from 30 to $60c.$ per ton on a 3% ore. A high deduction on this account is all right if the treatment charge is low by a corresponding amount.

In the case of lead, refining is less costly, being a minimum of $0.2c.$ per pound under favorable conditions of cheap fuel and labor. In the West it might run up to $0.5c.$ Freight would be to the East, where the chief market is, another 0.5 or $0.6c.$, besides selling expenses. The Trail smelter deducts $1c.$ per lb. for marketing, on which it evidently makes no profit. American smelters usually deduct $1\frac{1}{2}$ to $1\frac{3}{4}c.$ on which, with better marketing conditions, they should make a considerable profit, and can make apparently low treatment charges on ore in consequence. There is a mutual tariff-wall between Canada and the U. S. on lead; hence marketing condi-

tions are somewhat artificial, whereas in copper there is free interchange. Lead ores as shipped usually contain from 25 to 70% lead, whereas copper ores run from 1 or 2% up to not over 10 or 15%, hence the marketing charge on lead usually figures out much higher per ton of ore, even though less per pound of metal. It therefore looks much worse than it is. In fact, it is surprising that miners will cheerfully pay 3c. per pound on copper, and yet make vigorous objection to 1c. per pound on lead, which is a much more favorable charge. The reason is probably because it looks worse per ton of ore. The difference is plain.

METAL DEDUCTIONS. Smelters usually make deductions from the metal assay to cover losses in smelting. In the case of copper, losses are chiefly in the slag, and partly mechanical, handling, flue-dust, etc. Slag in the furnace seems to hold a certain minimum amount of copper, varying to some extent with the grade of the ore. Considering all the operations, the loss seldom runs much below 0.3%, and may be considerably more on high-grade ores. We may take 0.3% as a fair average deduction on which the smelter is not making much, if any, profit. Except on high-grade ores, 20 to 30% copper or more, any deduction over about 0.3%, represents a profit for the smelter. In many cases it will be found that the smelter is making a deduction of 1 to 1.3%, usually with a low treatment charge to correspond, since few smelters would have the nerve to make this deduction and a full treatment charge as well.

The reason for making this high deduction is three-fold: First, 1.3% is an old standard deduction that has been adhered to, and the difference made up by reducing the treatment charges.

Second, a low treatment charge looks attractive, many miners scanning that more closely than the deductions; the treatment charge may even be zero, which looks very fine.

Third, the price of copper. The smelter is evidently making a profit of 1% copper, or 20 lb. At 12c. net per lb. the smelter is getting \$2.40 per ton of ore, and at 24c. it is getting \$4.80 per ton. Your treatment charge is automatically rising with the price of copper. Fine for the smelter on a rising market, and vice versa. On the 24c. price 0.3% deduction and \$4.80 treatment is equivalent to 1.3% deduction and zero treatment. In the latter case you are getting your ore treated for nothing, I don't think. The cathode price is ½c. less than electrolytic.

Lead deductions are on quite a different basis, chiefly because lead and lead compounds, unlike copper, are volatile at the usual furnace and roasting heats. Lead smelters make various rates. The Trail smelter pays 90% of the lead; that is it deducts 10% for losses, which losses mostly occur in smoke. Certain American smelters smelt Mexican lead ores in bond and are required to export the equivalent amount of lead metal. The U. S. Government therefore checks them up, and makes an allowance for losses in smelting and refining. In 1914 these were as follows: Balbach, New Jersey, 8.52%; Perth, Amboy, N. J., 22.32%; El Paso, Texas, 18.56%.

This is pretty good evidence. In the case of Trail, I know that the losses are over 10%, that is why they are spending so much money on Cottrell smoke-plants.

As a matter of fact the losses depend on the ores; they are least on pure ores. In Missouri they may be less than 5%, but on impure zinky ores as we have in Canada, in the West, 10% is a fair deduction—more than fair, in fact, in spite of the text-books, which tell you that the smelter saves 93 to 95% of the lead.

PENALTIES AND BONUSES. Lead furnace-slugs can carry about 6 or 7% zinc without much detriment. Above this point the zinc has two bad effects: first, it tends to carry silver into the slag; second, it tends to make the slag infusible and pasty, which results in slow furnace running, greater slag-losses, and difficulties in running, which add materially to the cost and trouble, of which there are plenty in lead smelting in any case, and cuts down capacity. This rapidly becomes worse as the zinc gets higher. With over 12 to 15% zinc it is next to impossible to run the furnace. A smelter that receives low zinc ores on the average can stand a few lots of high zinc without much detriment, and should not charge a high zinc penalty. Where the zinc in ores averages high anyway, extra lots of very high zinc are a serious matter and necessitate a high penalty, and even then they are not desired. The usual penalty is 25 to 50c. per unit (1%) on all zinc over 8 to 10%.

SILICA, IRON, AND LIME. In order to run a furnace properly the smelter must keep an even balance between silica on the one hand and iron and lime on the other. If he cannot get this balance in the available ores, he is compelled to make it with barren fluxes, such as quartz iron ores (free from sulphur, if possible) or limestone. Few smelters can get an even balance, or self-fluxing mixture, from ores only, and have to offer special inducements in order to attract the kind of ore they need, and make it possible to ship low-grade ores of the needed class, by offering a bonus on the kind of material they require. At the same time they usually charge a penalty on ores of opposite character.

The proper method is to have the penalty and bonus equal and opposite, usually 5 to 10c. per unit, payable or chargeable on the excess of one side over the other, that is, silica excess over iron plus lime or vice versa. One or two little jokers may occur here. Where the silica excess is penalized, the contract sometimes forgets to mention the lime and refers to iron only, so that too much penalty is paid. Sometimes the penalty is made larger than the bonus, and all the silica, say, is charged with penalty, and all the iron and lime credited with bonus. In the case of an ore running even there should be neither penalty nor bonus, but by this joker, if there is, say, 30% of each, you pay 30 by say 10c. penalty and get only 30 by say 7c. bonus, a difference in favor of the smelter of 90 cents per ton.

Instead of silica, the contract may specify 'insoluble,' which means merely that portion of the ore insoluble in acids, which may be considerably higher than the true silica in some cases.

Gold-Scheelite Ore in New Zealand

By C. W. Gudgeon

*In Otago, in the South Island, gold and scheelite ores occur at Macrae's and Glenoreby in Waihemo and Lake counties, respectively. At the former centre is the Golden Point mine, developed by adits. In it are three parallel lodes, running conformable with the altered zone strata, and separated 15 and 25 ft. They are much faulted and are difficult to follow. Careful timbering is necessary. The top lode, No. 1, 3 to 4 ft. thick, is low in gold and tungsten, but has odd pockets of rich ore. No. 2 is 3 to 6 ft. thick, contains 0.5 to 1 oz. gold, and is highly impregnated with scheelite, with pockets of almost pure mineral. No. 3 is small and of no importance. The gangue is quartz; the country-rock is mica schist, lying horizontal. Driving is cheap owing to the soft schist, as low as \$1.44 per foot for a 4½ by 6-ft. drift. Underground work costs \$1.86 per ton.

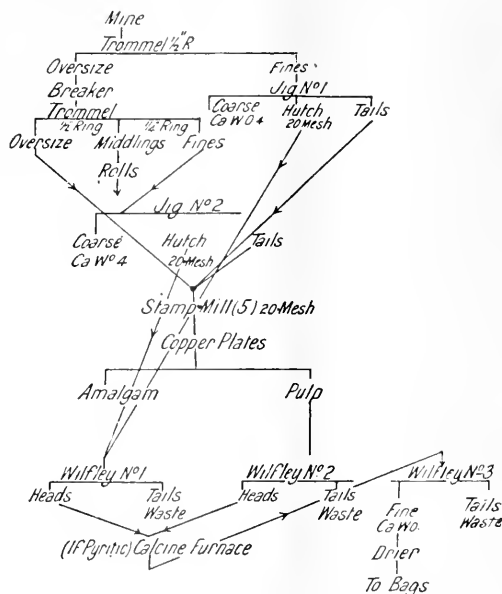

Ore treatment consists of hand-grading the best ore to 60-65% WO_3 , which is shipped. The lower-grade ore is crushed at the rate of 30 tons per day through 30-mesh by ten 900-lb. stamps. Copper plates save the coarse gold. The pulp is classified and passed over Wilfley tables, which concentrate out the scheelite. Sand is cyanided in vats by percolation; the slime is stored. Amalgamation saves 46% and cyanidation 36% of the gold. Increased depth of mining gives scheelite associated with iron pyrite. The concentrate contains 30 to 40% CaWO_4 (scheelite), 50 to 55% pyrite, 10% silica, and 2½ oz. gold, and is equal to 0.5 to 1% of the ore milled.

Concentrate treatment consists of drying the product in a cylindrical outside-driven roasting-furnace. During this process the calcined concentrate is elevated and dropped 8 ft., with free access to the air. Roasting is done as far as the magnetic sulphide stage. The concentrate is next separated electrically, making an iron-gold and a scheelite product. During this separation 15% of the scheelite and 21% of the silica is detected over with the magnetic iron, while running on high amperage. This iron product is submitted to re-treatment and re-roasting, giving a clean iron product containing 5 to 6 oz. gold per ton, and 73.1% CaWO_4 , equal to 61.2% WO_3 . Concentrate high in silica is reduced to 10% or under, before separation, by jigging. Total treatment charges are \$1.38 per ton of ore milled. All costs were \$3.53 per ton.

Five miles north-west of the Golden Point mine is the Highlay, which was worked-out in 1913. The coarse hard ore was crushed by five 800-lb. stamps, while a 5-ft. Huntington mill reduced the finer and softer material. These machines were followed by copper plates. Fine vanners for the soft and Wilfley tables for the hard ore. Sand was cyanided, and slime run to waste. For many years the mill treated 1000 tons per month, averaging

0.28% WO_3 and 42c. gold per ton. Costs were 90c. for all departments.

On Mt. Juda, 240 miles north-west of Dunedin, the Glenoreby Scheelite Mine Co. is operating. The lode is in metamorphic schist similar to those at Macrae's, but the schist is harder and more crystalline. The mine is opened by drifts from the surface, along the pitch of the orebody. The gangue is a dense quartz, and has associated with it gold, scheelite, iron, and arsenical pyrite. The scheelite occurs in the ore-channel in distinct layers, irregularly

FLOW-SHEET OF GLENOREBY GOLD-SCHEELITE MILL, NEW ZEALAND.

spaced, through the barren lode-matter. The lenses are high in scheelite, and are very pyritic in the sulphide zone.

The present scheme of treatment, shown in the accompanying flow-sheet, gives good results. As little crushing is given as possible, as the scheelite is so friable. If pyritic, the concentrate is roasted and re-dressed to 70% WO_3 . As the iron tailing is low in gold it is discarded. From 5400 tons of ore the recovery averaged 7.09% WO_3 and 45c. gold per ton. Costs total \$5.52 per ton.

The following is a reliable assay of pyritic-scheelite concentrate: Take 10 grams of material and grind in an agate mortar. Digest in aqua regia and evaporate to dryness three times. Take-up with hot H_2O and boil. Filter. Wash with hot H_2O till free of all chlorides. Wash with hot dilute HCl . Dissolve the CaWO_4 with hot ammonia. Evaporate to dryness. Ignite, and estimate as WO_3 (tungstic oxide).

THE SAN FRANCISCO MINT in June received 201,019 oz. of gold and 63,857 oz. of silver. Gold sold amounted to 52,214 oz. \$24,000 in nickels and \$2700 in pennies were coined. The vaults contain \$370,628,914.36.

*Abstract from Bulletin 21 of Aust. I. M. E.

The Demand for Quicksilver

The domestic quicksilver industry has continued active during the first six months of 1916, and the average price for the period has been about double the exceptionally high figure for the entire year 1915. Figures just compiled by the U. S. Geological Survey show that the total production of quicksilver in the United States in 1915 was 21,033 flasks of 75 lb. each, having a marketed value of \$1,826,912, or an average of \$86.86 per flask. Of this output 14,283 flasks, selling for \$1,174,881 came from California, and the remainder almost entirely from Texas and Nevada. The actual average sales value for the whole country exceeded the average market value in San Francisco—which was \$85.80 for the year. In 1914 the domestic output was 16,548 flasks, valued at \$811,680, and therefore the production for 1915 showed an increase of over 27% in quantity and 125% in value.

The increased domestic demand for quicksilver in the last 18 months has been due mainly to war requirements for fulminate and drugs. Early in 1915 domestic stocks began to be drawn upon and production became more active, but as foreign embargoes left the field clear and domestic output was unable to meet the rapidly increasing call for the metal, prices continued to rise throughout the year and into the early months of 1916, the high mark of \$300 per flask being passed in February. Naturally every mine and prospect became of interest. The reaction set-in, however, as the high prices drew out quicksilver supplies in Mexico and elsewhere that had been originally purchased for amalgamation of gold and silver ores, and finally as the British government permitted exports to America under certain limitations. The average monthly domestic price in San Francisco, which had climbed from \$51.90 in January 1915, to \$295 in February 1916, dropped to \$219 in March, \$141.60 in April, \$90 in May, and about \$72 in June. The market remains steady and in general highly profitable, and as domestic prices have dropped below London quotations, exports rather than imports of the metal may be expected. There is probably no great quantity of metal stored, and consumption is undoubtedly abnormally large.

Favorable markets have brought out great activity in search for new prospects, and discoveries near Morton, Washington, and Beagle, Oregon, in 1916 have led to some development and construction of reduction plants. Also in the Skull Valley deposits, Arizona, referred to many years ago by W. P. Blake, and at Black Pine, Idaho, some activity is reported. Many old furnaces have been repaired or enlarged in California, Nevada, and Texas, old workings have been re-opened, and new discoveries have been developed.

It is likely that the exceptionally high prices of the last few months have led to gouging and robbing many mines of their best ore, and the average tenor of the ore worked by the larger mines during the first half of 1916 may prove considerably below that of previous years. Moreover, some mines have undoubtedly passed their maxi-

mum productivity. These conditions are probably offset to some extent by the fact that more furnace capacity is now working on quicksilver ores than at any previous time in the history of the industry. On the whole, the mid-year outlook is for an output in 1916 fully equal to that of 1915.

The Big Three

There are three copper producers on the American continent which can each show a net earning capacity of \$40,000,000 or better on a sustained 25-cent copper market: Anaconda, Kennecott, and Utah Copper. In point of volume of output and profit these are America's 'Big Three' in the copper industry. No others are in the same class.

Measured by production, Anaconda, of course, stands at the top of the list, its annual output now running at the rate of 340,000,000 lb. Utah is second with 190,000,000 lb., and Kennecott third with 216,000,000 lb., but of this latter amount, 48,000,000 is represented by the company's 25% ownership in Utah Copper. Excluding the Utah duplication referred to, these premier producers combined are earning at the rate of no less than \$124,000,000 from 700,000,000 lb. of annual output. This production represents over 50% of the total smelter output of the United States in 1915—1,365,500,000 lb. Carrying the comparison a step farther, it will be found that Anaconda, Utah Copper, and Kennecott are earning almost three times the total profits realized from the 1914 production of the whole country, including imports. In that year electrolytic copper averaged 13.30c. for the 12 months and the average cost of production was easily 9½c. per lb. At the outside, therefore, the profits could not have exceeded four cents per pound on 1,150,000,000 lb., or \$46,000,000.

That three properties in 1916 should be able to earn three times what all the mines on the North American continent could produce two years ago, testifies not only to the bigness of each of these three units, but to the sensational profits that are made when copper sells for 25 cents.

There are no other copper mining concerns which can approach the class of the Big Three. Phelps, Dodge & Co. comes fourth with 140,000,000-lb. output when its Mexican property, the Moctezuma, producing 22,000,000 lb., is in commission. Next would come Inspiration with 120,000,000 lb.—*Boston News Bureau.*

THE BUTTE & SUPERIOR mine in Montana mined 591,562 tons of ore in the year ending June 30, 1916. This ore was worth \$31.27 per ton, giving a gross value of \$20,271,949. This makes the Butte & Superior one of the great mines of the world. For comparison the Utah Copper Company's income from copper produced in 1915 was \$26,235,331. The Elba Ore mine, which is adjacent to the Butte & Superior, mined 209,752 tons of zinc ore worth \$18.52 per ton, in the year ended June 30. The net profit was \$495,757.

CONCENTRATES

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

CHISELS are made from steel containing 0.75 to 0.85% carbon, which is about the same proportion of carbon as is contained in drill-steel.

THE FLOTATION PROCESS at Braden, Chile, is saving 80% of the copper from 4000 tons of ore per day. As 10% of the copper minerals is oxidized, this is equivalent to 90% of the copper sulphides.

MEXICAN silver dollars purchased in San Francisco in 1857 by a traveler going to the Orient, where such coins were in regular circulation, cost \$1.30 each in American gold, the price of one ounce of silver at that time.

MERCURY FULMINATE, used in detonators and floating mines, explodes at a pressure of 28,750 kilograms per square centimetre, or 204.45 tons per square inch. Nitroglycerine explodes with less than half of this force.

CYANIDE CONSUMPTION at the Great Boulder mine, Kalgoorlie, Western Australia, where roasting and fine grinding is practised, is 0.96 lb. per ton; mercury loss in the pans is 0.11 oz. per ton. The cost of treatment is \$2.48 per ton.

A BLAST may be delayed as much as an hour by the fuse being bent and the spark retarded. It is not well when loading a blast to bend fuse at a sharp angle; nor is it well to approach a charge of unfired explosive, the fuses of which have been lit within an hour.

WOUNDS should not be treated with mercuric chloride dressings, if iodine has been applied. The consequence would be the formation of mercuric iodide, which is strongly irritating. To remove mercuric iodide, wash the wound with a 10% solution of potassium iodide.

CEMENT-SETTING in drill-holes in mineralized underground waters is not thoroughly understood, and there is considerable dispute about it. One system is to analyze the water and add certain chemicals to neutralize acidity. Many successful well-cementers declare that minerals in the water have nothing to do with it.

MINE-TIMBER in the Passagem mine of the Ouro Preto company in Brazil is treated with lime mixed with a solution of zinc sulphate, a waste product from the cyanide works. This liquor has a preservative effect on the wood. White ants attack some mine-timber near the surface.

CEMENT MORTAR is used on the Canal Zone to plug cavities in trees that might otherwise collect water and serve as breeding places for mosquitoes. A 1:4 mixture is employed for ordinary-sized cavities, while the volume

of mortar needed for large ones is reduced by using pieces of rock in the aggregate. In the city of Panama over 4000 cavities in 1600 trees have been plugged.

METAL is being used to a greater extent than formerly for farm buildings. Barns with steel frames, or covered with galvanized-steel sheeting and equipped with metal ventilating systems are becoming popular. Other farm structures that are being made at least partly of metal include corn-cribs, garages, hog-cots, and silos.

LEAD-PLATED STEEL is being substituted for zinc-plated and nickel-plated metal. It is particularly useful for protection against the corrosion caused by acid and fumes. A new process of lead-plating has been recently perfected by a firm in Cleveland. The lead-plate is said to be cheaper than the zinc-plate or nickel-plate.

NAILS driven in wood that is exposed to alternate wetting and drying are likely to work out. The wetting swells the wood and moves the nail, which does not return to its original position when the timber dries. It is for this reason that timber structures bolted together and exposed to weather require screwing up at intervals.

IN TREATING GOLD ORE worth \$10.11 per ton last year, the Hollinger mill at Porcupine, Ontario, used 0.574 lb. of cyanide, 1.896 lb. of lime, 0.467 lb. of zinc, 0.0032 lb. of acid, and 0.0021 lb. of lead acetate per ton milled. The pregnant cyanide solution averaged \$5.074 per ton. Tailing contained 40 cents per ton. The cost of treatment was \$1 per ton.

SAWMILLS in the United States number over 48,000, and their output of waste in the form of saw-dust, shavings, slabs, and other wood refuse is estimated as 36,000,000 cords per year. Perhaps one-half of this so-called waste product is not strictly speaking wasted, but serves a useful purpose as fuel under the boilers, according to the Forest Service. Much of the remaining 18,000,000 cords not only serves no useful purpose, but in most cases is a source of inconvenience and danger, and costs the mill both time and money.

IMPURITIES in spelter are chiefly lead, iron, and cadmium; traces of arsenic, antimony, sulphur, tin, and copper also are found. In some special brands of high-grade American spelter, the lead does not exceed 0.02%, and iron 0.01 to 0.02%. In good ordinary brands, lead may be 0.4 to 1%, and iron 0.03 to 0.05%. In spelter intended for rolling, a small proportion of lead is desirable, and up to 1% it has no injurious effect on the ductility of the metal. But for spelter used in making cart-ridges, where the mechanical treatment is severe, the content of lead should be as low as possible, not exceeding 0.1%. Iron makes spelter hard and brittle, showing perhaps as grey specks on a fresh fracture. Not more than 0.05% iron is allowed in spelter intended for brass. Cadmium, often associated with zinc, is not harmful up to 0.5% in spelter used for brass.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

FLAT RIVER, MISSOURI

INTERESTING NOTES FROM A GREAT LEAD CENTRE.

The lead district of south-eastern Missouri is very prosperous this summer. The high price for the metal is stimulating production, and a record output is being made. Employees are receiving the highest wages ever paid here, another 10% bonus having been added in April. This gives labor an increase of 30% above that of 18 months ago. According to the local bankers most of the men are saving their money. A rather severe lesson was taught during the panic of 1907; wages were high then and money was spent freely. The entire district is under local option now, which has also aided in a larger saving by the men.

There have been one or two strikes among certain elements of the men. On May 1 the foreigners at the Federal Lead and Doe Run Lead companies went on strike for higher wages and fewer cars to be shoveled per man-shift. They were out for over a week, resulting in the close-down of the Federal mill and consequent idleness of several hundred men as well as themselves. The strike did not spread, and on May 10 they returned to work at the same wage-rate.

At a meeting of the shareholders of the Doe Run Lead Co., held on May 11, it was decided to consolidate with the St. Joseph Lead Co., and to dissolve the Doe Run corporation. A petition to this effect was filed with the Circuit Court, and will be acted on during the October term of the Court.

Construction of the new Federal mill is proceeding rapidly. The building is of concrete and steel on a hill-side, and is practically complete. This is the only mill in the district to use a steep sloping site. An interesting test has been conducted for some time in the Federal mill between Deister-Overstrom, Butchart, and Wilfley tables. The last-named has long been the standard in the district, but during the last year a great deal of interest has been taken in treating large quantities of ore on a single table. As a result, the St. Joseph and Doe Run companies were licensed by Mr. Butchart to fit their Wilfley tables with his rifle system. The Desloge Lead and the St. Louis Smelting & Refining companies are installing Butchart tables in their mills, replacing Wilfley and Overstrom tables. The Federal mill will use tables of each make.

A great deal of option and development drilling is being done in the district. The Baker Lead Co. is drilling the Barber-Turley-Cole tract, north-west of Bonne Terre. Some option drilling has also been done near Des Arc in Iron county. The St. Joseph Lead Co. is shipping slag from an old pile at Bonne Terre to its smelter at Herculaneum for re-treatment. This slag was made 40 years ago, and is high enough in lead and matte to make reduction profitable.

The old silver mines in Madison county are proving to be a surprise for the district. It is reported on reliable authority that a large amount of tungsten is available. The ore-bearing vein has been traced for 1½ miles and is from 2 to 6 ft. wide. In addition to tungsten the ore contains lead, zinc, and silver. A stamp-mill is being erected with tables and a flotation plant.

The Fredericktown district is being opened. The North American Mines Co. will start operation shortly. It has been announced in the local press that the Mine La Motte Co. will build a railroad from its property to the Mississippi river, a distance of 30 miles. It will join the 17 miles of road now

operated by the company. The way has been surveyed, with low grades. The estimated cost of road, stations, switches, etc., will be not over \$500,000. With the rolling-stock now owned, the new equipment will not cost more than \$150,000. This will be of great benefit to the company, as it is now paying \$12,000 per month freight and switching charges, for about 200 tons per day, covering coal and lead concentrate. In addition

MAP SHOWING SITUATION OF MINING DISTRICTS IN SOUTH-EAST MISSOURI.

tion to the present mines, deposits of clay, limestone, granite, and sand become available for market. In connection with the railroad, the company plans to put a barge line in operation on the Mississippi river, to be connected with the railroad by modern wharf facilities. The saving in freight alone will pay the maintenance and operating cost of the railway and barge line.

WASHINGTON, D. C.

SALE OF OIL-LAND BEFORE CONGRESS

Gifford Pinchot has come out strongly against the Phelan bill which disposes of 3,000,000 acres of Government oil-lands in California and Wyoming, withdrawn by ex-President Taft to protect them from monopoly and to await further legislation. The prospect is that there will be a lively fight over the bill. It is familiarly known as the Leasing Bill, and has been reported to the Senate from out the Committee on Public Lands as a substitute for the Ferris leasing bill of the House

of Representatives, which included coal as well as oil and mineral lands. The Phelan bill, strangely enough, excluded coal lands from the operations of the act, an announcement stating that the coal lands would be attended to in a later bill. The additional new feature was the disposition of the California and Wyoming oil-lands mentioned. The conservationists are excited over the prospects of the bill, and Mr. Pinchot announces that he has arrived in Washington for good to combat its passage. The Attorney-General of the United States and the Secretary of the Navy have given testimony in opposition to the oil-land provisions in the Phelan bill, and Mr. Pinchot takes comfort in this, but the Secretary of the Interior consents to the bill in toto.

WRANGELL, ALASKA

NOTES ON THE COUNTRY ADJACENT.

Essentially a fishing town, the town of Wrangell derives but little from the mining industry. It is an outfitting point for some prospectors, but very little in the way of actual mining has ever been done in the district. Several groups of claims near-by are undergoing development. Wrangell, as the second oldest settlement in Alaska, was the supply centre for one of the oldest Northern mining districts, the Cassiar. The city was first a trading-post, established early in the 19th century by the Russian-American Fur Co.; then, with the development of the district a Hudson's Bay post was established. After the Cassiar strike in 1873, an American garrison was stationed there.

J. G. Galvin, formerly of Nome, has taken a bond on the Ground Hog properties, which are on the mainland 15 miles from Wrangell. The claims are owned by W. D. Grant, S. C. Shurick, Brigham Grant, and Donald Sinclair. The price for the six claims is stated to be \$50,000. Galvin plans to do some development work soon. But little more than surface work has been done so far. The properties are 3000 feet above sea-level. Test shipments three years ago showed 15 tons to average \$46.80 per ton, it is claimed.

News from the McDames Creek country of the Cassiar is that H. Godfrey and associates, who have bonded a number of placer claims there, are working with a crew of men.

The most promising mining news is the discovery of new silver-lead prospects on the Stikine river, in the Devils Elbow district. The prospects caused quite a flurry, all of the residents of Telegraph Creek stampeding down-river when the first news leaked out. S. I. Silverman, J. E. Chilberg, and others are interested in the properties, having taken a lease and option on some of the holdings of Dixon, Bodell, and associates. The claims are located at Glenora, 110 miles from Wrangell and 40 miles below Telegraph creek, on the British Columbia side of the boundary. The properties are on the east side of the Stikine. The main drawback to the rapid development of the district near Glenora is the difficulty of navigation and the consequent high cost of supplies. Assay-values of samples from the Glenora are said to vary from \$38 to \$298 per ton. A company, the A. B. C. Metals Co., has been organized to finance these prospects.

The Stikine Mining Co. also has a crew of men at work on a newly discovered vein in the same district.

The last boat to make the trip up the Stikine took a number of prospectors to the Glenora district. Sixteen claims were staked and recorded in the Wrangell district last year, according to the files of U. S. Recorder Thomas. A Crown grant has been obtained on a group of 14 claims on the Iskut river, a tributary to the Stikine, by P. C. McCormick, C. M. Coulter, Alex. Vreath, E. S. Busby, George M. Whitney, Bruno Greif, John Maloney, and F. E. Bronson. The claims show chalcopryite.

At the Surf Inlet mine of the Tonopah Belmont company on Princess Royal island, construction work is making good progress in connecting the mine with tidewater.

TORONTO, ONTARIO

PORCUPINE, KIRKLAND LAKE, SESEKINIKIA, AND COBALT NEWS.

A valuation of the McIntyre, McIntyre Extension, and Jupiter properties is being made by C. H. Poirier of the Vipond, and M. W. Summerhayes of the Porcupine Crown, to obtain a basis for the proposed merger of the companies.—The Newray is preparing to resume active development on a large scale and is letting contracts for 30,000 ft. of diamond-drilling.—The Dome Lake has cut a 20-ft. vein on the 300-ft. level, the gold-content of which when first opened was \$9 per ton. It has been developed for 50 ft., with considerable improvement in grade.—Exploration carried on at the Dome Extension, under the option given to the Dome Mines, has given encouraging results. A diamond-drill hole put down 300 ft. east of the Dome property has encountered 75 ft. of good ore.—At the West Dome the shaft is down 325 ft. in ore yielding high assays. A 51-ft. vein has also been cut by diamond-drilling at a depth of 330 feet.

Mining in the Kirkland Lake district is active. The Tough Oakes is shipping between \$80,000 and \$100,000 of gold per month from the treatment of about 125 tons daily, a considerable proportion of which consists of tailing from the old amalgamation mill. Rich ore is being extracted from the 400-ft. level of No. 6 vein. Twenty-six drills are in operation, but only one of the large compressors can be operated owing to lack of power. With the completion of the power transmission-line from Cobalt, which is expected early in November, the production of the Tough Oakes and other mines of the district will be largely increased.—Rich ore has been found on the 300-ft. level of the Lake Shore.—The Wright-Hargraves, adjoining the Tough Oakes, which has two veins on the surface showing free gold, is being opened.

The Malouf properties in the Seseकिनика district, comprising three claims that were under option to Buffalo interests last year, are to be developed. John Papassimakes, who has taken a prominent part in the development of Boston Creek, has purchased a half-interest, after sampling had yielded satisfactory results. Five veins have been uncovered carrying free gold or telluride.

The vein recently discovered at 700 ft. on the Crown Reserve is opening well, yielding good milling ore and considerable high-grade across a foot of vein-matter. Another vein, 6 in. wide; cuts across it at right angles.—A contact has been let by the People's Mining Co. for the sinking of the shaft from the present level at 318 ft. to the contact, the distance being estimated at 250 ft.—The Adanac has found native silver in the vein on the west winze at 315 ft. together with patches of high grade. The vein is 14 in. wide.—The Trethewey is again on the shipping list, and the Hudson Bay lately reopened will make a shipment shortly.—The Cobalt Gem Mining Co. is being wound-up.—The Quaker City, south of the Gifford, is being reopened. The shaft, which is down 200 ft., has been unwatered and will be sunk deeper.

Gold output of the Dome in June was \$179,000 from 36,700 tons of ore, an average of \$4.88 per ton. Costs were \$2.62 per ton.

At a depth of 900 ft., a diamond-drill from the 500-ft. level of the McIntyre passed through 22 ft. of \$36 ore. A station has been cut at 1000 feet.

During June the Nipissing's output from 112 tons of high and 6380 tons of low-grade ore was \$294,660.

In the issue of July 8 it was stated that the Porcupine Vipond profit in 1915 was \$193,919; this was the total expense, the profit being \$31,136.

As the outcome of several meetings held by miners at Cobalt, it appears most likely that arbitration will be sought before any strike is attempted. In fact, the local union has given notice that it will apply for a conciliation and investigation board and it has definitely gone on record to the effect that the men will not strike until such board has been refused.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

On the Government railroad the Alaskan Engineering Commission is employing 2500 men, who receive a total of \$150,000 per month. On June 24 Congress at Washington appropriated \$6,000,000 for continuing construction work on the line. On the same date at Anchorage a suit was started in the District Court, whereby J. E. and F. L. Ballaine seek to recover \$450,000 for alleged damages sustained through a suit brought against them by the Alaska Northern Railway Co., in which the latter corporation sought to recover the Seward town-site and thus placed a cloud upon the title of the property at a time when its value reached a high point. The case was thrashed out in the Federal Court, and after a lengthy and spectacular trial, resulted in Judge Brown rendering a decision which gave the Ballaines title to their town-site. Since then lot-values at Seward have taken a downward slump, and the Ballaines feel that their financial loss, as the result of this litigation, has been nearly \$500,000. While the suit to recover damages is against the Alaska Northern Railway Co., the Alaskan Engineering Commission, through the purchase of this road, has fallen heir to it, although in no way a party to the transaction which deprived the Ballaines of any of their rights. This case may defer the payment of \$650,000 to the Alaska Northern Railway Co., and postpone the sale of lots at Seward. The military appropriation bill for \$500,000 also passed Congress. This means many improved roads, and \$350,000 will be spent between Valdez and Fairbanks.

The steamer *Burlington* will sail from Seattle on July 25 with 3000 tons of rails and other steel for the Government railroad to be delivered at St. Michael, thence to be conveyed up the Yukon and Tanana rivers to Nenana. The liner *Victoria* will sail for St. Michael on the same day with supplies to be similarly shipped from St. Michael to Nenana.

Preparations are being made to ship additional equipment to Alaska for the Alaskan Engineering Commission from the stock of surplus and obsolete equipment left over from construction of the Panama Canal, two ship-loads of which have already been sent, according to the *Canal Record*, published at Balboa. Arrangements for transportation have not been made, and the local representatives of steamship lines have been asked to keep the matter in mind and advise the Canal authorities if any of their vessels calling at Balboa would be interested in the shipment. Arrangements are to be made with the Alaskan Engineering Commission. The equipment will probably be ready for shipment about the first of September and will consist of 7 narrow-gauge locomotives, two 75-ton steam-shovels, four standard locomotives of 5-ft. gauge, and 50 Lidgerwood flat-cars. The heaviest lifts among the knocked-down parts are the locomotive boilers, weighing 15 tons each, and the steam-shovel car-bodies, weighing 14 tons each. The total weight of the shipment will be approximately 3000 tons. The equipment is being crated at Balboa by the Mechanical Division. If the shipment is to be delivered at Cook inlet, Alaska, this season it will have to leave Balboa by October 1 in order to reach port before the close of navigation. Seward, the other port at which it may be delivered, is open all the year.

KNIK

(Special Correspondence).—A trip through the Willow Creek district, with a side trip to the mouth of Moose creek, where

a contractor is getting out coal for the Alaska Railroad Commission, revealed the following points.

The season has been an extremely backward one, and all operators have been greatly handicapped by the snow on the mountains and hard freighting conditions. This spring the Willow Creek Mines, which operates the Gold Bullion mine on the divide between Willow and Craigie creeks, has installed an additional 5 stamps in its plant making a total of 12 stamps. The new ones weigh 850 lb. each, but will be probably increased to 1050 lb. to conform with the rest of the equipment. A new pipe-line is also being laid that will supply water-power under a 400-ft. head.

L. S. Robe, superintendent of the Independence Gold Mines Co., is installing a 5½-ft. Denver mill at the property on Fishhook creek.

The Mable Milling, Mining & Power Co. is installing a small Denver mill at its property on Archangel creek. The mill, which is approximately 1200 ft. below the mine, will be connected by a 3500-ft. aerial tram, having only one tower between terminals.

R. G. Doherty, who has a contract to supply the Railroad Commission with 2000 tons of coal, has opened a small mine on the west bank of Moose creek, about 1½ miles above the right-of-way, and is grading for a track down the creek. A 255-ft. drift has been put in on a 5-ft. coal seam with a counter gangway 15 ft. above, from which the brasts will be turned off. The bed is 5 ft. thick, strikes south-west, and dips about 50° south-east. The coal is a lignite and rather dirty, but a fair product can be secured with careful hand-sorting. Both walls are sandstone.

Knik, June 21.

The Talkeetna Mining Co. recently filed articles of incorporation. It has a capital of \$1,000,000, with headquarters at Anchorage. The company owns four lode claims in the Knik district. F. B. Wiseman of Anchorage is the Alaska agent.

The Alaska Anthracite Railroad Co., with a capital of \$500,000, has been formed by Henry Hewitt, Jr., James Campbell, and Clark E. Davis. The company will construct a railroad from Controller bay to the Bering River coalfields.

ARIZONA

The State Tax Commission has valued the producing mines of Arizona at \$172,731,914, an increase of \$54,795,910 over that of the previous year. The Inspiration is \$19,000,000 and the United Verde Extension \$5,500,281 more. These are new producers. Other gains are \$5,000,000 by the Copper Queen, \$9,000,000 by the United Verde, \$5,000,000 by Ray Con., \$1,000,000 by Arizona Copper, and \$9,000,000 by Calumet & Arizona. The status of counties is as follows: Cochise \$67,807,915; Gila, \$41,738,692; Yavapai, \$26,166,763; Pinal, \$16,312,249; Greenlee, \$15,778,941; Mohave, \$3,128,987; Pima, \$1,161,539; Santa Cruz, \$215,826; and Yuma, \$119,762.

Owners of mines containing a mixture of vanadinite and wulfenite and crocoite have had considerable trouble marketing the same, owing to the inability to separate the vanadium and molybdenum content. Either was undesirable in the other. It is now possible to separate these minerals, and more money is being paid for low-grade ore than was formerly paid for clean high-grade concentrate. Moreover, gold and lead are also paid for, which was not done formerly. There are a great many deposits of such ores in Arizona, whose owners

have been unable to market them. If they will communicate with Charles F. Willis, director of the State Bureau of Mines, Tucson, they will be advised where such ores may be sold.

COCUINE COUNTY

The June output of Shattuck-Arizona was 1,446,080 lb. of copper, 61,889 lb. of lead, 24,636 oz. of silver, and 367 oz. of gold.

MARICOPA COUNTY

To develop 11 claims in the Cunningham Pass district, 8 miles north-east of Wenden, J. Burson of Phoenix, A. W. Snyder of Globe, and others have formed the Wenden Copper Co., with a capital of \$100,000. Some good copper-gold ore has been shipped. Pumping machinery is to be ordered.

MOHAVE COUNTY

The recent sale of Black Range shares to E. McNeal & Co. of Chicago amounted to \$100,000, payments to be at the rate of \$4000 monthly. A new 2-compartment shaft is to be sunk in place of the old incline opening. Some good ore was opened by this shaft. A 60-hp. Western hoist is in use. The mine is considered one of the promising properties of Oatman.

CALIFORNIA

AMADOR COUNTY

The Plymouth Consolidated reports as follows for June:

Ore crushed, tons	11,400
Value	\$56,685
Working expense	\$28,000
Development charge	\$ 7,321
Surplus	\$21,364
Other expenditure	\$15,525

GLENN COUNTY

According to news from Willows a gold-bearing lode has been unearthed by A. W. Roucroft between two deposits of manganese, along the road that connects the Alder Springs and San Hedrin roads.

SAN BERNARDINO COUNTY

A shipment of 30 tons of \$200 ore has been sent to Salt Lake City by the Goldstone Mining Co. of Goldstone, the new district. In the June issue of the *Mining and Oil Bulletin* of

SECTION OF GOLDSTONE DISTRICT, CALIFORNIA.

the Chamber of Mines and Oil of Los Angeles, this district is described by A. E. Rau. The general altitude is 3500 ft. The accompanying section shows the ore deposition.

NEVADA COUNTY

Machinery is arriving at the Columbia and Ocean Star mines near Ormonde, including a 200-hp. generator to supply power for both. A 20-stamp mill is to be built at the Ocean Star. E. C. Klinker is in charge.

PLACER COUNTY

The Adventure gold mine of R. L. Turner of Colfax, has

been bonded by Salt Lake City people, who are to erect a small concentrating mill. The property is in Shirt Tail canyon of the Iowa Hill district.

PLUMAS COUNTY

It is expected that the new 100-ton mill of the Walker company will be completed early in August, so will the aerial tram. Recent diamond-drilling shows 56 ft. of 12% copper ore. Reserves are estimated at 183,000 tons, averaging 7%. Concentrate will be hauled to the Western Pacific line at Portola, thence to Salt Lake City for smelting.

COLORADO

BOULDER COUNTY

The tungsten situation at Boulder is as follows, according to the *Daily Mining Record*: W. G. Blake, a Denver buyer for the Latrobe Steel Co. at Pittsburg, has just shipped 10 tons of high-grade concentrate to the company by express, in a sealed car. In spite of dullness in the tungsten market, not one of the numerous mill projects under construction throughout the Boulder district has been abandoned. The Rare Metals Co. at Rollinsville has its plant in operation, and is buying large quantities of low-grade ore at the mill. The Degge-Clark mill is practically completed, and will begin operations within the next two weeks. The Vasco plant at Stevens will also be in operation before August 1. J. Gillingham Hibbs of the Red Sign properties in Boulder canyon states that the 25-ton mill of his company will be ready for operation by August 1. Several small plants, including the Montgomery mill on the Lord Byron tract, and the Grimm mill at Duncan are now in operation. In spite of the present dullness in the tungsten market, a spirit of optimism as to the future prevails at most of the local mining offices. One of the large buyers who has been inactive for months has received definite instructions to begin purchasing within 10 days, and he expects the other buyers to follow his example.

LAKE COUNTY (LEADVILLE)

Water in the Wolfstone shaft last week was only 20 ft. above the 950-ft. level, or bottom.—Enlarging of the Penrose shaft-station for the new motor and pump is complete. Cleaning-out upper levels is under way.

The Valley adit in Prospect mountain has further opened the large body of low-grade oxidized iron ore, containing pockets of shipping ore.

Four new turncres are under construction at the Western Zinc Oxide Co.'s plant. Plenty of carbonate ore is available.

SAN JUAN COUNTY

Ore and concentrate shipments from the Silverton district in June totaled 118 cars.

IDAHO

OWYHEE COUNTY

In a report on the new Denning gold and silver district, 45 miles by way of Oreana from Murphy, terminus of a branch of the Oregon Short Line, the Rowland Corporations of Nampa say that the county is a vast basin of low sweeping foot-hills, hemmed in to the north by the Silver City range and the Jarbridge mountains to the south, the Owyhees to the east. Alternating formations seem to occur in rapid order, giving away, however, to a preponderance of feldspathic granite. In some portions diorite dikes have intruded the granite. Some prospects are good. Parties going into the district should provide themselves with food and blankets. There are only two small tents and one small cabin in the camp. The Duval ranch, two miles below, is the only likely place to obtain supplies of any kind.

SHOSHONE COUNTY (COEUR D'ALENE)

On July 25 the Success company of Nine-Mile pays 3c. per share, equal to \$15,000. The total for 1916 is \$345,000, and \$1,919,000 to date.

The National Copper Co. at Mullan has closed its mine and mill on account of the low value of the ore.

The Stewart company has increased its capital from \$1,250,000 to \$3,000,000, in order to acquire other properties. Two in Nevada and three in Idaho are being considered.

A rapid increase in mining activity is reported from the Pine Creek region. Developments in the Constitution and Douglas zinc mines continue to be extremely favorable. The Highland-Surprise mill is producing 25 tons of concentrate daily. The Nevada-Stewart, Big It, Big Eight, and Nabob all report promising results.

MICHIGAN

THE COPPER COUNTRY

Objection is being made to the tonnage tax on copper, which has been proposed by the Federal government on the ground that copper is a munition of war. Homer A. Guck argues that a tax on copper, once on the books at Washington, would be retained permanently, while the tax on other munitions would automatically cease when the war in Europe is over. This would mean a permanent addition to the cost of producing copper. It is reported that the bill has been drawn by a man who knows so little of copper mining that he presumed the smelters buy the ore from the mines and then make exorbitant profits from the sale of the metal to European countries at war. Furthermore the large consumption of copper for peaceful purposes at home has been overlooked.

The Calumet & Hecla reports as follows for May, in pounds:

Mines	May	5 months
Ahmeeek	2,070,551	9,180,272
Allouez	953,069	4,215,323
Calumet & Hecla	6,865,907	30,939,745
Centennial	231,879	1,052,778
Isle Royale	1,128,401	4,896,952
La Salle	123,592	563,238
Osceola	1,775,222	8,219,725
Superior	331,432	1,472,341
Tamarack	620,314	2,931,094
White Pine	446,607	1,888,024

MISSOURI

JOPLIN DISTRICT

Ore prices at Joplin last week were lower. According to local information operators are unable to determine whether the weakening in the market which has steadily taken place during the last month is indicative of a return to before-the-war schedules, or whether the present market fluctuations and general instability merely precede a heavy buying movement on the part of Eastern consumers, which will result in a rise in prices. There is scant reason to believe the first theory to be correct, indications being all in the direction of a strengthening of the market and increased consumption. Many local operators claim that the operation of their properties is impossible on less than \$70 ore, and that a further decrease of prices means the closing down of a number of mines. At present, but little effect has been noticed in the output, which was 5969 tons of blende, 32 tons of calamine, and 577 tons of lead, averaging \$70, \$44, \$73 per ton, respectively. The total value was \$464,025, making \$20,939,066 for the year to July 8.

A 350-ton mill is planned for the Dr. Carl Mining Co., P. Demerath, manager, south of Galena.—A 300-ton mill is being erected at the Mary C. mine at Prosperity.

MONTANA

MISSOULA COUNTY

(Special Correspondence.)—There is marked activity in mining in the Cataract district, and prospects of a successful year seem assured. The Crystal Copper Mining Co., with head offices at Boston, is operating its mine on Cataract creek, 8 miles by wagon-road north of Basin. The company has opened

a promising vein at the 200-ft. level, and is now driving an adit to intersect the lode at the 400-ft. level. This is expected to be done by August 1. The president, John A. Allen, and managing director, Walter H. Wood, expect shortly to examine the work.

The Uncle Sam group of claims operated by Butte capital, is shipping ore to the Helena smelter. The property is on Cataract creek, four miles from Basin.

The Sims and Klondike mines, P. J. Manning, manager, are employing a few men opening the old 1000-ft. adit, and intend driving a 280-ft. cross-cut to connect with the Klondike shaft. Work is progressing satisfactorily, and shipments will be made in the near future. The head office of the company is at Boulder, Montana.

The Ruby & Columbia Mines Co. of Boston, has recently acquired the Sunset claims, situated on the outskirts of the town of Basin. Mining operations here have been delayed by heavy snow-fall this winter, but with the arrival of M. A. House, the general manager of the company, from Boston, development undoubtedly will be greatly accelerated.

Basin, June 28.

SILVERBOW COUNTY (Butte)

During June, Butte & Superior treated 52,600 tons of ore, yielding 15,200,000 lb. of zinc and 310,000 oz. of silver, also 540 tons of lead concentrate. The recovery was 94%. On July 11 the B. & S. tailing-dam near Meaderville broke away, inundating the north end of the suburb.

East Butte's June output was 1,629,560 lb. of copper and 41,503 oz. silver, against 1,517,000 lb. in May.

For the Butte & Bacoan \$264,000 has been subscribed. After paying debts there will be \$180,000 for resumption of work. A steam or electric hoist is to be ordered.

In the first 3 months of 1916 the Tuolumne company made a profit of \$42,939, from 10,310 tons of ore shipped. Its operations continue at the Main Range and Colusa-Leonard Extension.

At the Butte & Zenith the shaft is down 830 ft. Thirty men are working. Cross-cutting will be started at 1000-ft. depth.

Unwatering of the Butte-Detroit has been done to a depth of 950 ft., and should be completed to the bottom this week. The shaft is in good condition.

It is probable that the Northern Pacific Railroad will construct a spur to the Tropic, Main Range, Colusa-Leonard, and Butte & London, about 6000 ft. in all.

Financial problems of the Butte-Duluth company are still complex, and the receiver is trying to get together all interests. Debts amount to \$875,000.

According to the assessment report for taxation, the North Butte Mining Co. during the 12 months ended June 1, showed the following results:

	1916	1915	1914
Ore mined, tons	195,275	262,615	463,437
Yield	\$ 5,106,252	\$2,583,071	\$5,929,372
Mining cost	2,079,431	1,163,963	1,831,839
Transportation	61,154	31,548	46,494
Treatment	1,733,274	923,536	1,784,152
Total cost	3,873,912	2,219,331	3,726,365
Net profit	\$ 1,229,339	\$363,739	\$1,291,006

The Anaconda Copper Mining Co.'s report showed the following:

	1916	1915	1914
Ore mined, tons	4,346,061	3,311,188	4,714,673
Gross proceeds	\$59,334,085	\$29,908,184	\$29,164,094
Mining cost	19,166,854	13,391,552	17,816,795
Cost of transportation	1,234,773	620,551	1,105,758
Cost of reduction	10,092,566	6,752,895	8,957,896
Cost of marketing	1,469,581	2,391,714	3,379,478
Total cost	31,959,204	23,157,715	30,859,426
Net proceeds	\$14,363,881	\$6,750,439	\$8,613,741

*Includes \$8,715,428 spent for improvements.

NEVADA

ESMERALDA COUNTY

In hitherto unprospected ground, 250 ft. from the Velvet shaft of the Jumbo Extension, and at a depth of 770 ft., \$10 to \$15 ore has been opened on the foot-wall side of the vein-matter. Also at 900 ft. a raise has cut good ore.

HUMBOLDT COUNTY

The north drift on the 1700-ft. level in the Seven Troughs Coalition is now yielding 8 in. of \$700 ore. Since first cut in the main winze, the north drift has opened this shoot for 25 ft., and an equal distance to the south, where although good quartz, is showing, the value is not as high. The new level

GOLD ORE IN THE SEVEN TROUGHS COALITION MINE.

is designated as the 1700 ft. A new direct-drive compressor of 395-cu. ft. capacity from the Chicago Pneumatic Tool Co., just received at the mine, will shortly be in place. This will practically double the air supply.

(Special Correspondence.)—A thorough sampling of the old Tascorora Mines' dumps is being made on behalf of an Eastern syndicate. The main dumps are from the old Grand Prize, Independence, and Navajo properties, and contain thousands of tons of ore averaging around \$5 per ton in gold and silver, mostly the latter metal. A crusher has been installed and shallow holes are being sunk in the dumps to facilitate general sampling. Arrangements have been made to work the mines on a broad scale.

The new mill at the Kennedy mine, near Kennedy, has been placed in commission. Mine developments have been proceeding for several weeks and a fair quantity of good ore is available for the plant. L. St. D. Rolance is general manager, and S. L. Berry is superintendent.

The lower shaft at the Wolverine copper mine, near Winnemucca, is down 100 ft. Work has been suspended pending installation of machinery to take care of water encountered. The upper shaft is down 50 ft. on an orebody 2 to 5 ft. wide, containing over 15% copper, with some gold and silver. M. Endregg is superintendent.

Suit has been filed against the Lincoln Hill Mining & Milling Co. of Rochester by the First National bank of Lovelock, to recover on a promissory note for \$917.35, with interest, \$250 costs, and attorney's fees.

The Hatch Leasing Co. is erecting a mill to treat ore from its lease on the Buckskin National mine, at National. Large quantities of gold ore of excellent grade are stated to be ready for extraction.

The rise of silver has instilled new life into the Golconda area. Several properties are shipping, and re-opening of many old mines is reported. From the Bull Con. Caroline two cars

of ore averaging 5 to 15% copper are shipped weekly. S. B. Kasper is managing owner.

Winnemucca, June 30.

LANDER COUNTY

Unwatering of the Glasgow & Western copper mine in Copper canyon, in the Battle Mountain district, has been started. Water-level is at 440 ft.; the shaft is 590 ft. deep. F. Sommer Schmidt is in charge.

LYON COUNTY

During June the Nevada-Douglas company shipped 22 cars of ore to Utah, worth \$51,040. In May the output was 16 tons (18 cars) netting \$2320 per car. Shipments in 5 months totaled 1951 tons, containing 479,990 lb. of copper, valued at \$87,561 net. Ore treated locally at the leaching plant is not included.

STOREY COUNTY

The Sutro tunnel at the Comstock is of great value to present operations in the Ophir, Mexican, Union, and other mines on the lode.

OKLAHOMA

OTTAWA COUNTY

The new Netta mill of the Eagle-Picher Lead Co. in the Cardin zinc-lead district is to have many improvements over other plants on similar ore. The crushing department for one-half includes one 18-in. breaker, one set of 42-in. and two sets of 36-in. rolls, two revolving screens and one 24-in. elevator, all with a capacity of 40 tons an hour. The jig equipment at the Netta consists of two 42 by 48 roughers of six cells each; one chat-rougher, 36 by 42, and one 7-cell cleaner. The chat-rougher will take the chats directly from the rougher-jigs, and is between them. The jigs are built high and there is a special arrangement for taking care of surplus water. The sludge-plant will occupy a good-sized building a short distance east of the mill, and will be unusually complete. It will house 22 Arbuthnot tables, which will be operated by a 50-hp. motor and will also have an Eccleson ball-mill, which already has been installed, and is in the middle of the sludge-room and about 8 ft. lower than the tables. This mill pulverizes the middling from the tables.

OREGON

The Oregon Bureau of Mines and Geology at Corvallis, has resumed publication of its monthly 'Mineral Resources of Oregon,' the last one being issued in December, 1914. The May number of 114 pages deals with some little-known scenic pleasure places in the Cascade range, by Ira A. Williams. The number is well illustrated, and contains a good deal of interest to mining men.

JACKSON COUNTY

On July 10 an election was held at Medford to decide whether the people approved of the Bullis contract for construction of a railway to the Blue Ledge mine. The voting was 1009 for and 366 against the proposal, a win for those in favor.

SOUTH DAKOTA

LAWRENCE COUNTY

At Lead on July 1 the first first-aid contest in the Black Hills was held. The seven teams were composed of Homestake employees, who worked hard to win the \$350 in prizes donated by the company.

The Ofer company in the Bald Mountain district is sending 100 tons of ore daily to the Mogul mill at Terry.

UTAH

BEAVER COUNTY

Renewed activity is reported from Fortuna.

At Newhouse the Utah Leasing Co., treating the Cactus tail-

ing dump by flotation, is to double its capacity to 800 tons daily. V. P. Strange is general manager.

In the Star district the Master Key company has been financed for development.

JUAR COUNTY (TINTIC)

On July 25 the Iron Blossom company pays 10c. per share, equal to \$100,000.

The Tintic Milling Co. has levied an assessment of 4c. per share, due August 4. With this the mill is to be increased from 100 to 300 tons daily.

SALT LAKE COUNTY

On August 10 the South Hecla company, shipping 50 tons of ore daily from the Cottonwoods, pays its initial dividend, of 15c. per share, or \$29,450.

The Cardiff company has 5 caterpillar-tractors and 60 trailers carrying ore from Big Cottonwood. The output is soon to be 300 tons daily.

SUMMIT COUNTY

Good progress is being made in erection of the new electrolytic zinc plant of the Judge Mining & Smelting Co., according to the general manager, George W. Lambourne to the Salt Lake Tribune. When the new plant is in operation it will produce 15 tons per day of the highest grade spelter. In doing this it will treat between 30 and 40 tons of high-grade zinc concentrate per day, supplied by the present mill. The concentrate will be put into solution and the metal will be deposited from the solution on aluminum cathodes, circular in form and revolving at a slow speed while immersed in the solution. The electric current will be employed to deposit the zinc in the form of sheets of spelter on the aluminum cathodes. The use of revolving cathodes is a departure from present methods, and is said to be a decided improvement. As far as is known it will be employed for the first time at the Judge plant. The spelter will be produced at a very low cost. The mine is at present shipping a small tonnage of zinc concentrate which is being stored until the new plant is in operation.

UTAH COUNTY

A deposit of manganese containing 50.39% metal, without impurities, has been opened on the Birch Springs ranch in Lucerne valley, near Manilla, by A. S. Brown and J. D. Wines.

WASHINGTON

STEVENS COUNTY

The Columbia Copper Co., capitalized at 1,000,000 shares at \$1 each, has been organized by Spokane men to take over and operate the holdings of the old Highgrade Mining Co. in the Deer Trail district. C. M. Carroll is president, Alex Robinson is vice-president and general manager, Oscar Olson is secretary-treasurer, and T. J. Vaughan Rhys is consulting engineer. The purchase price of the group is \$100,000, payments extending over a period of 10 years. This is a property on which large sums were expended years ago. A smelter costing \$114,000 was erected, but was never of any use. Some good machinery is available.

CANADA

BRITISH COLUMBIA

Some attention is being given by American mining men to the Erie gold-silver district, 30 miles from Nelson. Promising mines are the Arlington, Second Relief and Keystone. There are deposits of many minerals in different parts of the region, the metals appearing in combination as copper-gold, gold and silver, and lead-silver-zinc. All the natural facilities for mining operations are at hand. There is unlimited water-power that can be harnessed at small cost, and an abundance of timber for all purposes. Capital is necessary for exploitation.

Profits of the Standard Silver Lead company in May were \$38,436, a decrease on account of less ore shipments. Lead returned \$61,616, and zinc, \$18,260. The balance is \$59,373.

The Rambler Cariboo's June profit was \$11,000 from lead alone.

The Jackson Bell Zinc Mines Co. of Kaslo is being fully re-organized at Spokane by C. E. Caldwell and others. Shipments of 400 tons monthly are soon to be removed.

The Delta mine on Rocher De Boule mountain, near New Hazelton, has been purchased for \$50,000 by M. T. Watts and associates of Edmonton, Alberta, according to P. J. Jennings, president of the Spokane-Rocher De Boule Mining & Copper Co., who recently returned to Spokane from the district. The first payment is said to have been paid already to B. Thompson and B. Hallihan, the two prospectors who located the property recently. Work has been started on the 6000-ft. adit through Rocher De Boule mountain to open at depth the veins of the Rocher De Boule mine. In the upper workings ore now is being extracted at the rate of 100 to 130 tons daily, and regular shipments to the Tacoma smelter are being maintained. The ore averages 10% copper, and it is said that development and exploration have disclosed bodies that warrant the expense of driving the long adit.

YUKON

According to William Sime, territorial assayer at Whitehorse, there were 1242 samples received for assay, while 1573 assays or quantitative estimations were made. Of the former, 389 came from Whitehorse district, 197 from Dawson, 184 from Mayo, 156 from Wheaton, 50 from Conrad, and 12 from Atlin. Assays made included 1041 for gold and silver, 337 for copper, 102 for lead, 26 for platinum, and 23 for antimony, with several for zinc, tin, nickel, tungsten, and molybdenum. In the Whitehorse district considerable activity in copper mining is evident, four copper companies are to ship ore to the smelter, namely, the Pueblo, Grafton, Copper King, and War Eagle. Of these the Pueblo will be worked on the most extensive scale. This group was closed down shortly after the outbreak of war, but has lately been re-organized under a new company, and at present the shafts, which were allowed to fill with water, are being unwatered, and shipping of the ore will be started as soon as possible. It is the intention of the company to ship an average of about 300 tons of ore daily and employ from 200 to 300 men. The Grafton copper mine has been shipping ore steadily from July 1, 1915. During that period over 5000 tons has been sent to the smelter, averaging 7% copper and about \$3 in gold and silver.

In the Wheaton River district, outside parties have bonded six of the best antimony properties, and are getting ready to ship at least 100 tons of ore per month. This deposit is said to be extensive. On the Buffalo Hump group of gold and silver mines, in the same district, local parties have taken a two years' working bond on the ground, and will shortly commence operations preparatory to shipping.

In the Conrad district steps are also being taken to open some of the Windy Arm properties.

In the Dawson district, the Bear Creek Mining Co. intends working its quartz properties on a comparatively large scale this summer. The company intends to erect a modern 10-stamp mill, which is at present in Whitehorse waiting transportation. The company has also received rock-drills, air-compressors, electric motors, etc., which will be put to work as soon as possible. Considerable work has already been done on the property.

In the Mayo district, the Silver King mine has been hauling ore all winter to Mayo landing, for shipment outside.

The future for ore-mining in the Yukon territory has never looked brighter than at the present time, and particularly so for the southern end, where everything points to this being a banner year.

THE METAL MARKET

METAL PRICES

San Francisco, July 18.

Antimony, cents per pound	15
Electrolytic copper, cents per pound	28.50
Pig lead, cents per pound	7.00-7.75
Platinum: soft metal, per ounce	\$65
Platinum: hard metal, 10% iridium, per ounce	\$69
Quicksilver: per flask of 75 lb.	\$83
Spelter, cents per pound	12
Tin, cents per pound	40
Zinc-dust, cents per pound	20

ORE PRICES

San Francisco, July 18.

Antimony: 50% product, per unit (1% or 20 lb.)	\$1.00
Chromite: 40% and over, f.o.b. cars California, per ton	13.00-14.00
Manganese: 50% product, f.o.b. cars California, ton	12.00-20.00
Magnetite: crude, per ton	7.00-9.00
Molybdenum: 50% and over, per pound	0.60-1.15
Tungsten: 60% WO ₃ , per unit	25.00-35.00

EASTERN METAL MARKET

(By wire from New York.)

July 18.—Copper is dull and easy; lead is also dull and weak, spelter consumers are now interested.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date	Average week ending
July 12	61.87
" 13	62.87
" 14	62.62
" 15	61.87
" 16 Sunday	62.87

The market has been somewhat erratic, but not weak. A continuance of present buying in London may advance rates a little, but in the absence of this support the present level seems high enough for the time being. Exports from London to India total \$185,000 to June 28, against \$2,652,000 in this period of 1915, a decrease of 16,000,000 oz. It is considered that the Indian Bazaars are not inclined to take a favorable view of the future, being influenced by reports of Indian government purchases. The Indian market is generally sensitive and swayed by rumor. Chinese sales created an unsettled feeling there. London transactions in 5 months were as follows, in ounces:

	1916	1915
Imports of refined silver	37,502,989	39,275,610
Exports of refined silver	20,563,249	32,518,165

COPPER

Prices of electrolytic in New York, in cents per pound.

Tin is easy at 38.25 cents.

Shares of the Aluminum Co. of America recently sold at \$40 each; a year ago they were \$25 to \$30. Additional capital costing over \$75,000,000, to more so the annual output, from 200,000,000 lb., are nearly complete.

Eastern Metal Market

New York, July 12.

For many months the 'wise ones' have been preaching that the metal market would suffer a reaction. The reaction is here or impending, yet despite the predictions, nearly everyone appears to be shocked at the dullness which has overtaken the market and at the resulting declines in prices. Perhaps the only influence that could check the present trend of copper, zinc, lead, and antimony would be renewed war buying; but none is in sight. It should be remembered, however, that the metal industry is not going to smash by any means, and that prices can decline several points yet, and still be productive of handsome profits. In fact, with an expansion of domestic demand, conditions will be far healthier than they have been, even at lower prices. Everywhere there is a shortage of labor which restrains expansion, but this may be remedied now that the munitions' makers are finishing their contracts, and in most cases not getting new ones.

Copper is inactive and lower.

Zinc is dull and lower, but enquiry from galvanizers is a good symptom.

Lead is lower and dull, although a flurry of buying followed a cut of $\frac{1}{2}$ ¢. The independents are taking what business there is.

The heavy June deliveries are held responsible for a dull market in tin.

Antimony is lower, but consumers show no interest.

Aluminum is a trifle lower.

The iron and steel market generally is quiet, except for export business. Russia has just purchased 365,000 tons of rails, delivery to be completed by July 1917. France and Great Britain also want rails. Russia also purchased 165,000 tons of barb wire, while the Allies are seeking 100,000 tons. Europe is also buying steel-making pig-iron.

COPPER

The market is lifeless, and the nominal prices are lower. Practically the only quotations obtainable are those of offerings made by second-hands or brokers, and it is questionable how much copper could be obtained from these sources. It is suspected that some of the metal offered is being supplied by the smaller producers, in which event perhaps more can be obtained than appears on the surface. The more important producers are well sold up until September, as repeatedly said before, and this is the one sustaining influence. Electrolytic can be had today at close to 25.50¢, cash, New York, and Lake at about 25.75¢, prompt delivery in each case. Consumers have been out of the market for about three months, and there is no indication of any resumption of buying. Sheet copper is quoted at 37.50¢, but it probably could be had $\frac{1}{2}$ ¢ lower. Brass rods are quoted at 38 to 39¢, and sheet brass at the same level. New business in these products is lagging, but the mills have plenty to do in filling existing contracts. Offers made to British buyers at these prices have brought the response that the proffers are "ridiculous." Electrolytic copper at London is down to £128. Exports, July 1 to 11, totaled 4913 tons.

ZINC

Quotations have continued to decline, and buyers have steered clear of the market so far as buying is concerned. Yesterday, however, there was a good volume of enquiry from galvanizers, which at least shows interest on their part. So far no buying has resulted. The brass mills show no inclination to buy. Spot zinc was quoted yesterday at 9¢, New York, and 8.75¢ St. Louis. August was quoted at 8.25¢, St. Louis, and September at 8¢. It is doubtful whether producers are anxious for any extensive business at present levels, most

of them looking for a turn upward in the near future. They are known to be averse to selling round lots for future delivery. The London quotation has been declining, though the downward movement there appears to have come to a halt. The quotation yesterday was £44 for spot. Several reasons are mentioned to account for the present state of the market, among them the lack of domestic and export demand, large stocks, and over-production. Some interest has been aroused by offerings of Japanese spelter in this market, but the quantities so far mentioned are not sufficient to have much influence. A firm of Japanese exporters and importers has offered lots of 50 tons. Exports to the 12th totaled 2124 tons. Sheet zinc has been reduced to 15¢, carload lots, f.o.b. smelter, 8% off for cash. Reports from the West are to the effect that the production of zinc ore is being curtailed.

LEAD

Late on Wednesday, July 5, the A. S. & R. Co., reduced its quotation $\frac{1}{2}$ ¢, or to 6.50¢ per lb., New York, a reduction of \$10 per ton. It is assumed that the company was not getting its share of what little business was doing, and that it did not wish to "hold the umbrella" for the independents any longer. The move did little good, so far as the company was concerned, for the independents at once cut the new price, \$1 and \$2 per ton. Following the cut there was a flurry of business, but it only lasted about one day, and then the market again became quiet. The leading interest yesterday quoted 6.50¢, New York, and 6.42 $\frac{1}{2}$ ¢, St. Louis, while the outsiders asked 6.45¢, New York, and 6.25¢, St. Louis. Lead is the most active of the metals, but as one of the trade says, "this is not saying much." Spot lead at London is quoted at £28. Exports in 12 days totaled 1037 tons.

TIN

The heavy deliveries of June have evidently put a quietus on business for some time to come. In the week ended July 8 only 250 tons was dealt in, and this week the market has been dull to stagnation. Spot Straits was quoted yesterday at 38.50¢, while Banca could be had at 37.75¢. The markets at London and the Straits Settlements are weak, London being quoted at £169 15s. for spot Straits yesterday. Futures are easy. Arrivals this month so far total 725 tons, and there is afloat 2234 tons. Not much is coming to light as to the consumption of the electrolytic tin made by the A. S. & R. Co. at Perth Amboy, New Jersey, but its use is presumed to be satisfactory in view of the company's own tests.

ANTIMONY

In a dead market, spot Chinese and Japanese can be had at 15.50¢, and metal in bond can be contracted for at 12¢. In the latter, a little business has been done. Needle antimony finds no market at 10¢ per lb. It is understood that certain interests which recently engaged in the manufacture of antimony cannot profitably operate their plants with the metal under 30¢ per lb. That money has been lost in antimony is frequently heard.

ALUMINUM

No. 1 virgin aluminum, 98 to 99% pure, is lower at 59 to 61¢.

ORES

Antimony: There is no market, and no quotations are obtainable, nominal or otherwise.

Tungsten: The enquiry for tungsten ore and ferro-tungsten is extremely light. Holders of the former consider that they should receive \$30 to \$35 per unit, while the consumers are not inclined to pay much over \$20. Makers of ferro-tungsten find less demand from the makers of high-speed steel, and are beginning to look rather anxiously for orders.

COMPANY REPORTS

ESPERANZA, LIMITED

This company controls operations of the Esperanza Mining Co., whose property is at El Oro, Mexico. The report of the manager, Charles Hoyle, covers the year 1915, and includes the following general remarks as to operating conditions in Mexico:

Transportation service was badly disarranged during the fall of 1914, and supplies could not be brought up to the mine from El Paso, Texas, nor Vera Cruz, Mexico. There was a slight improvement in view during the last half of December, which was, however, not forthcoming and was completely dissipated on January 26, 1915, when due to a change in political affairs at Mexico City, all rail service was discontinued and El Oro was cut off completely from the outside world. Supplies were carefully stored at Vera Cruz and El Paso, where they were kept in safety until they could be moved. The stock of most of the supplies was gradually exhausted at the mine until there was no cyanide, candles, carbide, electric lamps, nor necessary chemicals for use in the assay-office. A special permit was obtained from one of the higher officials of the Government, and during February and March a carload of supplies was brought down to Irapuato, thence to Celaya and Acambaro, and 30 cases of cyanide were brought over to the mine. During the spring of 1915, rarely was there any communication between El Oro and Mexico City by rail, and at no time was there any freight service available. Travel by the so-called passenger trains was anything but pleasant, and one has but to experience a trip on top of a crowded box-car in the hot sun or rain for a few hours to appreciate the comforts of the situation. The only consolation one had, was that he was not packed inside with his more unfortunate brethren. Letters and newspapers were unheard of for many months at a time. Much of the time watchmen had no illumination at night, and electric-lamp globes became so scarce as to cause serious apprehension; more so, because all foreigners and native employees were entirely unarmed, not even being allowed to have a pocket weapon. The work at the Sirio mine suffered much delay because of the lack of transportation facilities, since the necessary equipment, such as hoist, transformers, motors, compressor, and pumps, could not be sent out from Esperanza. The absolute lack of transportation continued until about November 1, when the newly-recognized Government began to offer a limited service to the public; and during November and December advantage was taken of the opportunity offered, and many necessary supplies from the United States, Mexico City, and Vera Cruz were brought to the mine. El Oro became the centre of revolutionary activity from February until October of the year under review. During the last few days of February the place was, it may be said, completely abandoned, due to the situation, only a few representatives of the mining companies remaining, with the necessary pumpmen to keep the mines from 'drowning.' About this time (March 4), a fire broke out in the town at night, and had it not been for the prompt action on the part of the mining companies, a large part would undoubtedly have been destroyed. At one time fighting took place close to the Esperanza mill, and the 3000 and 440-volt transmission-lines were shot-down and tanks were perforated by bullets. During the changes in control of the El Oro during these months the district was entirely unprotected, and looting and stealing were perpetrated on the defenceless inhabitants by bandits; and it was during just such a situation that about 30 men, armed with rifles, pistols, and machetes, raided the Esperanza property at night, cut their way into the vault in the zinc-room and stole what bullion they could get. One man was killed and two others seriously wounded in the affair. It should be stated that

proper action was immediately taken by those representing the interests of Esperanza in this country, and the matter is being well taken care of, the present Government aiding as much as present conditions will permit. A food shortage naturally obtained on account of the lack of communication, and Esperanza paid its employees in food-stuffs which were brought in overland. At one time 20% of the payroll was being given in the prime necessities of life. When it was seen that operations would be delayed indefinitely, the staff was cut down to the minimum consistent with proper care of the property. Operations, although on a limited scale, were delayed by the lack of sufficient power at times, due to the interrupted service of the power company supplying the current, brought on by the abnormal conditions prevailing. During September, no electric power was available for a period of 14 days at one time. Since only limited transportation was available at this time, sufficient wood for the steam-plants could not be brought to the mine. During the last months of the year labor unrest became apparent and two strikes were declared at El Oro, which, however, were later settled. Special messengers were sent through the various lines whenever opportunity offered, with mail and cables. It is pleasing to state that the mail and telegraph service is again practically normal (February, 1916). It hardly seems necessary to remark on the loyalty displayed by the staff during the unpleasant and critical conditions experienced during the year under review; actions speak louder than words.

Mine development covered 4592 ft., of which 1953 ft. was on the Descubridora vein, and 1788 ft. on the San Rafael vein. Work on the former was encouraging, but the vein is narrow (18 in.) and erratic in value. Results on the San Rafael were discouraging at depth. Some of the ore contains lead and zinc. Two 4-ton Jeffrey electric locos were purchased for use on No. 5 and 7 levels. Diamond-drilling amounted to 938 ft. Ore reserves are estimated at 156,000 metric tons, which should yield \$520,000 profit under normal conditions. There is also 40,000 tons of low-grade slope-filling, and 200,000 tons of tailing, the latter worth \$150,000 net.

The mill treated 25,005 tons, work being suspended on February 25, 1915. The bullion was worth \$143,486, and profit \$57,304. In 1914 and 1915 the total revenue was \$1,186,025, of which \$315,000 was paid in dividends. The balance is \$168,132.

Production to date is 172,344.998 (Mexican) from 2,085,936 tons of ore.

CORDOBA COPPER CO.

This company operates in Spain in charge of James Hocking for the general managers, John Taylor & Sons. During 1915 the average monthly development was 609 ft. Results were disappointing at 1550 ft. in the San Rafael section. The eastern shaft was sunk to 1529 ft. Reserves are estimated at 134,289 tons, containing 2.64% copper. The amount of ore opened did not equal that extracted, namely, 89,639 tons. The position improved later in the year. There was also raised 1,389,227 tons of water, an average of 3806 per day. The pump averaged 5.92 strokes per minute. The rainfall was 39.73 in. Baling raised another 220,449 tons.

The concentration plant treated 48,585 tons of 1.74% ore from dumps. Some ore was hand picked. The Murex plant treated 11,970 tons of middling and slime assaying 1.42%, yielding 1136 tons of 9.45% concentrate. The recovery was 67.67%. Combined with the wet mill the extraction was 79.7. This increased to 73.3% later in the year. The sintering and briquetting plants, together with crude ore, supplied the smelter with 19,184 tons of material. The converters smelted 1767 tons of blister copper.

The revenue was \$630,000, and profit \$14,000. The net balance of \$5000 was carried forward to 1916.

Gold output of the Rand in June was 761,000 oz. and 4,628,000 oz. for the half-year.

INDUSTRIAL NOTES

Information supplied by the manufacturers

The Seattle office of the LIDGERWOOD MFG. Co. has been moved from 807-809 Western Avenue to 63-65 Columbia Street.

The CYANIDE PLANT SUPPLY Co. writes that the War makes it necessary for it to have offices in Victoria street, Westminster, London, so they are now at No. 28 on that street.

Electric hoists of half and one-ton capacity, type S-1, are discussed and illustrated in Bulletin 48,906 of the SPRAGUE ELECTRIC WORKS of the GENERAL ELECTRIC Co. Complete dimensions are given of the various sizes.

In its pamphlet No. 28-B the COLORADO IRON WORKS Co. of Denver describes its Portland continuous revolving-drum type vacuum-filter. Use of the machine for dewatering flotation concentrate, and filtering and washing cyanide slime is illustrated. A list of users is given.

The AMERICAN MANGANESE STEEL Co. of Chicago announces the purchase of the Brylson Steel Casting Co.'s plant at New Castle, Delaware. This modern foundry has a monthly capacity of 400 tons of steel, and will be making manganese steel by July 15.

The Black Prince Tungsten mill, near Boulder, Colorado, was recently completed and put in operation by the DENVER QUARTZ MILL & CRUSHER Co., for John T. Duncan. It is to have an additional unit supplied by this firm, for delivery by July 15. When in operation the capacity of the mill will be 75 tons per day.

The GENERAL NAVAL STORES Co. of New York announces that it will hereafter carry stocks of G. N. S. flotation oils at Denver, and will be in a position to fill orders from that point within the next 30 days, following June 21. John D. Davis, with office at 1550 Glenarm street, Denver is the Colorado representative.

The latest folder, No. 64, of the CHAIN BELT Co. of Milwaukee, gives information on its traveling water-screens. These screens are designed primarily to remove refuse and foreign material from water before it enters power-plants, steel mills, or any other industrial plant requiring large quantities of clean water.

The Sprague Electric Works of the GENERAL ELECTRIC Co. has issued bulletins 48,706, 48,907, and 49,600. The first deals with motors and controllers for flat-bed and small rotary printing-presses; the second with 500-lb. electric-hoists for shop use; and the third covers flexible-steel armored conductors, steel conduit, fittings, and tools.

The latest bulletin of the HENDRIE & BOLTHOFF MFG. & SUPPLY Co. of Denver describes and illustrates the Leadville drill-column hoist. Five pages discuss the 'super-Leadville' hoist, model 5, which is designed for loads up to 1200 lb., against 700 lb. by the regular sized machine. A 4½-hp. air engine is used. The drum holds 1080 ft. of ½-in. rope. Total weight is 360 lb. net.

In a circular entitled 'Flotation,' the UNITED NAVAL STORES Co. of New York, states that wood-cresote leads in quantities used, compared with the other oils or tars, excepting petroleum oil. Pine-oil was originally at the head of the list, but while it became scarce, and high in price, the wood-cresote was found to give results just as good in most instances. Eventually wood-tar will probably replace most of the wood cresotes, and other oils in flotation, because it contains about 50% of the wood-cresote in a crude form, besides light oils; because its cost is less than one-half of the wood-cresote; and because there is more of it produced than all the other wood-products combined. This is backed also by the fact that a number of mining concerns are now using it in considerable quantities.

EDITORIAL

T. A. RICKARD, Editor

WAR exports have not ceased by any means. In three days \$31,757,418 worth of such material went out of New York. This included \$5,501,903 of copper ingots and \$12,593,319 of explosives.

SURFACE TENSION is a term used with such wearisome iteration in writings on flotation that it seems worth while to agree upon an abbreviation. 'S.T.' is disagreeable, so we suggest 'sur. ten.' Eventually, we may write it 'surten,' for convenience.

PAPER is expensive, because so much of it is wasted. The Government bureaus issue tons of printed paper much of which is just so much good pulp squandered in the effort to make a showing before Congress. We have just received the Monthly Review of the U. S. Bureau of Labor Statistics. We wonder who reads it.

UNDoubtedly trade in War supplies has diverted interest from the effort to open new lines of trade with South America and Asia. We heard a lot about opportunities in those directions during the early stages of the War, but not much lately, except the excellent propaganda of the National City Bank of New York. That has done a great deal of useful work.

REFERRING to the article on the financial chaos in Mexico appearing in our issue of July 15, we can add now that an official decree imposes the death penalty on a Mexican and deportation on a foreigner that refuses to accept the Carranza *infalsificable* currency at its enforced value, of 20 centavos or 10 cents gold per peso. Incidentally this currency bears upon it no statement of any obligation to pay.

ALASKA is prospering. Recent reviews of mining lay stress on the growth of copper production, now contributed by 15 enterprises, chiefly in the region tributary to Cordova and near the railway being built to Fairbanks. Mining for gold is lively, especially around Juneau, where big developments are in progress. We are glad therefore to announce that Mr. Emil E. Hurja, who made a tour through Alaska and the Yukon in our behalf last year, is now re-visiting the mining districts of the North, or more accurately North-West, and will contribute a series of articles describing the principal operations. In this issue we give the first of the series, an article on the Ketchikan district.

GOLD mining in Western Australia, and elsewhere under the flag of the great belligerents, is suffering from the imposts necessitated by the expenses of warfare. At Kalgoorlie, for example, the mining companies have

not only to pay more for all their supplies and equipment, by reason of abnormal freight rates and scarcity of skilled labor, but they have to face the Federal land tax, the Federal income-tax, and the State profit tax. Under the last of these an attempt was made to treat the cost of development as 'profit,' but a favorable verdict in a test case has side-tracked this absurdity, pending appeal to a higher court. It is bad enough to treat dividends as income if paid by a mine that has not yet redeemed its capital expenditure. A mine is a wasting asset and the dividends paid by it do not represent 'profit' until its purchase price and equipment have been amortized. People forget this because they keep an eye on the shares, not the mine.

BLACK-LISTING of firms in this country by order of the British government will affect sundry metal-producing enterprises and it has aroused the interest of many engaged in mining. One local firm that does a big business in oil with Australia is on the list. This presumably is a part of the economic warfare that is to follow present hostilities in Europe. It is none of our business what the belligerents do to each other and we do not doubt that the Entente agreement to restrict the commerce of the Central powers is in response to the Zollverein that the latter have organized among themselves. Nor do we question the right, or even the advisability, of a belligerent discriminating against those that aid his enemy, but we do question the wisdom of publishing a black-list and thereby martyring a number of persons or corporations and arousing a reasonable irritation. This, we take it, is the first gun in an international trade war, to be waged with greater intensity as soon as military operations cease. It may be ungracious to comment on this policy, but we doubt either the success or the continuance of it for long. Great Britain, naturally, will abandon free-trade and protect herself, as she ought to have done long ago, against the syndication, cartels, dumping, and bounty systems that prevailed at her expense in central Europe, but neither Great Britain, France, nor Russia can start a general black-listing of firms in neutral countries without introducing a kind of medieval reprisals that will do as much harm to them as to their enemies. We expect a modification of sentiment on the question when the intense acerbities of the War become alleviated by time.

USEFUL service has been rendered to mining by the American Mining Congress, but its entry into journalism is probably the least useful of its services to the industry. The July publication contains some startling announcements suggestive of the misinformation com-

mon in the daily papers. One head-line announces "Lake Superior iron mines shipping ore at rate of 2,000,000 tons monthly." This is a statement that will surprise anyone who knows anything about Lake Superior, for it would indicate an annual shipment of 24,000,000 tons, when as a matter of fact, the 1916 shipment is estimated at 60,000,000 tons or $2\frac{1}{2}$ times the amount stated. The editor of the Mining Congress Journal appears to have divided the 10,000,000 tons shipped during the first five months of the year by five, forgetting that shipping does not open on the lakes until the middle of April. Another thriller says "Nevada's copper output is double that of last year." This would mean that the Nevada Consolidated, instead of producing 62,726,651 pounds, as in 1915, is producing at the rate of 125,000,000 pounds per annum. That is not what has happened. It is the value of the output that has been nearly doubled, thanks to the combined effect of better prices and a 50% increase in tonnage.

BOLIVIAN tin was discussed comprehensively by Mr. Howland Bancroft in our issue of last week. As noted by him, the mining and milling methods in use on the Andean plateau are crude and unscientific. The importance of tin to the industries of the United States is not generally recognized. During the past five years the value of the tin imported into this country has averaged \$45,000,000 per annum. This compares with the value of this country's output of primary spelter in 1914 of \$36,011,000 and of primary lead during the same year of \$42,286,000. In other words, the normal production of zinc or lead in this country has been of less value than the tin imported. A ton of tin is worth in ordinary times nearly ten tons of lead or zinc. This country uses 55,000 tons of tin per year, about 1000 tons per week. The new tin smelter of the American Smelting & Refining Co., at Perth Amboy, will produce only 100 tons of metal per week, 10% of the American consumption, when it attains to full capacity. Tin mining and smelting should offer an attractive field to American enterprise and we would like to see the establishment of a tin smelter on this coast, with a view to supplying the regional requirements in tin-plate,terne-plate, and alloys.

RIO TINTO is the largest copper mine in Europe. The mine is in the province of Huelva, in southwestern Spain, and the company owns the railway to the port of Huelva. During 1915 the dividend paid was 55%, compared with 35% in the preceding year. The net profit was \$6,189,005, against \$3,588,155 in 1914. Income is obtained both from sale of metal and pyrite. In 1913, a normal year, the copper produced at the mines was 21,062 long tons, while 635,900 tons of pyrite was sold, besides 825,408 tons of washed and other sulphide ores, for the manufacture of acid. A total of 1,859,571 tons of 2.19% ore was mined, practically all by open-cut methods, the metal produced amounting to 36,320 tons, which was more than the output of the Calumet & Hecla or any of the American disseminated copper mines dur-

ing that year, except the Utah Copper. The Rio Tinto mines are owned by an English company that acquired them in 1872 at a cost of approximately \$19,466,000. The French have a large holding of shares. About 10,000 men are employed, and four villages are included in the nine square miles of property. The mines have been worked successfully by the Iberians, Phoenicians, Carthaginians, Romans, and British.

FLOTATION is to the fore in this issue, two articles being devoted to the subject. Mr. Joel H. Hildebrand, Assistant Professor of Chemistry in the University of California, discusses and illuminates underlying principles from the point of view of the physicist. Undoubtedly we want more of this kind of scientific study, for the actual use of the process in the mill cannot be intelligent, and is unlikely to be progressive, unless it is based on a clear understanding of the physical phenomena underlying the rationale of this metallurgical method. We believe that Dr. Hildebrand's contribution will help many of our readers to a better conception of elementary principles. Next we reproduce a bulletin just issued by the U. S. Bureau of Mines, embodying a study of flotation as applied to oxidized ores. Messrs. O. C. Ralston and Glen L. Allen, of the Salt Lake City branch of the Bureau, need no introduction to our readers. The subject they discuss is of the most timely interest. Several months ago we announced that Mr. Joseph T. Terry, Jr., had found a way of treating oxidized copper ores. His method, like those described by Messrs. Ralston and Allen, depends upon sulphidizing the carbonates, forming a film of sulphide that aids flotation. Similar tests on lead-carbonate ores show that sodium sulphide is the best agent for the purpose, and it is now being adopted at Pioche. The results are encouraging and promise to enlarge the field of usefulness, already wide, of the flotation process.

ATTENTION has been drawn to the unpreparedness of this country in regard to many things by the disturbance of normal trade relations during the European war. The stimulus that this discovery of weakness is giving to the chemical industry in particular will have far-reaching results. The man with a process for extracting potash from feldspar no longer is regarded as a crank; indeed it has come to be expected that the potash chemist will take a place in the industrial ranks of the day as a matter of course. The Cushman and Coggeshall process for making the chloride has established the fact that from American feldspar a product may be made equal to that formerly imported from Europe. Another simple method is that known as the Hart process, based upon the fusion of feldspar with sodium sulphate and carbon, extraction with sulphuric acid, and precipitation of the potash as an alum. This is an attractive field for the chemist possessed with that sort of imagination which is dubbed inventive genius. Mr. Chester D. Gilbert of the Smithsonian Institution has recently sent out a call for efforts to discover some more economical and practicable means of oxidizing ammonia obtained

in by-product coking so as to make cheaper nitric acid. At the present time the production of ammonia sulphate in the coking of coals in this country is about 225,000 tons per annum. With the plants now under construction this quantity will be double in the next twelve months. The possible output is above 700,000 tons. In other words, the fixed nitrogen represented by 475,000 tons of ammonium sulphate is yearly being wasted because in that form no adequate market exists. Here is a great opportunity for chemical ingenuity. Not only is nitric acid needed for the manufacture of fertilizers, but as a military necessity it is one of the urgent affairs connected with that preparedness which an awakened people will insist upon, no matter who may have the shaping of our political destinies during the next four years. The Government is giving considerable attention to the possibilities of utilizing our unemployed water-power in the fixation of nitrogen in the form of calcium cyanamid, but the waste from our crude methods of coking is one of the sad facts of industry that should stimulate chemists to remove this blot from an epoch that boasts of conservation and progress.

The Mexican Muddle

We publish a timely letter from Mr. E. A. H. Tays, a mining engineer recently resident in Sinaloa, who corroborates and amplifies the description of Mexican financial conditions as given by our regular correspondent in the issue of July 15. Mr. Tays writes, as many mining men would, in a spirit of goodwill toward the unhappy country in which he has lived and worked from choice. That makes his complaint all the more convincing. To him and to the scores of other engineers and operators driven out of Mexico owing to the withdrawal of protection by their own government, we proffer our understanding sympathy. Their disappointment and disgust is natural. Dispossessed of their property and driven from their work, they may be pardoned for even more irritation than they express. Meanwhile the pitiful farce continues to unfold like an endless cinema-film, punctuated with scenes of lurid brutality. The latest proposal, that of an international commission of eminent American and Mexican citizens, seems to us only "the passing of the buck" to the next man, a mere shifting of responsibility and a postponement of action. The trouble with Mexico is that it has no effective government, the administration at Washington having recognized a group of predatory politicians as a *de facto* government. Under the anarchy that results from political chaos, our own territory has been invaded by bands of marauders, whom the Mexican rulers are unable to suppress and whom our soldiers are forbidden further to pursue under threat of war with Mexico. Villa is again in command of large forces and is making faces at both administrations, that of Señor Carranza and that of Mr. Wilson. We have to maintain a large force of citizen soldiers along the border to protect ourselves from the inhabitants of a country

whose government we recognized prematurely as responsible and capable of maintaining order. Disorder reigns supreme. Six weeks is likely to be wasted in further parleys between the members of the Commission while famine drives more of the unhappy peons into Villa's mob of looters and desperadoes. To join one of the so-called armies in Mexico is now the best way to get something to eat. No kind of settlement of the Mexican question is possible until Mexico has a real government, able to represent the Mexican people in negotiations for the adjustment of grievances and able to redress the calamitous condition of the country. 'Watchful waiting' at Washington, 'wait and see' at London, and *mañana* at Mexico City are all expressions of political incapacity.

On July 31 Señor Carranza decreed the nullification of all civil records made during "the usurpation administrations" of his predecessors. This is to be mitigated by re-validation on appeal to the authorities now in control, thereby opening unlimited probabilities of graft. Until the end of the current year is the time set for such re-validation. This action, we understand, was prompted by Señor Luis Cabrera, who with General Alvaro Obregon constitutes the power behind the tinsel throne of the First Chief. That gentleman has placated native sentiment by issuing insulting statements for domestic consumption while sending polite notes to Washington, but this double play will prove ineffective unless Villa and his followers are crushed. These, of course, hope to unsaddle Señor Carranza from his unsteady seat by appealing to anti-foreign sentiment and they will succeed unless the *de facto* Government is more cordially supported by the other military adventurers of the Constitutional party than is apparent. The Mexican problem persists and no make-believe will solve it. We believe that conditions will have to be worse before they are better and that the logic of events will prove too strong for any commission of enquiry, like the Niagara conference, which left no mark on current history, only a memorandum of conversations.

Publicity in Mining

When the Engineering Congress was in session in San Francisco, last year, a usually well-informed engineer made the remark that he supposed mining along the Mother Lode was dead, as he had heard nothing about it recently. We assured him that the region to which he referred so casually was in a state of remarkable prosperity and that to it largely California owed her first place among the States of the Union as a producer of gold. The articles that have appeared since then in this paper will have told that engineer, in New York, a good deal concerning one of the principal gold-mining regions of North America. But how came it that he should have labored under such a misapprehension? The answer is that the mining companies operating on the Mother Lode consist for the larger part of privy, technicalities and syndicates, most of which desire no publicity, and some even endeavor to escape it. Is this wise? We have ours

cussed the matter with several of the principal operators, men of wide experience and high character, and from them have elicited the reasons why they are content to work their mines without attracting public notice. What applies to them and their operations will apply to others elsewhere to whom publicity is repugnant. In the first place, they argue that any advertisement of their profits tends to invite the attack of the labor agitator and even the less arrogant claims of the labor-union, because a show of large production and successful results gives ground for a demand that wages be raised and so forth. In the same category we may place the idea that a statement of production and profit gives the tax-collector an excuse for raising his impost. To this we would reply that mystery always exaggerates, that a mine operated secretly is the sport of fanciful stories, that the actual profit made by a mine is nearly always less than that reported in the adjoining community, for example, in the hotels and saloons of adjacent towns. If the assessor wants to get at the facts, he is empowered by law to obtain them; and if the labor agitator is anxious to ascertain how much money a mining company is making, he can do so by enquiring among the men working on the mine, obtaining from them usually a highly-colored version of the figures in the case. In short, we believe that secrecy does not protect; on the contrary, it renders a mining company particularly vulnerable to injury from such sources. Next, we are informed that the small company, working its own mine in its own way, has no stock to sell and no share quotations to boost. That is well. We recognize that the kind of mining done by such proprietaries, on the Mother Lode and elsewhere, represents a clean operation; it aims to extract gold to the profit of the proprietors and not to victimize the public by selling shares at an inflated price. So far, so good. But the State of California, the city of San Francisco, and the county in which the mining is being done are each and all entitled to be considered in the matter, and as good citizens, these modest operators should consider them. It is to the advantage of the State, county, and city that honorable and successful work of this kind should be made known, so that our domestic mining industry may receive public support. Gold mining is a business that is not hurt by competition. We cannot see how a disclosure of facts creditable to all concerned is going to do any harm to anybody. We do not insist that the mines be listed on the local stock-exchange, but we venture to point out that a holding in a privately-owned property is not a liquid asset. If any member of a small syndicate or private company owning a mining enterprise that courts seclusion should wish to sell his interest, as is frequently the case in any business, he has no market outside the members of his group, because nobody knows anything about the mine outside that group. A property is enhanced in value by becoming a liquid asset. We hope to be pardoned for discussing the matter frankly. Far be it from us to teach our grandmother the pneumatic extraction of the aluminous contents of an egg. However, we hope our friends on the Mother Lode

will consider the matter seriously. A great deal of new and promising work is being done along the foot-hills of Amador, Calaveras, and Tuolumne counties at the present time. Old mines are being re-opened, many of the deepest mines are doing handsomely, and there is every reason, it seems to us, why the world at large should be informed concerning the excellent work in progress.

Copper, Zinc, and Lead

In 1913, before the War created abnormal conditions, the world's production of copper, zinc, and lead was respectively 1,002,284 metric tons, 999,890 metric tons, and 1,142,264 metric tons. In round numbers the production of each of the three metals was a million tons. In 1900, the total output of copper, zinc, and lead was respectively 491,435 metric tons, 479,128 metric tons, and 849,168 metric tons. Thus, 16 years ago the production of copper and zinc was half what it is now, while that of lead was only a quarter less. From 1900 to 1913, the average price of copper varied between 12 and 20 cents per pound, that of zinc between 5 and 7, and that of lead between 4 and 6 cents. Obviously, if the conditions of mining and smelting these three metals were such that they could be produced at the same cost, and the amount of each metal required by the world remained as shown above, then the price of each would be the same, disregarding the possible effect of monopolies and selling agreements. However, if the price of these base metals became equal, the demand would cease to be equal, because copper would be preferred for purposes for which zinc and lead are at present used and for which copper is now too expensive. Copper has more valuable properties than either zinc or lead, being tougher, more ductile, a better conductor of electricity, and more attractive in appearance. Again, the higher value of the metal enables the miner to exploit deposits of copper that are much lower in grade than the equivalent deposits of zinc or lead. The copper of Michigan comes from ores that average 1% in copper; the production of many of the other great copper mines of the world, including the disseminated chalcocite deposits of the Western States, the Braden and Chuquibamata in Chile, and the Rio Tinto in Spain, is derived from ores of about 2% grade, varying from 1.5 to 3%. Ores of zinc and lead, on the other hand, are plentiful in much higher ratios. The Butte & Superior mine in Montana, which is now contributing 12% of the American production of zinc, is mining ore containing 16% zinc. The mines of Broken Hill, in Australia, yield ore containing 12% zinc and 14% lead, with about 10 ounces of silver per ton. The Consolidated Interstate-Callahan mine in Idaho has ore running from 20 to 30% zinc. The Bunker Hill & Sullivan lead-silver mines, also in the Coeur d'Alene, produced 37,292 tons of lead in 1915 from ore averaging 8% lead. It is true that in south-east Missouri the companies mining disseminated ore successfully treat material of 3% lead, but conditions there are exceptionally favorable to a low cost of exploitation.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Conditions in Mexico

The Editor:

Sir—It is a pity that editorials like 'The Mexican Fizzle,' and articles like 'Conditions in Mexico,' to be found in your issue of July 15, could not be read by the President and his advisers. I should like to add to what your correspondent has said.

No Mexican dares to criticize, publicly, public acts, but we have been reared to believe no public servant can be exempt from criticism unless his public life is exemplary. The President, the General, the Governor, in Mexico, is not a public servant; he is an over-lord. What is power for, if not to be used? For the public weal? Well, hardly, unless the public weal coincides with personal aims. However, my remarks are in no way meant as derogatory to Mexico or its people. It must be understood by the American people that the present Government does not represent Mexico or its people; and, also, that most of the Mexican people are friendly to the American people, and there is no country in the world where a decent law-abiding foreigner is shown more respect and courtesy. It should also be understood by the Mexican people that the Mexican people themselves are Mexico's greatest enemy and not the U. S. Government. Mexico is now in the hands of the very worst elements in the country, with a very few exceptions. Señor Carranza himself is an educated and wealthy man, but he belongs to the old school, and whatever he may believe to the contrary, having had no training in democracy, and having been raised in the old vice-regal atmosphere, his idea of government can be only domination. He has even changed an article of the Mexican Constitution (Art. 5, if I am not mistaken) by decree, and that too, at a time when he was nothing but the head of a warring faction, and could have none of the powers with which he thought himself invested. Before this, although fighting for Constitutional rights, he tried to depose the constitutionally elected governor of Sinaloa, who had given him material aid at a time when it was vital to Carranza. And he would have deposed the governor had not he met determined opposition from General Carrazo. I mention this only to show what the First Chief is. He is surrounded by some able men, but most of the officers of his army are ignorant and dishonest, many being unable to read or write, and only a very few having more than a sixth-grade education. I refer to this merely to sustain my statement that the country is now in the hands of the very worst elements in Mexico, and to show the futility of expecting a gov-

ernment of any character while such factors are in control. They do not represent the Mexican people.

During the last two years the Mexican people have been robbed and murdered and every vestige of rights ignored, and the foreigner has fared the same. The best people—the educated and the wealthy—have been driven out of the country. And now the American government has forced all Americans out of Mexico instead of demanding that our rights as foreign citizens be respected, enforcing the demands if not heeded. The course adopted by the Administration is bringing about, not intervention, but just what neither country desires, war. The bulk of the middle class is tired and sick of the present muddle, and the great peon class is apathetic. But all are cowed, and, for a number of reasons not necessary to discuss, bow the head. I said to a young fellow who was criticizing conditions: "There surely is one way to alter them." "What! I bear arms?" he asked excitedly and in a deprecatory way. "Yes, my friend, either that or you will bear the burden."

I have digressed from my original intention of adding a little light to the monetary situation in order to give some light on the inner conditions that are less known, so that the whole may be better understood. Right here let me repeat: The Mexican people have no enmity for the law-abiding decent foreigner. Whatever men's motives, they can only be judged by their public acts, and the present financial muddle in Mexico certainly reflects no credit on the Government. Your correspondent would lay the chief blame on Señor Cabrera. But such is not just, for the decrees are signed by V. Carranza, and the blame must be laid wholly on his government. When the first fiat money was issued, it was forced into circulation at par with the peso, and a peso is, legally, one ounce of silver 902.7 fine. Although the people at large were not enthusiastic in the reception given the new paper money (and it was very crude at first) still, as it was issued under penalty of fine and imprisonment and was really the lesser of two evils—the other being forced loans—it went into general circulation at par and remained so for some time. The early bills, issued in good faith, all had an expressed obligation on the face of them. The State or the Army Corps, or the Constitutionalist Army "will pay the bearer one peso." These were counterfeited, of course, but it is publicly believed by the Mexican people that the statement by your correspondent that the Government issued two forms of the same bill and called one counterfeit after it was once in circulation, is a fact. It is hardly to be believed that

anyone would copy a bill exactly and then put on the signatures one-half or double the size of the original, as in the case of the Monclova issue. I commented on this with a member of Señor Carranza's cabinet, and he, of course, refuted the charge. "But," I told him, "I have seen the brand new bills of the so-called counterfeits put directly into circulation by the troops." To this he replied that they had notice that some of the Army paymasters had bought up counterfeit issues (at a low price, of course) and had issued them to the troops, keeping the legitimate issue. He also said that they could do nothing toward punishing such acts at that time. When these bona-fide issues were retired later by decree, without being redeemed, they were replaced by the Vera Cruz issues of the Constitutional government, afterward called the *rescaldados*. Instead of bearing a promise to pay, the legend read: "Will pay this bill." The animus is evident at that date. These bills, the Government said again and again, over the signature of Señor Carranza, would be respected and would never be repudiated. Your correspondent shows how they were thrown out of circulation, being replaced by a new, so-called *infalsificable* bill, which the Mexican public believes meant (and I am only voicing what I have heard many Mexicans say) that the Government would only make one issue and respect it. But this issue, the best made and a handsome bill, bears no obligation on it at all. On the reverse side it has this note: "This bill will circulate in accord with the decree of July 21, 1915," a year before this issue was put into circulation.

This would have been acceptable had it replaced the old issues at par and been exchanged for the five hundred million pesos acknowledged to have been issued by the Government. A like amount of the new bills was printed. But the various decrees, one following the other rapidly, forced the old issues out of circulation by June 30, and any one holding them after that date became liable to fine and imprisonment, and the bills would be void. The decree ordered all bills to be turned into the Treasury offices with a triplicate list, having on them a complete description of each bill, a job much easier ordered than complied with. But the new *infalsificable* was put into circulation *per se*, to be exchanged for the old at 1:1. This itself, although rated at, let us say, one peso, was valued by the Government at 20 centavos Mexican gold (10 cents U. S. currency) for redemption purposes. This 20 cents was offered for four pesos of the old bills that had been issued at par, and par value received for them in Mexico; or, in other words, the old would be redeemed at 5 centavos on the peso, and with a bill that had less behind it than the old—no more surely. A neat way of honestly reducing the national obligation 95%! What it did do was to produce consternation and absolute bankruptcy and alienate 95% of the sympathy of the people from the Government.

To the above we can now add that a decree has fixed the death penalty for all natives who refuse to take the *infalsificable* bills at the Government rate, 10 cents U. S. gold per peso, and the foreigner refusing them will have

Art. 33 of the Constitution applied to him, which means, deportation as an undesirable alien.

All taxes, however, are payable in Mexican gold; and, in the case of mining, have been doubled. But, as one could not raise one thousand dollars of Mexican coin in any State, under penalty of death for failure, as practically no Mexican gold has ever been in circulation at any time, it simply reduces down to all taxes having to be paid in U. S. currency. But you are fined if you dare offer anything for sale in exchange for U. S. gold. I can cite two cases, within my personal knowledge, of persons that were fined.

In October last, I believe, a bill of the *Ejército Constitucionalista*, called the *aguila negra*, was decreed out of circulation as counterfeit, notwithstanding the fact that much had been put in direct circulation by the Army itself. Last April (1916) this same bill was decreed into circulation again, at least on the West Coast, but went out again with all the rest. These are facts, not dreams nor vagaries. What need has any Government of Mexico for such tricks? Say 500,000,000 pesos (\$250,000,000 U. S. gold) has been issued, and even if half has been squandered or stolen, it remains a sacred obligation on the present Administration, for the portion used honestly put that administration in power and should be honestly accepted. What is \$250,000,000 in gold as a debt for a country like Mexico if decently governed? In two years of peace and honest government, not a sign of the present distress would be apparent, and only the debt would remain; but, if honestly borne by all, it would fall lightly on all and be onerous on none. The people at large, the workers, pay it anyway. It will certainly not be paid by Señor Carranza or any or all of his collaborators. Then why try to wipe out the obligation in such a way that it falls so heavily on the holders of the bills as to induce absolute bankruptcy and loss of national honor and consequent loss of credit? It certainly needs no special financial ability to readily see the sure way out of the difficulty. With its natural resources, the little State of Sinaloa alone, 100 miles wide by 400 miles long, can support 25,000,000 people, and alone could assume all of the Mexican national debt of 1,000,000,000 pesos, or \$500,000,000 gold. Of course, if the Mexican nation at large puts up with such dealings by the clique in power (150,000 at the outside, out of a population of 15,000,000) outsiders have nothing to say. That we must concede, even if the Mexican population is too supine to submit. But, when the foreigner goes to Mexico under treaty rights and is shuffled out of most of a life-time's earnings in the manner described (to state the case mildly), has he to submit, has he no right to state his case and demand remuneration for honest loss? Has his government no obligation to enforce an honest settlement in case the Mexican government should ignore his rights, as the present government is ignoring the rights of its own citizens? Mexicans may have to stand for it. Do we?

E. A. H. TAYLOR.

Berkeley, California, July 20.

Mining in Arizona

By Charles F. Willis

THE mines and smelters of Arizona have been working at so high a pressure in 1916 that they are making record productions all round. If they continue at the present rate, they will make an output of 600,000,000 lb. of copper, against 432,467,690 in 1915, according to reports received by the U. S. Geological Survey from Victor C. Heikes of the Salt Lake office. A corresponding increase in the output of the precious metals, and a gain in that of lead and zinc at the greatly increased prices, will make the total value of the metallic output in 1916 nearly double that of 1915, which was about \$88,000,000. Arizona not only retains first place as a copper producer, but is yielding at a rate nearly twice that of any other State. Aside from the unusually active market, several factors have aided this increase, such as the settlement of the strike at the Clifton-Morenci mines in January. The International smelter, which treats ore from the Inspiration mine, contributes the greatest part of the increase, for this plant is supplying one-quarter of the State's total output of copper. Increases and improvements were also made at the United Verde, Miami, Calumet & Arizona, and Old Dominion mines; and the Saseo smelter in Pima county was again blown-in. The railroad to Ajo was completed and work begun on the 4000-ton leaching plant.

Tungsten has furnished excitement, but the total aggregate production is small compared with copper. Oatman has had a real boom, but gold plays a relatively small part in the total value of the State's metals.

It is proposed in the revenue bill before Congress to place a tax upon copper smelting, singling out copper from all the other metals. Yet the copper stocks of Arizona have not been characteristic 'war babies.' The Inspiration mine, which is increasing the copper production of the State over 25%, is in no way a product of the great contest across the Atlantic. The New Cornelia at Ajo, which will add 32,000,000 lb. of copper to the annual production, likewise was planned long before the War.

It is true, of course, that practically all of the larger mines have increased their production, owing to the high prices, but they are disturbed in their plans for immediate expansion by a notification from Eastern refineries that they have received more copper bars than they are able to handle at present. In consequence, the Copper Queen is restricting its output to about 15,000,000 lb. per month. At the Calumet & Arizona smelter the same condition is understood to apply, the refiners having notified the management of the congestion now existing, which has caused them to stack copper bullion instead of immediately refining it. The output there was

approximately 7,600,000 lb. per month. The Kansas City Structural Steel Co. is erecting derricks at the C. & A. for handling the steel for the new roaster addition, the acid-plant, enlargement of the power-house, and machine-shop. The foundation for the acid-plant was completed several weeks ago, and much of the steel has arrived.

Since the end of the miners' strike, the Shannon Copper Co. has shown a steady increase in production. In

WILSON AND METCALI IN LINES OF ARIZONA COPPER CO. AT METCALI

May the output was 1,071,000 lb. of copper, an increase of nearly 100,000 lb. over April. The cost of production at the Shannon is higher than that of any other Arizonan company. Apparently it costs about 18 cents to turn out a pound of copper, but the average May selling price was 28.625c, and the total earnings for the month were a trifle under \$100,000. During the first five months of 1916 the Shannon earned \$220,000 net. This amounts to about \$1 for each share of outstanding stock, and advices from the East are that the stock

holders are expecting a dividend soon. There is no necessity for accumulating a greater surplus, for the company had a working capital of more than \$750,000 on June 1. Of this sum, however, \$190,000 is set aside for the retirement of the Shannon-Arizona railway bonds.

The production at the Old Dominion smelter for the month of June was slightly in excess of 3,000,000 lb. In addition to the copper produced at the Old Dominion smelter, there was over 750,000 lb. produced from Old Dominion and United Globe concentrates at the International smelter. The Old Dominion smelter is at present taking a considerable tonnage of custom ores from the outlying portions of the district, as well as from the United Verde Extension mine at Jerome. Shipments are also being made from several of the old dumps on the company's property that show a profit at present copper prices by sorting thoroughly. Four furnaces are being operated. At the smelter power-house the converter-engine is being installed on its new foundation and should be running by the middle of July. Foundations are in place at the boiler-plant for two additional Stirling boilers. At the concentrator 800 tons is being treated daily, while the flotation-plant is treating about 300 tons of ore per day.

Several minor improvements are being made in the mill, including the installation of Senn vanners and cone-classifiers. A Marathon mill is also being erected to experiment with fine grinding. Two additional concrete concentrate-tanks are being built outside of the concentrator, and a slime-pond for settling slime is being constructed on the old Hamm lands.

In the mine department of the Old Dominion, 1200 tons is being hoisted daily. Most of this comes from the 12th, 14th, and 16th levels. A little stoping is being done in the upper levels for cleaning-up what remains of old orebodies. Development on the 10th level is being advanced near the Grey shaft to open the Old Dominion vein at that point. A drift on the 14th level is being pushed east of the Grey shaft to prospect the vein between the Grey and the Arizona Commercial-Copper Hill shaft. On the 18th level at A shaft, work has been resumed in the foot-wall drift, and it is expected that this drift will be connected and ready for operating within the next few months. The station on the 18th level at the A shaft is also practically finished. Development is proceeding west on the 17th and 18th levels from the west winze, where the conditions look favorable. Steps are being taken to concrete the pump-winze, which was recently holed from the 18th level to surface. Later the electric cables and steam and water lines will be moved from A shaft and installed in this pump-winze.

The Inspiration mine is producing about 10,500,000 lb. of copper per month, substantially in excess of the original estimate of 120,000,000 lb. per year. It is estimated that the company will earn during the current year sufficient to pay for all its mining claims, a total of \$18,000,000. Work on the erection of the additional concentrator sections will soon be under way, and they should be at work in the early part of winter. The mine

appears to be in excellent shape for the delivery of the added tonnage. Recently a record hoisting performance was established, when the mine produced 19,700 tons in 24 hours. This amount of ore is more than the 20 mill-sections would ordinarily handle, but at the rate of present increase it is conceivable that the mine might have to maintain a daily production of 19,000 tons.

Considerable attention is being given to the question of water reclamation for the mill-supply of the Inspiration, the arrangement of the tailing-dams being convenient for the purpose. It requires a good deal less power to pump water from the tailing-dams to the head of the mill than is required in pumping water from the wells in the flat below the smelter. Consequently the company makes every effort to return all available water instead of letting it run to waste. In order to clarify the water that is being returned from the lower dams, preparations are being made with the view to excavating a large canal-like opening in the surface of the material stored behind the Ellison canyon dam, which has now reached the limit of its tailing capacity. This canal, which will probably be made by means of a suction-dredge, will be used as an immense settling-tank that will allow the water to overflow in almost clear condition.

The New Cornelia is pushing construction work rapidly and Ajo is developing into a real city. Two distinct types of dwellings are noticeable, temporary tent-houses, and those being constructed of stone, brick, and cement, for permanence. Streets are being graded, houses, stores and offices erected, and parks decorated; the grass is growing, and the temporary nature of the town is gradually disappearing.

The United Verde Copper Co. has in progress the sinking of an interior three-compartment shaft from the 1000-ft. level, where the main adit, with standard-gauge tracks, connects with the underground workings, and through which the ore is hauled to the smelter at Clarkdale. The planned collar of the new shaft is close to the adit, and it is to sink to 2200 ft. The equipment ordered includes an Allis-Chalmers hoist, with Westinghouse electrical equipment. It is a geared double-drum hoist, driven by an electric-motor set, adapted to receive alternating current, and to furnish direct current to the hoist-motor and controlling apparatus. The hoist will have a speed of 1900 ft. per minute, and will operate to a depth of 3000 ft. The sheaves will be placed at the 800-ft. level, and the ore will be dumped by automatic dumping-cradles between the 800 and 900-ft. levels, then conveyed through chutes to storage-bins on the 1000-ft. level, a 1500-ton storage-bin on each side of the adit being equipped with loading devices. These plans were developed under the direction of Will L. Clark, general manager, and R. E. Tally, superintendent.

Plans to use steam-shovels in stripping the surface orebodies at the United Verde in the vicinity of the old smelter site are under consideration. These plans involve the removal of 80 to 100 ft. of overburden, making it practicable to mine the ores from the surface down, instead of by underground operations adjacent to the fire area.

The capacity of the Miami mill will be increased to permit a monthly yield of 5,000,000 lb. of copper. This increase, however, is not expected to become effective until early in 1917. It will involve new equipment and power-plant, work on which has already been started. There has been put into operation a 100-ton experimental mill for Miami's low-grade ore from which an extraction of about 80% has been made. With an output of 4,600,000 lb. in May, the Miami established a new high record. The cost approximated 8.7c. per lb.,

on the east and north. It is not known whom the engineers represent in this particular instance or what the examination signifies. The Ajo Consolidated is one of the oldest properties in the South-west. According to reports, more than 15,000,000 tons of ore is blocked-out. The ore is said to average about 2% as compared with 1.4% at the New Cornelia, and besides this, there are some patches of rich ore.

The Big Jim at Oatman has started something new, a visitor's day, set-aside by the management to permit people to see things for themselves; they are allowed to sample the mine anywhere they wish, and form their own conclusions. Mining men in the camp are made welcome, and the invitation also includes brokers, promoters, assayers, newspaper representatives, and the public in general. Many have taken advantage of the invitation.

It was with an entirely new staff that the Tom Reed mine, also at Oatman, started operations for June, when the new administration took the place of the officials whose retirement was announced recently. The following are the officers: pres., W. P. Moerdyke; vice-pres., Chas. Mushrush; superintendent, E. M. Rabb; consulting geologist, Ellis Mallery; resident agent, J. C. McCabe; master mechanic, J. W. Hayes; mine-foreman, A. C. Hoffman; engineer, Victor A. Light. Mr. Moerdyke announces a program of economy and efficiency in all departments. A complete examination will be made of the reserves and physical condition of the mine. Mr. Moerdyke states that the career of the Tom Reed is all before it, past performances being slight in comparison to the future. Yet from an extraction of slightly more than \$6,000,000 from the Ben Harrison claims, dividends aggregating \$3,000,000 have gone to the shareholders. In the past, information has not been obtainable from the company officials, but it is admitted that the Black Eagle shaft, beyond the Telluride and Combination, has 600 ft. in ore on the 565-ft. level. This is claimed to be merely the apex of the ore shoot, and it is hoped that it may prove as great a deposit as the United Eastern, though not as yet developed to the same extent. It exceeds the Ben Harrison itself and is now known to be the biggest orebody in the mine. The average for the entire known portion is said to be \$20 per ton.

THE TIN produced annually by the world can be taken in round numbers at 100,000 tons worth \$1000 per ton, or a total of \$100,000,000. Though it is not generally appreciated, this is worth as much as the world's normal output of zinc and lead, each of which at 1,000,000 tons per annum, worth approximately \$100 per ton, is also valued at \$100,000,000.

LEAD produced by the Bunker Hill & Sullivan Co. during 1915 was 74,584,711 lb., which is approximately equal to the output in copper of the Calumet & Hecla Co. The lead was sold for 4 7/8c. per lb., while the copper brought 18.11c., or nearly four times as much.

MAP SHOWING JEROME AND CLARKDALE.

against a January cost of over 9c. Miami's normal monthly production may now be regarded as approximately 4,500,000 lb. copper. Estimating the June yield at this figure, the output for the first half of 1916 is about 25,300,000 lb., produced at an average cost of slightly less than 9c. per lb. On the basis of 4,500,000 lb. per month, the yield for the concluding half-year should approximate 27,000,000 lb., or close to 53,000,000 lb. for the year.

Calumet & Arizona engineers, some of them the same that sampled the New Cornelia, are sampling the Ajo Consolidated property, which adjoins the New Cornelia

An Extra-Lateral Problem

By Robert M. Searls

A recent decision of the Supreme Court of Montana throws light on a new complication in the law of extra-lateral rights as applied to veins joining on the dip. The questions decided are an extension of those principles outlined in the *Ajax-Hilkey* case (31 Colorado, 131, 72 Pacific 447) and the *Del Monte-Last Chance* case (171 United States, 55), but disagree in part with the ruling in the *Stemwinder* cases. They will be best understood by reference to the following diagrams, which are copied from the decision as reported in 156 Pacific, 409.

FIG 1

FIG 2

The plaintiff in this case owned the Badger State and Emily claims, the defendant owned the Pilot claim. The two lodes shown on the diagram apexed in both the Badger and Emily claims but united on the dip at the point *K* and thereafter continued as one lode underneath the Pilot claim. The order of seniority of location was (1) Badger, (2) Emily and (3) Pilot. The southerly of the two veins shown was the discovery vein for both the Badger and Emily claims. Suit was brought by the owner of the Badger and Emily claims to enjoin extraction by the Pilot owner of ore lying beneath the Pilot claim and within the limits of the extra-lateral plane of the Badger-Emily lodes. The question raised on appeal was as to the boundaries of the plane to which the plaintiff might lawfully claim title and hence obtain an injunction.

The trial court awarded an injunction prohibiting the Pilot owners from mining upon the portion of the vein

beneath the Pilot claim bounded by planes drawn through the Emily west end-line and the Badger States east end-line projected north indefinitely. From this decision the defendant appealed, claiming that the plaintiffs had no right to that portion of the plane lying within the Pilot boundaries and bounded by the lines *BF* and *BC* (Fig. 1). In this contention they were sustained by the appellate tribunal on the original appeal, but on rehearing the injunction was modified so as to exclude as not belonging to the plaintiff only that portion of the plane lying below the junction *K* and bounded by the lines *KT* and *KC* (Fig. 2).

The line of reasoning adopted by the Supreme Court in its final decision on rehearing was, briefly stated, as follows: (1) If two veins unite on the dip, the owner of the senior vein takes that portion of the lode below the union (Revised Statutes Sec. 2336); (2) therefore his ownership below that point should be governed by the boundary planes of the senior vein in the absence of any other consideration; (3) if the reasoning stopped here, the south or Badger vein, being the discovery vein for both claims would be bounded extra-laterally by planes passed through *BC* and the Badger State east end-line as to the Badger claim, and by *BF* and *DE* as to the Emily claim, leaving the shaded portion in Fig. 1 not subject to ownership by the plaintiffs; (4) but the north or Emily vein is a secondary vein, apexing within the Emily claim, and the owners of the Emily are entitled to an extra-lateral right thereon measured by the length of free apex of such vein lying between the end-lines of the Emily claim (*Ajax Mining Co. v. Hilkey*, 31 Colorado, 131, 72 Pacific, 447), that is, it is bounded by planes passed through *ED* and *AC*; (5) this right however will be limited below *K*, the junction of the Emily and Badger veins, which is inside the Emily vertical boundaries, by the boundaries of the senior Badger right wherever it conflicts; (6) but as demonstrated in proposition (3) the Badger right of itself does not include the shaded portion of Fig. 1; (7) It follows that the secondary Emily vein has an extra-lateral right *BFJL* (Fig. 2), which is independent of the Badger right and is found by subtracting the Badger right from what would be the Emily extra-lateral if the Badger did not exist, (*Lindley on Mines*, Sec. 594, p. 1394); (8) therefore the plaintiffs, who are entitled to an extra-lateral right on both the Badger and Emily veins, should be awarded an injunction against the Pilot owners preventing the latter from working any part of the extra-lateral segment except the portion comprised within the shaded portion of Fig. 2.

It should be noted that in fixing the eastern boundary of the extra-lateral right to the north or secondary vein at *AC* instead of *BF* the Court departed from the rule of the *Stemwinder* cases but is in accord with the doctrine of the courts as laid down in *State ex. rel. Anaconda C. M. Co. v. District Court* (25 Montana, 504, 65 Pacific 1020) and in the *Del Monte* case (171 U. S. 55). In other words, within the boundaries of the end-line planes of the claim, the secondary vein is given an extra-lateral right based upon its length of free apex

and is not limited by the boundary planes of the discovery vein.

The accident of union of the two veins became important only because the right to the united vein below the point of union was the subject of inquiry. The north vein, having no extra-lateral as against the senior south vein wherever there would be a conflict in extra-lateral rights below that point of union, no right as against third parties could be asserted by the north vein owner at such conflict unless the senior right could prevail, even though ownership of the junior apex would have established the right if the conflict had not existed. A right cannot be predicated upon a trespass.

The case is a curious one in that, from the standpoint of the Emily owners the less apex they had on their discovery vein, the better it was for them. If the veins had crossed both end-lines they would have lost their right altogether because the end-lines were not parallel and diverged in the direction of dip. Had the discovery vein been more nearly coincident with the south side-line and hence shorter, the excluded triangle *JKC*, would have been still smaller and they could have claimed a larger segment under their secondary vein extra-lateral. It is an example of the complications into which the law governing extra-lateral rights sometimes leads.

Lead Salts, Alkalinity, and Solvent Power of Cyanide for Gold

By H. R. Edmonds

*In the course of experimental work on leaching roasted gold ore, special attention was given (a) to solutions foul with soluble sulphides, and (b) to solutions in which the sulphur was mainly converted into thio-cyanates and thio-sulphates, and none was present as sulphide.

The appearance of soluble sulphides in working cyanide solutions is of unusual occurrence, and was, fortunately, only a temporary incident, soon obviated by providing facilities for quicker draining and thus increasing the leaching rate of vats, but the thio-cyanates and thio-sulphates were always present in quantity varying with the sweetness of the roast. As the treatment of roasted ore by leaching is somewhat unusual, it may be as well to state that satisfactory extractions are being obtained, the main desiderata being rapid leaching, and either double treatment, or turning over the ore in the vats, that is, digging down into the sand as far as possible to allow of its exposure to the air.

SOLUBLE SULPHIDES. The general impression seems to be that if these ever occur, they are extremely unstable, and disappear on decanting from one vessel to another, if they are not already precipitated by the zinc always present in working cyanide solutions. A series of tests showed that their proneness to oxidation has been greatly exaggerated, that the presence or absence of protective alkalinity has little effect on their oxidation, but that soluble carbonates have a tendency to hasten oxidation. A much more effective oxidation of soluble sulphides takes place in the leaching vats; these after thorough draining have a strong oxidizing tendency on solution subsequently passed through—partly due to the air present in the drained vats, but probably largely assisted by the presence of ferric oxide in the ore. The use of ferric oxide in freeing town gas from H_2S is well known. Treatment with lead acetate was, of course,

quite effective in precipitating all soluble sulphides, but it remained to be seen what effect such treatment would have on the solvent power of the solution for gold.

EFFECT OF LEAD SALTS IN CYANIDE TREATMENT. This has been investigated by Clemmell,¹ Clevenger,² Holt,³ and others, but more particularly in reference to the treatment of silver ores. The general conclusion appears to be that its use in silver-ore treatment is decidedly beneficial, and also to a lesser extent in gold ore, but that it is necessary to add the correct quantity as an excess may be injurious; no specific rule, however, is given for determining the correct amount, nor is any reason advanced as to why an excess may prove injurious.

Experiments made on the roasted ore discussed in this article showed that the addition of CaO improved extraction—adding lead acetate in addition to CaO gave a further improvement, but the best extractions were obtained by adding acetate and omitting lime, at a cost, however, of greater cyanide consumption. It should be noted that in these tests no soluble sulphides were detected either before or after treatment.

Somewhat different results were obtained by two tests in which roasted ore was agitated with solution foul with soluble sulphides. It would appear that under the conditions, in a solution containing little or no protective alkali, the use of acetate in just sufficient quantity to precipitate soluble sulphides, is beneficial, but may be injurious in the presence of much CaO , especially if the acetate be in excess. The effect of adding acetate to solutions containing soluble sulphides is, that of the precipitated sulphide be removed by filtration, a considerable increase in solvent activity ensues, but that the presence of PbS renders solutions containing any protective alkalinity almost incapable of dissolving gold, even

*Abstract from *Monthly Journal* of Chamber of Mines, Kangaroo, Western Australia.

³*M. & S. P.*, Apr. 17, '09.

power is only imperfectly restored by neutralizing the protective alkalinity.

The reaction assumed to take place between PbS and KCN is a reducing one

To ascertain how far the above reaction proceeded, a weighed quantity of freshly precipitated PbS was added to a freshly prepared solution of NaCN of definite strength, and agitated for 16 hours with excess of air and with high and low protective alkalinity (CaO). It was found that with low P.A. all the PbS was apparently oxidized, but that much remained unoxidized with high P.A. Strong traces of NaCNS were formed with low, and less with high P.A., but in neither case had any large proportion of the sulphur contained in the PbS, combined with NaCN to form NaCNS. With high lime content much remained unaltered, and with low lime the dissolved air had probably largely oxidized the sulphide to sulphate. In neither case was the formation of NaCNS commensurate with the weight of PbS added; this was shown by titrating the solution for NaCN and observing the loss due to formation of thio-cyanates.

The general results of several tests on the effect of adding lead acetate to solutions containing soluble salts, PbS removed by filtration or left in, and P.A. present or neutralized, are materially different from those obtained by treating roasted ore with cyanide solutions containing CaO, lead acetate, etc.

Another lot shows the effect of addition of acetate to solutions prepared from NaCN and pure CaO, and to mill solutions free from soluble sulphides, but containing other sulphur compounds, as thio-cyanates, thio-sulphates, etc., ferro-cyanides being present in traces only. It is remarkable that the addition of so small a quantity of lead acetate as 0.0025% should have so great an adverse influence on solvent activity, such influence being shared by PbS and PbO. That alkali increases the effect of such compounds is doubtless because it increases their solubility, but it is certainly remarkable that similar results should not occur when treating ores containing notable amounts of galena, cerussite, etc. Galena, for instance, is a frequent constituent of ores in the Menzies district, its presence usually indicating high gold-content; or lead compounds are also present in many of the oxidized ores there, but they give no special trouble in cyanidation.

Further experiments on the effect of varying alkalinity, both on mill solutions, containing—as before—thio-cyanates etc., and on pure solutions, showed that neutralization of protective alkalinity in some cases increases solvent activity and addition of CaO depresses it; and if the total alkalinity of mill solutions is neutralized, using phenol-phthalein as an indicator there is a large increase in their solvent activity.

JUDGE GARY'S ADVICE. To employers of labor I would say: Treat your men right; treat them justly and liberally. To employees I would say: Loyal, efficient service is sure to be rewarded. Do not permit outsiders to in-

fluence you to act contrary to your own interests. To both employer and employee, I would emphasize the fact that each must rely upon the other for success; neither is independent of the other; they succeed or fail together.

Definition of the Term Potash

*To meet the numerous inquiries that have been addressed to the U. S. Geological Survey regarding the exact meaning of the terms 'potash,' 'actual potash,' and 'potassium,' the following explanation is given:

The element potassium, represented by the symbol K, is the basis of all potash salts or compounds. This substance is a metal; that is, it possesses metallic properties. To prevent rapid change it must be kept from air and water, with both of which it combines with great avidity. Combined with oxygen it forms potassium oxide, represented by the symbol K_2O , known as potassa, but popularly as potash. In estimating the quantity of potassium in the different products of the Stassfurt (Germany) deposits, this compound, K_2O , is employed as a standard, the object being to establish a basis of comparison for all potassium salts. Among chemists as well as laymen there has grown up the practice of using for this standard the term 'potash.' When only the term 'potash' is used in speaking of potash products, it is understood to refer to the potassium oxide (K_2O) present. As a matter of fact, however, potash salts are not sold in the form K_2O , but as the sulphate or the chloride. By the term 'potassium sulphate' is meant potassium (K) combined with the acid radicle of sulphuric acid (SO_4), or potassium oxide (K_2O) combined with sulphur trioxide (SO_3), making the compound K_2SO_4 . By potassium chloride is meant potassium (K) combined with another element, chlorine (Cl), and represented by the formula KCl.

In the following table are given the percentages of the element potassium, and also of the combination known as potash in or obtainable from the common potassium compounds and minerals:

Name and symbol Element:	Percent- age of potassium (K)	Chemical equivalent in terms of potash (K_2O)
Potassium—K	100	120
Potassium salts or potash salts:		
Potassium chloride (mineral syl- vite)—KCl	52	63
Potassium muriate (same as chlo- ride)		
Potassium sulphate— K_2SO_4	45	54
Potassium nitrate (saltpeter)— KNO_3	39	47
*Potassium carbonate— K_2CO_3	57	68
Potassium hydrate or caustic pot- ash—KOH	70	84
Potassium cyanide—KCN	60	72
Stassfurt minerals:		
Carnallite— $\text{KMgCl}_2 \cdot 6\text{H}_2\text{O}$	14	17
Kainite— $\text{MgSO}_4 \cdot \text{KCl} \cdot 3\text{H}_2\text{O}$	16	19
Sylvite (potassium chloride)—KCl	52	63

*The term 'potash' is often applied to this compound.

*Abstract from 'Potash Salts, 1915,' by W. C. Phalen.

The Ketchikan District, Alaska

By Emil Edward Hurja

Ketchikan's copper mining industry has taken a new lease on life, by help of the higher price for the metal. Six properties, all of them on Prince of Wales island, are shipping regularly. The total tonnage per month from these six properties amounts to 12,000 tons, with odd shipments from prospects and mines undergoing development. Three hundred men are employed.

The district is still in the development stage. Examinations are being made in many localities, the most interesting being that of the Alaska-Gastineau party in charge of F. B. Hyder, of Juneau, Enoch Perkins and O. P. Rogers assisting. This party has been examining properties in and about Ketchikan since May 1 and during the six weeks following visited nearly all of the prospects in the district. Some options have been taken and further inspection of some of the claims is being made. Other exploratory work is that of the Lakinaw-Tagish company, in charge of J. L. Harper.

The principal mining is being done by the Granby Consolidated Mining, Smelting & Power Co. on the Mamie and It claims. Both of these claims, together with a third, the Dean, on which work has been suspended, were taken up by the Granby company in 1913 on working options. Both claims have since been paid for by ore taken out during the course of development. The work of the company is in charge of Nelson W. Sweetser. W. J. Coulter is foreman at the Mamie mine, and Bert Ross at the It. The Granby holdings are on Kasaan peninsula, near Hadley, 30 miles north-west of Ketchikan. The Mamie mine, which is shipping at the rate of 6000 tons per month to the Anyox smelter, has 2500 ft. of workings. Eighty-five men are employed. A Riblett aerial tram 7200 ft. long carries the ore from the mine to the bunkers at Hadley, where ocean-going scows are loaded and conveyed by tugs to the smelter. The ore, chalcopryite in a silicious and magnetite gangue, occurs in large lenses. The largest lens is 300 by 100 ft. The It, upon which the final payment of a \$50,000 purchase

price was made on May 1, has shipped 15,000 tons during the past year. Thirty men are employed. The work of the past year consists of 1000 ft. of drifts and raises and 1500 ft. of diamond-drill holes. Diamond-drilling is still going on at the It and the Mamie to determine the extent of the orebodies. The It is shipping at the rate of 1000 tons monthly.

The Mt. Andrew mine, at the head of Kasaan bay, 27 miles from Ketchikan, is shipping 1500 tons per month.

TUG 'COMMODORE' LEAVING HADLEY WITH SEA-GOING BARGE LOADED WITH 2500 TONS OF COPPER.

The group consists of 21 claims, owned by the Mt. Andrew Mining Co. of New York. The claims were bonded on June 1, 1915, by W. J. Rogers, who is now directing the mining operations. The adits aggregate 7000 ft. Total shipments from the property amount to 90,000 tons. The principal development work is an adit that increases the depth on the orebody from 150 ft. to 460 ft. This 'tunnel' lacked 80 ft. of being the necessary 1560 ft. in length to reach ore on June 16. The deposit contains magnetite and chalcopryite, with some gold and silver. Twenty-nine men are employed. New buildings will be started soon. The property is situated at an elevation of 1300 ft. above sea level. The ore is conveyed to the dock in a Riblett aerial tram 4200 ft. long. Engineers of the Alaska-Gastineau company are conducting an examination of the property. The Mt. Andrew mine is on the border of the same eruptive as the Mamie. Axel Carlson is superintendent.

Rush & Brown, on their claims at the head of Kasaan bay, are mining from a contact metamorphic lens of magnetite ore containing chalcopryite, and shipping at

the rate of 500 tons monthly to the Anyox smelter. They are employing 25 men. Recent work on the Rush & Brown property consists of a winze and drifts from the winze. The orebody has been picked up below a fault. The lowest level on which work is being done is 250 ft. below the surface. A narrow-gauge railroad connects the mine with the bunkers and dock at Kasaan bay. On May 29, Rush & Brown shipped 800 tons of ore on the ship *Granby*. John Wilcox is superintendent.

The Goodro property, on Karta bay, one mile south of the Rush & Brown mine, has 700 tons of ore ready for shipment. No new work has been done on this claim. Ore is being broken from the 100-ft. level to the surface. Ten men are employed. The ore is bornite disseminated in gabbro. It also carries some native gold.

Development work is being carried on steadily on the Valparaíso group of gold claims near Dolomi. The group is operated by the Princeton Mining & Milling Co., with B. A. Eardley as manager. Ed. C. Morse has charge of the 10-stamp mill, together with a Chilean mill.

The Lakinaw-Tagish Co., of which J. L. Harper is manager, has taken options on the Westlake-King property, known as the Portland group, on the north arm of Moira sound, as well as on the Cymru mine, in the same locality. On June 2 a bond was taken on the Portland group, upon which \$6000 worth of work has been done. No shipments of ore have been made as yet. Assays show zinc, lead, copper, and silver, in a fissure-vein 4 ft. wide. The maximum depth attained is 130 ft. As zinc is the principal ingredient of the ore, shipments will be made to Oakland, Cal., where special treatment will be given. At the northern end of the property is a gold-lead deposit, from which shipments are planned to the Trail, B. C., smelter. Ore mined from the Portland group is conveyed 1000 ft. on an aerial tram to Mineral lake, taken across the lake $1\frac{1}{2}$ miles with scows to connect with the Cymru tramway. Five hundred tons of ore has been mined and is ready for shipment by July 15. A compressor plant and air-drills will be available soon, and the tram extended around Mineral lake to avoid the water-haul. Ten men are employed.

On the Cymru property a shaft has been sunk 100 ft. A three-drill compressor is in operation, as well as a gasoline hoist. A one-mile narrow-gauge track with gasoline locomotives connects the mine with tide-water. Three hundred tons of ore will be shipped to the smelter at Tacoma early in July.

In the Portland Canal district, everything is quiet. The season has been backward and all exploratory work has been retarded. The Alaska-Gastineau company has an option on the Missonri group of claims, on which some work will yet be done. H. R. Plate, representing the Hermosa Issues Co. of New York, has given up his bond. Access to these prospects, which are on the British Columbia side of the line, is obtained through the Salmon River valley.

The Alaska Venture Syndicate, of London, a subsidiary of the Great Boulder Proprietary, of Western Australia, has suspended work on the Old Glory claims

at Smuggler's cove on Cleveland peninsula, 25 miles north of Ketchikan. The original owners of the claims were Martin Bugge and associates. Development work done on the property after the spring of 1914 consists of surface stripping and prospecting. Improvements on the claims aggregated \$150,000. The work is held in abeyance because of the War.

It is reported in Ketchikan that Catlin, owner of the Sunshine silver-lead property on Cholmondeley sound, is to resume work soon. Over 150 tons of ore is on the dump, ready to ship.

The It Mining Co., of which H. C. Strong is president and J. L. Barber secretary, is planning to develop the Gold Stream property, consisting of the Gold Spring and Gold Stone claims, on Gravina island, opposite Ketchikan, three miles from the town. Work on the lode, which contains gold, consists of 150 ft. of shaft and 300 ft. of tunnel work.

W. H. Gilmore and Fremont King, owners of the Sea Level property, near Ketchikan, have bonded it to Carl B. Lancaster, of Seattle, with whom are associated C. H. Black and Carl Strong. The property shows a vein varying in width from 2 to 10 ft. and carrying free-milling gold ore. The Sea Breeze claim, which adjoins the Sea Level property on the east and carries a continuation of the Sea Level vein, will be opened up through the Sea Level workings, which have been unwatered. Four men are employed under Carl B. Lancaster. The workings of the Sea Level run to within 150 ft. of the Sea Breeze line. A small hoist is in use. A Fairbanks-Morse semi-Deisel 25-hp. engine and a Fairbanks-Morse compressor have been bought and will be on the property when the work is farther advanced. The Sea Level has a 30-stamp mill built in 1907 but not used for many years.

The Goo Goo group of gold claims, owned by Richard Nuekolls and associates, and situated near the Sea Level, have been examined by Alaska-Gastineau engineers. Nine tons of samples were taken on June 15.

M. M. Reese has discontinued work on the Dunton property near Hollis. Development at the Ready Bullion continues. Exploratory work on other prospects in the same vicinity is being carried on steadily. But little more than assessment work has been done on the promising Lucky Nell group, situated 8 miles from tide-water at Hollis. Thirty tons of this ore yielded \$46 per ton in 1913. Since that time no shipments have been made. Polson & Jekis are continuing work on their copper and gold property at McLean arm, 40 miles from Ketchikan. Two chalcopyrite deposits are exposed.

Mining on the west coast of Prince of Wales island, which also is tributary to Ketchikan, is based almost entirely on copper ore. The oldest regular producer in the district is the Jumbo, near the head of Hetta inlet. This mine is operated by the Alaska Industrial Co., of which Senator Charles A. Sulzer is active manager. Shipments are being made regularly at the rate of 150 tons per month. The ore, chalcopyrite in lime, epidote, and garnet gangue, is practically neutral and is easily smelted. Shipments are made to Tacoma. A total depth of

700 ft. has been made possible with connected adits. From the lowest a winze has been sunk 200 ft. From this depth stoping is now being carried on. The winze is being sunk another 100 ft. to connect with a lower adit. Surface exploration of the western end of the Ambo deposit has been encouraging. Senator Sulzer expects

Senator Sulzer is erecting an Allis Chalmers table mill for the reduction of barite from a deposit that he discovered near Lime point. Several hundred tons of this product was shipped last year, with satisfactory results, so Senator Sulzer plans to treat the ore at home. The deposit is over 100 ft. wide. — Sweet brothers are oper-

STOPE IN THE TI MINE, KASAN, PUNJUT.

to open up that end of the orebody next, building short aerial trams to connect with the main Lascien aerial tram, which carries the ore a distance of two miles to the bunkers. A saw-mill has been purchased and new quarters and other buildings will be built. W. L. Moore, formerly with the Alaska-Juneau at Juneau, is superintendent of construction. Robert Pollock has been made mine superintendent.

ating the mine of the North and Development Co. at Big Harbor, under a bond. A shipment of 150 tons was recently made to the smelter at Tacoma. The ore is a massive perite containing no pyrite. Assays of ore from the latter of a few shipments yielded 60 to 65 percent barite. The head of K. etc. let's us see the first 87.0 percent. This property is owned by C. A. Sulzer, of P. A. etc. recently over 100 ft. Big Harbor property is owned

ed the Gould claims on the south end of Suquan island. He has a small force of men employed in exploratory work.—W. H. Link and J. W. Rickenback, of Seattle, arrived recently on the *Curacao* and have resumed development work on their property adjoining the Red Wing at Copper City. John Spaeth, George Bureh, and John Wileox have prospected and made new locations of copper claims at Hunter's bay.

Prospecting has been given an impetus by the successful operation of a number of properties. The district can stand prospecting, however, for the total area of the Ketchikan mining district is 9370 square miles, of which 2800 square miles is represented by Prince of Wales island alone.

COPPER is said to have derived its name from the island of Cyprus, whence the Romans obtained their supplies of copper ore.

Explosives

Explosives are classified by the Bureau of Mines into four groups: ammonium-nitrate explosives; hydrated explosives; organic-nitrate explosives other than nitroglycerine; and nitro-glycerine explosives.

Ammonium nitrate itself is not an active explosive, but under particular conditions, such as a strong detonator, is capable of explosive decomposition. When pure it has no practical application for blasting, but needs the addition of 'sensitizers.' These sensitizers may themselves have explosive qualities, as nitro-glycerine or nitro-cellulose, or they may be non-explosive such as resin, sulphur, flour, sugar, oil, paraffin, or coal. A large number of commercial explosives are included in the ammonium-nitrate group.

Hydrated explosives are those that depend largely

upon the cooling effect of the water of crystallization to reduce the flame temperature for their safe use in coal mines. The hydrated salts employed to furnish the water of crystallization are Epsom salt or potassium alum. The hydrated explosives contain nitro-glycerine as the principal explosive ingredient, and most of them also contain ammonium nitrate. Only a few commercial explosives are in this group.

The third group, the organic nitrates, includes explosives containing 'nitro-starch' (starch nitrate), or a similar organic nitrate as the characteristic ingredient. Starch is a carbo-hydrate, of the composition $C_6H_{10}O_5$. Nitro-starch explosives are known to mining men as being the explosive sold by one or two manufacturing companies in particular. When used alone, nitro-starch liberates the dangerous carbon-monoxide gas, but by the addition of oxidizing compounds in the manufacturing

this disadvantage is reduced. The Nevada Consolidated Copper Co. uses a good deal of nitro-starch explosive in its open-pit blasting.

The fourth group, nitro-glycerine, includes all explosives whose characteristic ingredient is nitro-glycerine and which are not included in the class of 'hydrated explosives.' Various ingredients are used with the nitro-glycerine, either an absorbent neutral base such as infusorial earth for the making of 'straight dynamite,' or the active gum-cotton which dissolves in the nitro-glycerine to make gelatine. A great many of the commercial explosives belong to the nitro-glycerine group.

THE STEEL HELMETS used in the French army to protect the heads of soldiers are only one millimeter (1/25 inch) thick and are surprisingly light. They are made of the best half-hardened sheet steel.

Principles Underlying Flotation

By Joel H. Hildebrand

INTRODUCTION. *The phenomena involved in ore flotation are mostly effects of surface tension, so that an understanding of this force and how it may be modified by various factors is fundamental to a scientific study of flotation.

Wherever different phases are in contact we have surfaces where the effects of surface tension may be apparent. It will be convenient, for our purposes, to classify the boundaries between phases as follows: (1) liquid-gas, (2) liquid-liquid, (3) liquid-solid. The boundaries solid-gas and solid-solid will not be considered, being unimportant from the standpoint of our sub-

junct size. A general idea of the magnitude of this force may be obtained from the values given in Table I.

TABLE I

Liquid	Temperature, °C.	Surface Tension, Dynes per Cm.
Hydrogen	-252	2
Carbon di-sulphide	20	33.5
Alcohol	20	22
Water	20	73
Ether	20	16.5
Mercury	18	436
Gold	1070	612
Sodium sulphate	880	187

FIG. 1.

ject. Since the effects of surface tension are increased as the surface between the phases increases in extent, we will be led to consider the systems encountered in flotation processes, in which one of the phases is highly dispersed. These systems, corresponding to the above classifications are (1) foams, in which the gas is highly dispersed in the liquid (the other system, fog, in which the liquid is dispersed in the gas does not here concern us); (2) emulsions; (3) suspensions.

LIQUID-GAS BOUNDARY. (a) *Definition and Measurement of Surface Tension.* It is found that all liquids have a tendency to assume a form which will have the smallest surface. Where the liquid is supported by a surface that it does not wet it tends, for example, to assume a spherical form, manifest especially with small drops, where the influence of gravity is small. A soap-bubble tends to contract, expelling the air through the orifice of the pipe from which it is blown. A liquid that wets the walls of a tube will be drawn up into it. The magnitude of this force can be measured by various methods, such as the rise in a capillary tube, the shape of a drop under the opposing action of surface tension and gravity, the weight of a drop that surface tension will support as a liquid issues slowly from a tip of defi-

(b) *Cause of Surface Tension.* It must be noted that we can define and measure surface tension without making any assumptions whatever as to what causes it. The fact that the surface tends to contract with a definite force does not mean that the surface is coated with anything like a rubber membrane. The surface of a liquid, except for a slight difference in density, is doubtless the same as the rest of the liquid. The existence of surface tension is to be attributed to inter-molecular attraction. Consider a molecule, such as *a* in Fig. 1, in the interior of a liquid. It will be attracted by the surrounding molecules, and these attractions may be resolved axially into four equal components, as shown in the figure. Consequently nothing but viscous resistance would oppose the moving of this molecule to another portion of the liquid, provided it remains in the interior. The moment, however, it approaches sufficiently near the surface, the upward component of molecular attraction is reduced, becoming zero at the surface at *b*, if we neglect any effect of gas or vapor above the surface. The result is that we have to do work upon each molecule brought from the interior to the surface of a liquid, and any considerable extension of its surface involves the doing of a considerable amount of work against a force the component of which along the surface of the liquid we call 'surface tension.'

(c) *Effect of Temperature.* Since the increase in kinetic energy of the molecules with temperature forces them farther apart we should expect inter-molecular attraction and hence surface tension to diminish with increasing temperature, and such is indeed the case. At the critical temperature, where the density of the vapor becomes the same as that of the liquid, the surface tension becomes zero, of course.

(d) *Effect of Dissolved Substances.* The surface tension of mixtures of liquids is usually less than that which would be calculated on an additive basis, so that the more general tendency is for solutes to lower the surface tension of the solvent. We find that the surface

*Abstract of an illustrated lecture delivered before a joint meeting of the San Francisco section of the American Institute of Mining Engineers and the California section of the American Chemical Society, February 15, 1916.

tension of water is usually raised by dissolved salts, and lowered by other liquids, and especially by organic colloids, such as albumen, glue, soap, saponin, etc. Moreover, it is possible to show thermo-dynamically that solutes which lower the surface tension of the solvent tend to concentrate at the surface, still further lowering the surface tension there. For this reason very different figures are obtained for static and dynamic measurements of surface tension with solutions of such sub-

FIG. 2.

stances. Table II shows the results of such measurements with sodium oleate (soap) solutions.

TABLE II

Concentration, %	Surface Tension, Dynes per Cm.	
	Static	Dynamic
0.025	55	79
0.25	26	79
1.25	26	62
2.5	26	58

It will be seen that where time is allowed for the concentration of the soap at the surface the tension is much less than in the dynamic method, where no time is allowed for the effect to be manifest. This behavior is exceedingly important in connection with the stability of foams, emulsions, etc., as we shall see.

(e) *Stability of Foams.* Since the production of a foam (or a mist) from a liquid involves an enormous increase in surface, and consequent performance of work against surface tension, such a system is unstable unless

FIG. 3.

stabilized by some means. Drops or bubbles tend to coalesce, hence pure liquids never foam. To produce a stable foam requires a film that is stable. The chief condition for this is the presence of a solute that will be strongly adsorbed at the surface of the solution, lowering its surface tension, as explained above. How this will give a stable film may be understood by the aid of Fig. 2, which represents a film of solution, the shading indicating the greater concentration at the surface. If such a film should be stretched, becoming thinner at some portion, as at *a*, the new surface formed by the stretching would contain less solute, the time not being sufficient for adsorption, and hence would be stronger than the old surface. It is obvious that such a film would be stable, automatically becoming stronger whenever rupture is threatened. This is the action of the foaming agent, such as pine-oil, used in flotation processes. Here,

of course, a foam of great stability is undesirable, as it must be broken down later.

Other factors of minor importance in foam stability are viscosity, which retards the draining of the film (hence the frequent addition of glycerine to soap bubbles); small volatility, preventing evaporation of the foam where exposed to the air, and the protection of the bubbles from coalescence by the forming of a skin or armor about them. The particles of solid ore present in the foam in flotation processes undoubtedly act in this way.

LIQUID-LIQUID BOUNDARY. Much that has been said applies here. Methods of measurement are similar. The magnitudes of these interfacial tensions are illustrated in Table III.

TABLE III

Boundary	Surface Tension, Dynes per Cm.
Mercury-water	379
Benzene-water	33
Turpentine-water	12
Methyl alcohol-carbon di-sulphide.....	0.82

This surface tension becomes zero at the critical temperature of mixing of the liquids, and it is affected by dissolved substances according to the same principles as apply to the simpler systems.

(a) *The Spreading of Drops.* The spreading of drops of oil upon water to form an exceedingly thin film is familiar to all. Whether or not this phenomenon takes place depends upon the magnitudes of the three surface tensions indicated in Fig. 3, which represents a drop of a lighter liquid placed upon a heavier one with which it does not mix. Obviously the drop will spread out over the surface whenever the surface tension represented by *a* is greater than the sum of *b* and *c*. When $a < b + c$ the drop will remain in lens form upon the other liquid. One of these cases may be converted into the other by the addition of suitable solutes to one phase. For example, although oil usually spreads upon water, where the surface tension of the water is much lowered, as it is in meat-broth by the presence of albumen, gelatin, etc., the value of *a* is small enough to allow any oil present to remain as lens-shaped drops.

(b) *The Stability of Emulsions.* This is obviously favored by a low surface tension between the phases, by viscosity, by the presence of a substance tending to form a skin preventing the droplets of the enclosed phase from coalescing, as they naturally tend to do, and most important of all, the presence in the phase that is to enclose the other of a substance that will be positively adsorbed at its surface, thus making stable a film of the liquid separating two droplets of the other, enclosed, liquid. The enclosed phase takes the place of the bubbles in the previous discussion of foam stability. By a suitable choice of solutes either phase may be made the enclosed phase. For example, when soap is added to water the films of water become stable, and a liquid like benzene may be made to form a stable emulsion in water. On the other hand, when a calcium soap is dissolved in benzene films of benzene become stable, and

benzene will yield both stable foams and stable emulsions with water as an enclosed phase.

LIQUID-SOLID BOUNDARY. With a boundary of this sort direct measurement of surface tension is impossible, but relative values may be inferred by noting the wetting power of a liquid for a solid, especially as indicated by the angle of contact. When, for example, a drop of water is placed upon a bright metal surface, instead of spreading over the surface of the latter as would kerosene, it remains in drop form, its surface meeting the metallic surface at a certain angle. When a drop of castor-oil is placed upon the metal it forms a much flatter drop, the angle being different, corresponding to greater wetting power for the metal. The surface tension between these phases can be altered as before by the addition of adsorbed solutes, so that a drop of soap solution will be much flatter when placed upon the metal than the drop of pure water. This wetting power is also different for the same liquid upon different solids, as is illustrated by the experiment shown in Fig. 4, where the angles of contact indicate that when chloroform and water are in competition the former has greater wetting power for a metal surface, while the latter has greater wetting power for glass. It would seem that determinations of these angles should offer a valuable preliminary to flotation experiments.

As a consequence of this relative wetting power, if a layer of kerosene is placed over water, and a powdered siliceous material dropped into the vessel, it will stop only momentarily at the oil-water surface. As fast as the oil can be displaced by the water the particles drop through into the water phase. If, however, a metallic powder, or a sulphide with metallic lustre, be dropped into the vessel, it remains in the oil phase, supported, if the mass is not too great, by the surface tension at the boundary.

The ease with which a solid particle can float on the surface of a lighter liquid depends upon its size, the difference in density of solid and liquid, and the angle of contact the liquid makes with the solid. The relationship is expressed in Fig. 5, where we assume, for simplicity, a cylindrical particle of radius r , height h , and density d_1 , floating on a liquid of density d_2 and surface tension s . The maximum effect that could be exerted by gravity upon the particle would obviously be $\pi r^2 h g (d_1 - d_2)$ dynes. If the solid were not wet at all by the liquid and the angle of contact were zero, the upward force tending to prevent the particle from sinking into the liquid would be $2\pi r s$. In an actual case, however, where this angle is α , the upward force is $2\pi r s \cos \alpha$. It is obvious that the floating tendency would be greater the smaller the particle, the less its density relative to that of the liquid, the greater the surface tension of the liquid, and the smaller α . In floating practice the densities are not to be altered, the size of the particles is made as small as is consistent with economical grinding and subsequent recovery, the surface tension of the water cannot be increased, but is rather decreased by the agent added to produce foaming. The foaming gives a large

surface, as the total quantity of ore floated is proportional to the surface of the water and not to its volume. The most effective modification that can be made in the above factors is to decrease the angle α as

much as possible for the ore particles, while still leaving it greater than 90° for the gangue particles, the condition necessary that the latter should sink. This is the purpose of the small quantity of oil added during the grinding of the ore. The wetting power of oil for a metallic surface causes the oil, if the right kind, to spread over the metallic surface as it would over the surface of water. The water present at the same time wets the gangue preferentially, preparing for the separation that results when the large amount of water is added. It is obvious that the frothing agent necessarily added later works against the effect here desired of the least possible wetting of the ore, as it decreases the surface tension both at the liquid-air and at the liquid-solid surfaces.

A word might be said in conclusion about the stability of suspensions. Besides the stabilizing influences important in the case of foams and emulsions, another here rises to great importance, namely, the electric charges on the suspended particles due to adsorbed ions. This effect may be illustrated by dividing a suspension of fine silica into two portions, and adding to one a little acid and to the other a little alkali. It is found that in the second

FIG 4.

FIG 5.

case the suspension is quickly flocculated and settles out, while in the acid solution it remains suspended for a long time. Reference must be made to works upon colloids for further discussion of the many interesting phenomena connected with such behaviors. In ore flotation, the effect of even slight amounts of acid or alkali may be, aside from that just mentioned, to clean the ore particles and thus expose a more truly metallic surface to the oil, and to affect the surface tensions involved, especially by modifying chemically the other substances added, notably the frothing agent.

The Flotation of Oxidized Ores

By O. C. Ralston and Glen L. Allen

INTRODUCTION. *Concentration of natural sulphide ores by the flotation process has met with such success that attempts have recently been made to apply the process to the flotation of ores other than natural sulphides.

As inquiries on this subject are frequently received by the Bureau of Mines, it has been thought best to publish a summary of the results so far obtained from the experimental work on oxidized ores at the Salt Lake City station of the Bureau, in co-operation with the department of metallurgical research of the University of Utah. The work has been directed by O. C. Ralston, assistant metallurgist of the Bureau, and was carried on for the most part by G. L. Allen; N. C. Christensen and R. W. Johnson assisted.

As above stated, this paper is only a summary, or a preliminary report of the experiments on the flotation of oxidized ores. More complete details as regards the flotation of carbonate ores of lead will be given later, and in the near future the Bureau expects to publish a still more complete discussion on the flotation of oxidized ores of lead, copper, and zinc.

Most of the experimental work in the laboratory at the Utah station has been with the oxidized ores of lead. Only minor attention has been given to the oxidized ores of zinc and of copper for the following reasons: little success has been had with the zinc ores; many others are engaged in testing copper ores, so that there was no pressing necessity for experimentation with copper ores by the Bureau, although an attempt is being made to co-ordinate the work of those who are willing to join in solving the problem. Flotation of oxidized minerals depends upon a preliminary 'sulphidizing' by any method that will convert at least the surface of the mineral particles to a sulphide of the metal. This step is followed by flotation of the artificial sulphide, which results in a concentration of the valuable metals in the low-grade oxidized ore being treated.

The methods of sulphidizing that have been investigated are as follows: (1) By the use of hydrogen sulphide on either the dry or the wet crushed ore, (2) by the use of solutions of the various sulphides and sulpho-compounds of sodium, (3) by the use of solutions of the various sulphides and sulpho-compounds of calcium, (4) by the use of sulphur vapor, (5) by the use of a sulphuretted oil, (6) with colloidal sulphur.

It has been found that treatment by some of these methods will form a film of sulphide over the surface of the particles of such minerals as lead carbonate or copper carbonate, whereas in other cases the mineral particles are sulphidized to the core. Other methods failed

CARBONATE OF LEAD ORES. All of the above methods of sulphidizing have been tested on a great number of lead-carbonate ores. Some of these ores contained silver and some contained lead as the principal metal. A number of the ores have been successfully concentrated and others refuse to yield to concentration by flotation. In general, a high alumina content (acid soluble) in an ore seems to prevent the application of sulphidizing and flotation. The purpose of this report is to give the main features of the flotation of oxidized ores of lead, as well as other ores.

In sulphidizing with hydrogen sulphide gas, as applied to the lead-carbonate ores, it was found that the best method of applying the gas to a dry powdered ore was in a tumbling barrel with the gas inlet in the end. Sulphidizing in a glass bottle showed that the ore blackened quickly after the application of the hydrogen sulphide gas. On attempting to float out lead sulphide from the ore as soon as it had blackened it was found that a low extraction of lead was obtained and likewise a low-grade concentrate, unless the pulp was previously acidified with sulphuric acid. By acidifying the pulp, a cleaner concentrate was floated, but the extractions of lead remained low. Only by prolonged treatment with hydrogen sulphide gas could the extraction of the lead be raised to commercial grade. With a number of ores eight hours' treatment gave an extraction of over 80% of the lead.

The use of hydrogen sulphide was considered for the reason that it can be generated quite cheaply. With iron matte available at \$5 to \$10 per ton, and sulphuric acid at from \$5 to \$10 per ton, the cost of the hydrogen sulphide resulting, including labor, etc., is between \$30 and \$50 per ton. If this gas in combining with the metal in the ore produces only a superficial film of sulphide, and does not penetrate to the centre of the particles, it might be possible to make a ton of the gas sulphidize many tons of ore.

Unfortunately hydrogen sulphide attacks the metallic particles of the ore with such avidity that by the time the latter are sulphidized sufficiently to permit of good extraction by flotation, they have also been sulphidized to the core, and practically a chemical equivalent of hydrogen sulphide, to the lead in the core, has been absorbed. Even coarse pieces of ore in a bottle absorb the gas with evolution of heat, and on breaking open the pieces the black coloration is seen to have traveled deeply into the particles.

Owing to the fact that the value of the lead concentrate obtained is very low as compared to the amount of hydrogen sulphide necessary to sulphidize it, this process is not regarded as commercially practicable.

*Issued by the U. S. Bureau of Mines.

Application of hydrogen sulphide to the ground ore suspended in water does not seem to be subject to the same difficulty. True 'filming' of the particles with lead sulphide seems to take place, and the extractions possible after a short treatment with the gas are satisfactory. The speed of travel of molecules of hydrogen sulphide gas, as compared with the speed of travel of the same molecules in solution affords an explanation of the difference in the action of the gas when applied to dry pulverized ore as compared with its action when applied to pulp suspended with water.

The best results on lead-carbonate ores have been obtained when sulphides of sodium were used for the sulphidizing agent. The sodium sulphide must necessarily be introduced in solution and seems to cause true filming. The sulphides of sodium considered commercially applicable are the normal sulphide of sodium, Na_2S ; sodium poly-sulphides, Na_2S_x , and Na_2S_5 , and the sulphhydrate of sodium, NaSH . Of these, the last, the sulphhydrate, seems to be effective, as is evidenced by the quicker blackening of the pulp, and the deeper blacker color formed. The normal sulphide is almost as effective; the poly-sulphides seem to be the least active. Different ores require 10 minutes to 24 hours of contact with the solutions of sodium sulphide, depending on the properties of the ore and on the strength of the solution. Amounts of sodium sulphide varying from 10 to 20 lb. per ton of ore are usually sufficient, and should be applied to pulp containing about one ton of water per ton of ore, in order that the solution may be as strong as possible during the sulphidizing stage of the process. After a good black color has developed and the color has ceased to increase in blackness, the pulp is diluted with water to a 3:1 or 4:1 mixture and floated in either mechanically agitated or pneumatic machines. The market for sodium sulphide is limited and it should be obtainable at considerably less than 2 cents per pound.

The poly-sulphide of calcium, obtained by boiling powdered sulphur with slaked lime, seems to be satisfactory for ores that yield easily to sulphidizing, but is sluggish in its action, as compared with the sulphides of sodium. The normal sulphide of calcium is only slightly soluble and hence its use was discontinued as a possible sulphidizing agent. The sulphhydrate of calcium is the most active of these reagents, but has not been tested to any extent in this work, as there is doubt as to whether it would be commercially feasible to prepare such a compound.

Sulphidizing with sulphur vapor has been tried with little success, for the reason that it must be applied at a temperature above the boiling-point of sulphur in order to prevent condensation of the sulphur. This means that the ore must be heated to a temperature above 445°C . There seems to be no difficulty in obtaining elemental sulphur vapor commercially, as pyrite will give up half of its sulphur content when heated in a closed space, and sulphur di-oxide gas can be reduced to elemental sulphur by passing it through a heated zone in the presence of a reducing agent. As lead itself is easily reduced from its carbonate form, the temperature

might as well be raised to the point where the lead can be liquated out, a reducing atmosphere being used instead of a sulphidizing atmosphere.

The use of a sulphuretted flotation oil, in which loosely combined sulphur is available for combination with carbonates of lead or other metals, and the rest of the oil is then available for 'oiling' the artificial sulphide, has given but little encouragement in the tests conducted by the Bureau. Finally, colloidal sulphur, mentioned as a possible method of sulphidizing, does not seem to combine with lead carbonate at all. It floats as a white lining of the air bubbles in the flotation machine, and brings up very little lead with it.

Usually the precious metals contained in a lead-carbonate ore accompany the lead. We have noticed that the silver extraction will lag behind the lead extraction when the ore is sulphidized with sodium sulphide, and that the reverse has usually been true when hydrogen sulphide was used.

The importance of sulphidizing flotation is due to the fact that there are many deposits of lead carbonate ore in all of the Western States and many of these ores have been milled with varying success. Frequently the lead carbonate can be concentrated satisfactorily by gravity methods, but often it is found that the particles go into the slime and are lost. Tailing heaps containing 5 to 10% of lead are common. The object of this investigation is to determine whether sulphidizing flotation could not be applied to the treatment of the deposits of lead carbonate above mentioned, to prevent the waste that now takes place when these ores are treated by gravity-concentration processes, and render amenable to treatment carbonate ores that are too low-grade to be treated by present methods.

The General Engineering Co., of Salt Lake City, has carried on extensive tests of different lead-carbonate ores with varying success, according to the ore tested. The company owns several sulphidizing methods, which it has either patented or purchased.

A flotation plant to apply sulphidizing and flotation to an ore containing lead, silver, and gold is being constructed by the Prince Consolidated Mining Co., at Pioche, Nevada, for the treatment of two tailing-dumps from former pan-amalgamation and cyanide operations in that vicinity. This plant is expected to be in operation shortly.

OXIDIZED COPPER ORES. Many attempts have been made, both by large operating companies and by other experimenters, to float the carbonate and other oxidized minerals of copper. For that reason the testing of such ores by us has been limited.

Hydrogen sulphide seems to be by far the best medium for sulphidizing oxidized copper ores previous to flotation. When applied to the dry ores we found the same conditions as those mentioned for lead; the particles are sulphidized to the centre, which requires an excessive amount of hydrogen sulphide. Applied to the wet pulp, the hydrogen sulphide seems to cause true filming. Our work has yielded a black concentrate, but we are informed by Mr. J. M. Callow, of the General Engineering

Co., that the company has been able to reduce the amount of sulphur used to a point where the froth is green with slightly coated malachite. He states that as little as half a pound of sulphur per ton of ore is giving good extractions in the plant of the Magma Copper Co., at Magma, Arizona, where his company has put in the first successful installation of this kind.

Sodium sulphide has been tested by a number of the larger companies that have oxidized copper minerals in their sulphide ores. The amount of oxidized copper in such ores is usually a fraction of 1%, so that only two or three pounds of sodium sulphide per ton of ore is necessary. This is usually added to the machines during flotation, or to the mixing-tanks before flotation. Our experience is that if some little time of preliminary contact is allowed before flotation is attempted, better sulphidizing of the material will result.

Calcium poly-sulphide has been used for some time in

a number of the large copper concentrating mills with indifferent success, and seems to be detrimental in some instances. On the ores tested by us fair results were obtained if the calcium poly sulphide was allowed to act until the ore had become well blackened.

It is stated that sulphur vapor was tested at one of the large plants for flotation of oxidized forms of copper and gave better results than any other method of sulphidizing. Of course this method has the disadvantage of having to be applied to dried, heated, and finely divided ore.

Sulphuretted oils are being used at a number of plants to supplement other methods of sulphidizing and considerable secrecy is observed as to the technical details of this work.

So far as we know, colloidal sulphur does not assist in the flotation of oxidized forms of copper. Neither has the silicate of copper been successfully floated by

METHOD OF SULPHIDIZING

- No. 1. Two hours' treatment with H_2S gas on dry ore.
- No. 2. Four hours' treatment with H_2S gas on dry ore.
- No. 3. Eighteen hours' treatment with 1% solution of Na_2S , 20 lb. per ton of ore.
- No. 4. Three hours' treatment with 0.8% solution of CaS_2 , 16 lb. per ton of ore.

sulphidizing flotation. It will blacken when sulphidized, but resists flotation. Possibly it still presents a silicate, rather than a sulphide, surface to the flotation elements. For this reason a number of the large copper companies are seriously contemplating leaching the oxidized copper ores, rather than lose what silicate of copper may be present.

Repeated attempts to float the natural sulphides along with sulphidized minerals have failed, as the sulphidizing agents cause trouble with the flotation of the natural sulphides. By careful adjustment this difficulty has been solved in one plant, though the details are not available.

OXIDIZED ZINC MINERALS. Attempts to float the particles of oxidized zinc, both before and after sulphidizing by most of the above methods, have met with no success whatever in our laboratory experiments. We are informed that some headway was made with the problem by Prof. F. W. Traphagen, at the Colorado School of Mines, but that the sulphide film seemed to come off too easily. However, poor results were obtained, whatever the cause.

Our experience has been that most of the carbonate ores of zinc contain important amounts of the silicate, and this may be one reason for the non-success of this work, for the same reasons that copper silicate will not float.

Direct flotation of oxidized minerals of the kind mentioned, so far as known, has not been successfully accomplished. In all of the successful work witnessed by us there has been some form of alteration of the oxide to the sulphide. A number of parties claim to be successful in the flotation of copper carbonates without sulphidizing, and others in the flotation of scheelite, fluorite, and magnetite. We were unable to verify these statements.

RESULTS OF TESTS. Some of the best results and some average results which have been obtained in the work at the Utah station, are given in the table on the preceding page.

PATENTS. A list of patents dealing with methods of sulphidizing and flotation follows:

U. S. Patent	807,591	Dec.	19, 1905	A. Schwarz
U. S. Patent	1,091,760	April	28, 1914	J. T. Terry
U. S. Patent	1,098,668	June	2, 1914	H. B. Hovland and G. B. Frankforter
U. S. Patent	1,140,865	May	25, 1915	R. F. Bacon
U. S. Patent	1,140,866	May	25, 1915	R. F. Bacon
U. S. Patent	1,159,912	Nov.	9, 1915	H. B. Hovland
U. S. Patent	1,180,816	April	25, 1916	R. F. Bacon
British Patent	26,019	Nov.	10, 1909	H. L. Sulman and H. P. K. Picard

Provisional specifications 28,612, Sulman and Picard, applied for Dec. 7, 1909, and 29,616, applied for Dec. 17, 1909, are incorporated in British Patent 26,019.

THE FOREIGN TRADE of the United States during the fiscal year ended June 30 reached the enormous total of \$6,189,148,585, which exceeds by more than \$2,000,000,000 the trade of any previous year, and compares with a total \$2,241,424,266 in 1900. The excess of ex-

ports over imports during the last fiscal year was \$2,145,082,161, comparing with the ordinary figure before the War of about \$500,000,000 per annum. Of our total foreign trade about 55% is with Europe; of the exports alone, about 65% goes to Europe. Comparing American foreign trade with that of Japan, our exports and imports during one month, May 1916, were more than the whole foreign trade of Japan for a year. Japan's foreign trade is about \$600,000,000 per annum, being less than that of Canada, which, with one-sixth the population of Japan, has a foreign trade of more than \$1,000,000,000. Australia, with 5,000,000 people, has a foreign trade equal to that of Japan. In the same class are China, Switzerland, and Brazil. Great Britain's foreign trade amounts to over \$6,000,000,000 per annum, Germany's foreign trade was about \$5,000,000,000 before the War, that of France is \$3,000,000,000 and the Netherlands \$2,500,000,000.

Platinum Production

Production of crude platinum in California and Oregon in 1915, according to the U. S. Geological Survey, was 741.91 troy ounces, having a value of about \$23,538, an increase of 171.91 oz. over the production in 1914. Californian mines produced most of this quantity; only one mine in Oregon reported production in 1915. The Rambler mine, Albany county, Wyoming, produced platinum-bearing copper concentrate, which was shipped to Eastern refiners. No platinum ore was shipped from the Boss mine, Clark county, Nevada.

According to reports received by the Survey from the platinum refiners, 8665 oz. of new metals of the platinum group was recovered, of which at least 1587 oz. is believed to be of domestic origin. Secondary metals derived from the refining of scrap and sweeps to the amount of 42,970 oz. were sold in 1915.

Notwithstanding the embargo placed on the exportation of platinum by all the Allied governments, United States imports of platinum and allied metals during the year 1915, as compiled by the Bureau of Foreign and Domestic Commerce, Department of Commerce, were only 10% below the 1914 imports, amounting in all to over 69,000 oz., having a value of \$2,768,688.

Figures showing the world's production of platinum and allied metals are at best estimates made from the most reliable information obtainable, and the table below gives the best estimates from information available to the Survey at this time (the figures are in ounces):

Country	1912	1913	1914	1915
Borneo and Sumatra.....	200	200	(*)	(*)
Canada	30	50	30	100
Colombia	12,000	15,000	17,500	19,000
New South Wales	778	1,275	1,248	756
Russia	300,000	250,000	241,200	124,000
United States.....	721	483	570	742
	313,729	267,008	260,548	143,898

*No basis for estimate.

†No figures from Tasmania available at time report goes to press.

Recent Patents

1,178,001. GOLD-SAVING DEVICE. George Edick and John E. Davern, Albuquerque, N. Mex. Filed Sept. 24, 1915.

A device for separating float or flour gold from fine foreign substances, comprising a mercury receptacle, a vertical column extending downwardly into said receptacle and provided with a plurality of sides, a pyramidal deflector extending upwardly into the lower end of the mercury column, said deflector having a series of sloping sides equal in number to the sides of the column and sloping toward the lower ends thereof, the deflector being provided with horizontal flanges defining narrow elongated horizontal exits into the body of mercury, and an inlet at the top of the column.

1,178,081. PROCESS OF CYANIDING. Harai R. Layng, San Francisco, Cal. Filed Mar. 19, 1913.

1. A method of extracting values from ores and recovering cyanid from its solution which consists in first treating the ores with a cyanid solution, then filtering the solution to remove the undissolved residue, conveying the pregnant solution to a sealed receptacle, adding a chemical to liberate cyanid and to precipitate salts of the metals, conveying the liberated cyanid to a recovery device to recover the cyanid, and filtering the remaining solution to recover the precipitated salts.

1,182,951. PROCESS OF DESULFURIZING ORES. Howard F. Wierum, Upper Montclair, N. J., assignor to the Sulphur Syndicate Limited, London, England, a Corporation. Filed Dec. 29, 1914.

1. A process of separating sulfur from metallic sulfids, which consists in first subjecting the ore to a temperature sufficient to distil a larger part of the less stable atom of sulfur present in the raw ore, and in an atmosphere which is non-oxidizing; then passing the ore through another section of the same furnace, in which a highly reducing atmosphere is maintained, and a temperature preferably just under the fusing or melting temperature of the material under treatment; then passing the material through a third section of the furnace, in which an oxidizing atmosphere is maintained, in which third section a greater or less amount of the sulfur remaining in the material under treatment is oxidized and sulfur dioxide, usu-

ally with some trioxid, present, and passing the gases and vapors formed throughout these successive steps in a direction opposite to that of the travel of the ore, thus providing means for the reduction of sulfur oxids formed in the third section of the furnace to be reduced to sulfur in their passage through the second section of the furnace, and also means for preventing either the oxidation or combination with carbonaceous matter of the elemental sulfur distilled in the first section of the furnace, as well as the elemental sulfur produced in the second section of the furnace.

1,183,736. PROCESS OF REFINING COPPER. Edward C. King, Cananea, Mexico. Filed October 22, 1910.

1. The hereindescribed improvement in the art of refining copper in an oxidized condition, which consists in introducing hydrocarbon oil free from oxygen into direct contact with the interior of a body or bath of molten copper while the latter is protected from oxidizing influences.

2. The hereindescribed method of refining copper which consists in introducing liquid hydrocarbon oil free from oxygen into the interior and below the surface of a body of the metal while in a molten state and while in an oxidized condition, and continuing such operation until all the impurities and the oxygen contained in the copper have been eliminated therefrom.

1,183,431. TUBE-MILL. David E. Carlson, Chicago Heights, Ill., assignor to Chalmers & Williams, Inc., Chicago Heights, Ill., a Corporation of Illinois. Filed July 11, 1915.

1. A diaphragm plate for a tube-mill comprising separate plates secured together and adjustable relatively to each other,

said plates being provided with holes the edges of which overlap, the holes of one of said plates being relatively large, and projections on the other plate which extend into said holes, said projections being narrower than the width of said holes and forming sides of free openings in the plate other than that on which they are formed, the opposite sides of said free openings being formed by the edges of the holes in said plate which overlap the edges of the holes in the plate on which said projections are formed, substantially as described.

1,183,226. DRY ORE-SEPARATOR. David M. Owings, Canton, and William R. Kinsey, Bartlesville, Okla. Filed Dec. 16, 1915.

1. In a dry ore separator the combination of a concentrating table having spaced metal receiving channels therein, a hood inclosing said table and open at its opposite ends, means for discharging a blast of air through said hood over said table, means for feeding ore containing material to said hood in the path of said blast, and cylindrical agitators having radially projecting teeth and disposed entirely within said channels to avoid obstructing the surface of the table over which the ore containing air blast is directed.

1,182,890. SEPARATION OF METALLIC SULFIDS. Leslie Bradford, Broken Hill, New South Wales, Australia. Filed Sept. 10, 1913.

1. A process for the preferential or selective separation of zinc sulfids from lead sulfids in ores containing mixed sulfids which consists in submitting the ores to agitation with a frothing agent in a heated feebly acidulated solution of common salt of such a nature as to render the lead sulfid particles immune to flotation while in the said medium but as not to affect the subsequent floatable properties of the said lead sulfid particles by the ordinary flotation treatments and which does not similarly affect the zinc sulfid particles and permits the said zinc sulfid particles to float substantially in the manner hereinbefore described.

1,184,520. ELECTRIC FURNACE PERMITTING THE EXTRACTION IN A STATE OF PURITY OF ZINC FROM ITS ORES. Eugène Francois Côte and Paul Rambert Pierron, Lyon, France, assignors to Société Anonyme pour l'Electrometallurgie du zinc, Procédés Côte, et Pierron, Lyon, France. Filed July 24, 1914.

1. An apparatus for extracting zinc from ores in a state of purity, comprising a furnace for melting the ores, and a refining furnace into which the zinc vapors from the melting furnace are delivered, said refining furnace being provided

with means for condensing the zinc vapors in the form of drops or powder, and with means for re-distilling the zinc drops or powder, whereby the metal will be refined successively with the production thereof while at a temperature next to the point of volatilization thereof.

1,183,986. PROCESS OF CYANIDING. Harai R. Layng, Seneca, Cal. Filed Dec. 29, 1914.

1. A process for regenerating cyanid and recovering values from a cyanid solution containing compounds of valuable metals which comprises treating the solution with suitable chemicals of precipitate cyanogen compounds of the metals, separating the precipitate so formed from the solution, and treating the precipitate with a mixture comprising an oxidizing agent and capable of converting cyanid into hydrocyanid acid, substantially as described.

1,187,822. ORE-CONCENTRATOR. George B. Eberenz and James I. Brown, Cripple Creek, Colo. Filed Mar. 2, 1916.

1. An apparatus for concentrating ores by gaseous flotation of mineral particles in liquid, including an agitating tank and a spitzkasten, the agitating tank having an opening at its base leading into the base of the spitzkasten and an opening leading from the spitzkasten and into the agitating chamber above the base and below the overflow level of the spitzkasten, and an agitator rotating in a vertical plane within the agitating tank and disposed below the plane of the second-named opening, the agitator rotating in such a direction as to draw liquid inward into the agitating tank from the spitzkasten by the upper opening but force liquid from the agitating tank into the spitzkasten by the lower opening, the upper and lower openings being so proportioned as to maintain a liquid level in the agitating tank lower than that in the spitzkasten.

1,185,757. PROCESS OF PREPARING PURE ZINC-SULFATE SOLUTION FROM ZINC ORES. Shunjiro Araki, Osaka, Japan. Filed Sept. 6, 1913.

1. The process of producing a pure zinc sulfate solution from zinc ores which comprises extracting the ores with a sodium bisulfate solution, removing from the solution the heavier metals by treatment with metallic zinc, separating the greater part of the iron and manganese by neutralizing with alkali and by treatment with an oxidizing agent, and removing the remainder of the iron and manganese by adding sodium silicate, neutralizing the sodium silicate with sulfuric acid to form silicic acid and sodium sulfate, and heating the resulting solution containing silicic acid to convert the dissolved colloidal silicic acid into an insoluble form.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

LEADVILLE, COLORADO

PRODUCTION FOR HALF YEAR.—NEW MINES.—LOCAL BUSINESS.—
IOWA GULCH MINES.—DREDGING.

The first six months of the current year shows the Leadville district to have made a record both in ore production, value of output, and in increasing the development of old and new properties. Production in January was approximately 60,000 tons, an average of nearly 2000 tons daily; February dropped to 57,000 tons, but with a daily average equal to that of the previous month; March recorded a small gain with 63,000 tons; April continued the advance with 66,000 tons; May following with 73,000 tons; and June produced 83,250 tons, an increase of 10,000 tons over any previous month. The total output of the district during the half-year is 402,250 tons. Most of the ore has been zinc carbonate and zinc-lead sulphides, both of which have realized high prices during the period. The other ores vary from low-grade iron-manganese to high-grade gold-silver, including several shipments of bullion from the Derry dredge. The estimated value of production is \$10,000,000.

During the term 1 new and 28 old mines resumed operations. Among these, the most important are the Harvard and Tip Top on Fryer hill controlled by the U. S. S. R. & E. Co.; the Mikado on Iron hill, under the management of George O. Argall; the Greenback in Graham Park, owned by Patrick Mulrooney and rated as one of the best mines in the district; and the McCormick on Yankee hill, purchased from the Small Hopes-Boreel Mining Co. by the Empire Zinc Co. The others are smaller properties in all parts of the district, indicating a most unusual revival. The activity reaches from Iowa gulch on the south, through the district into Prospect mountain and East Tennessee gulch on the north, and includes a number of properties on Sugar Loaf to the west, an area that has had little development for years.

A general wave of prosperity due to the mining uplift is also noticeable in business circles. Real-estate men say that the value of property in Leadville has increased at least 10% during the past six months. Good store lots are held at a premium, and there are but few inhabitable residences unoccupied. Property owners have been busy during the spring and summer months repairing old houses, putting them into shape for tenants who are daily coming in from other places. Fully 200 men have been added to the district pay-rolls since the first of the year, and several times that number will find employment as soon as the Down Town and Fryer hill mines begin mining in earnest. The Mikado enterprise will not be ready for development this year but will be a factor in 1917.

The work recently started in Iowa gulch is at present attracting no little interest from local mining men. Steady shipments are being made from the Lilian, one of the oldest properties, and it is stated that the output from the mine is now far greater than it has been for years. Several groups of lessees are developing the property, most of the work being done in the upper levels where many large bodies of carbonate of zinc have been found. Some good gold-bearing ore is also being shipped from the Lilian, and present indications are promising.—The First National, also one of the early day mines of Iowa gulch, is producing a regular tonnage of lead-zinc ore containing good value in gold and silver. This makes it the best policy of the operators to ship the material as a

lead-silver ore rather than a lead-zinc combination, although a good price could be secured for the latter.—The Continental Chief, one of the well-known mines of the district is being developed again after several years of idleness, it is reported that some good ore has been uncovered.—The Brian Boru is shipping a steady output of carbonate of zinc from a large vein outcropping at the surface.—Lessees are preparing to resume operations on the Doris where some good carbonate was found last fall.—Owners of the Gipsy Carbonate are about ready to start development again.—It is stated that Denver people are inspecting the Ilex and surrounding ground, proposing to undertake a large drainage enterprise similar to those just completed in other parts of Leadville.

The Derry Ranch Gold Dredging Co.'s boat, operating in Box creek, is having a remarkable success. Weekly clean-ups are being made, and although the exact value of the gold has not been made public, the manager states that it is profitable. This year's results are reported to be better than those of last year. Leadville people traveled over this deposit for years without suspecting its value.

Denver people are preparing to do some extensive diamond-drilling in Prospect mountain, close to the Valley adit, where ore has recently been opened. The entire area on the mountain from the Valley and Omega group, north to the Anderson adit ground near Birdseye on the northern slope, and west to the Mansfield group, covering several square miles, has been staked out by pioneer Leadville mining men who have made their fortunes here and are now residing in Denver. This entire territory will be patented and extensive development done in the near future.

JOPLIN, MISSOURI

THE MISSOURI-KANSAS-OKLAHOMA REGION FOR THE FIRST HALF OF 1915.—MIAMI, OKLAHOMA, DEVELOPMENT.

The first half of 1916 showed total shipments of zinc and lead concentrates aggregating over \$20,000,000 in value, a record over all previous periods. The value in detail was as follows: blende, \$17,085,500; calamine, \$1,919,605; and lead, \$2,503,380. This represents an increase of \$6,955,829 for blende, \$549,641 for calamine, and \$1,405,289 for lead products. These remarkable increases were in part due to increased prices, but also to larger output for the same period. The average price for the first half of 1916 for blende was \$97.38; for calamine, \$70.33, and for lead \$89.58 per ton of 60%, 70%, and 80% products. This compares with \$79.62, \$42.63, and \$51.38 respectively in the same period of 1915. This alone accounts for a large portion of the increase. The increase in price for zinc concentrate is slightly in excess of \$25 per ton, while the increase in the price of lead ore is nearly \$10. Turning to the increase in tonnage, the first half of 1916 produced 175,149 tons of blende, 14,652 tons of calamine, and 27,943 tons of lead. These were gains of 32,000 tons in blende, 3415 in calamine, and 6569 in lead. This does not tell the whole story, as there was stored in bins of ore producers as surplus stocks on June 30, 23,650 tons of zinc ore, compared with 1150 in 1915; and 2000 of lead ore, against 825 tons in 1915. Stocks and increased shipments combined gave a total increase of 35% for zinc and 334% increase in lead. This represents 1810% more than anticipations of the operators at the beginning of the year.

The increase has been a steady growth since the first of

January, and represents the completion of many of the prospecting enterprises undertaken during the latter part of 1915. It also represents in a large measure the revival of many of the low-grade sheet-ground ore mines that had been developed and abandoned during the former period of high prices and reaction in 1907 and 1908. There is yet to come that increase in production which will result from the unusually large number of new producers in the Miami, Oklahoma, district. This field will add a large tonnage to the production during the second half of 1916, and should prices for ores be reduced to a level that would result in the curtailment of production in the sheet-ground district of Webb City, Prosperity, and Duenweg, the increase from Oklahoma alone will probably make up for that decrease by the end of the year. The new mines brought-in from the Oklahoma district belong to that class of producers that can mine profitably when the price is \$10 to \$50 per ton, an advantage not possessed by sheet-ground men.

Development in the Oklahoma field is in many ways one of the most remarkable features in the Joplin district. Starting as an isolated and a small group of prospects developed under adverse conditions, the area has grown fast until it is now one of the richest zinc and lead centres. When first opened, the mines produced concentrate low in zinc and high in iron, bitumen, and silica. These impurities brought the prices paid for the product to a low figure, in some cases as low as \$5 per ton for the finished product; a condition that would have prevented any further development had it continued. With development at deeper levels, however, the amount of iron pyrite decreased, there was no bitumen worth mentioning, and the grade of the concentrate improved equal to that of any other part of the field. With this the advantages of this

centre at once appealed to all mine operators, and the influx of capital, new prospectors, and features of greater importance than in any other mining territory of the centre. No single part of the field ever had the number of prospect drills at work that this one had. Prospecting has been not only extensive, but thorough, and an ore deposit was thoroughly developed before the mill was built, a feature of the work that is entirely different from the former procedure in the older parts of the district. The character of the drilling is different also from that that has formerly been done. Instead of being generally distributed over a lease, the prospector so places the drill-holes that they cross-section the ore-deposit. This has been brought about largely by local experience, of which has shown the deposits to consist of long "runs," the linear dimensions ranging from $\frac{1}{2}$ to $\frac{3}{4}$ of a mile or even greater, while the width of the run would be from 20 to 200 ft. It soon became evident to the prospector that if he put a series of holes across part of such a run that a general distribution of the holes along it would prove of little value. A single cross-section at another point would not only be of

as much value as the general distribution of the holes, but more so in that it gave a chance to determine the width and direction, as well as the thickness of the deposit at a much lower cost. This system of drilling is now generally adopted.

During 1915 there were around 40 drill-rigs constantly at work in the Miami district; during 1916 so far, there have been 150. Naturally such development has shown the existence of a large amount of mineralized ground, and has added a large tonnage to the known reserves at Miami. Following in the wake of the drill-rigs has come the sinking of shafts and the building of mills, so that today the actual tonnage of ore extracted has been largely increased, and the potential production for the remainder of the year will undoubtedly show a much larger increase.

Zinc ore dropped \$5 per ton again last week. Lower prices and a shortage of electric current, due to an accident to the Empire District's Riverton plant, combined to cause a number of large producing mines to shut-down during the week. Most of the sheet-ground producers of West Joplin are down, and several in North Webb City. It is estimated that the production is curtailed at least 1000 tons. There is also less water in the Spring river since the recent rains stopped. It is estimated that concentrate stored totals 7500 tons. In the Oklahoma section the largest surplus is said to be in bins. The output of the Missouri-Kansas-Oklahoma region was 5118 tons of blende, 44 tons of calamine, and 941 tons of lead, averaging \$65, \$45, and \$75 per ton, respectively. The total value was \$405,600.

SUTTER CREEK, CALIFORNIA

ONEIDA AND SOUTH EUREKA.—EUREKA PROGRESS.—CENTRAL EUREKA.

Twenty stamps are dropping at the Oneida mill, one of the plants operated by the South Eureka company, which has 80 stamps crushing on its own mine. An underground hoist is now being installed on the 2200-ft. level of the Oneida shaft for the purpose of sinking a winze and developing that mine deeper than heretofore. The new hoist has a sinking capacity of 1500 ft. The shaft has been unwatered within 400 ft. of the sump, and the block of ground to be opened by this winze and the unwatering of the shaft should yield ample ore to keep the two mills well supplied for some years. The South Eureka company purchased the idle Oneida mine several years ago, the object being to connect the shaft with that of the South Eureka mine, forming a safety exit and improving ventilation. Connections were made, and some ore of good grade opened in making connections, but until recently little work has been done at the Oneida. It was in unwatering the mine below the connecting cross-cut that a shoot of good ore was found that warranted starting 10 stamps of the mill. Now there is no difficulty in keeping 20 stamps supplied. Henry Schmal is superintendent of the combined properties, under general manager H. Malloch. About 250 men are employed.

The old Eureka shaft has been unwatered to a depth of 380 ft. from the surface. Three sinking-pumps are working, and as soon as the shaft is cleared to 600 ft. it is intended to install another pump. Far better progress is being made than was anticipated in re-opening the old shaft, as many of the timbers do not have to be changed. Three shifts of shaft men are employed, and a number of men are engaged on the surface plant.

The sump below the 3200-ft. level of the Central Eureka shaft is being cleaned out, and sinking will be started at once for the purpose of opening at greater depth the good ore mined on the present lowest level. Twenty stamps of the mill are crushing ore from the 2800, 3100, and 3200-ft. levels, and sufficient ore is now available to permit starting another 10 stamps within a few days. W. J. Bryant has been appointed foreman of the mine, taking the place of W. Parrow, who resigned.

GEOLOGICAL SECTION OF NORTH EASTERN OKLAHOMA.

building of new mills became more than in any other mining territory of the centre. No single part of the field ever had the number of prospect drills at work that this one had. Prospecting has been not only extensive, but thorough, and an ore deposit was thoroughly developed before the mill was built, a feature of the work that is entirely different from the former procedure in the older parts of the district. The character of the drilling is different also from that that has formerly been done. Instead of being generally distributed over a lease, the prospector so places the drill-holes that they cross-section the ore-deposit. This has been brought about largely by local experience, of which has shown the deposits to consist of long "runs," the linear dimensions ranging from $\frac{1}{2}$ to $\frac{3}{4}$ of a mile or even greater, while the width of the run would be from 20 to 200 ft. It soon became evident to the prospector that if he put a series of holes across part of such a run that a general distribution of the holes along it would prove of little value. A single cross-section at another point would not only be of

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

JUNEAU

Progress at the Alaska Juneau property is as follows: Steel frame for the coarse-crushing plant is completed, and the sides and roof are being put on. Power-house frame is half finished. Sixty per cent of the mill-building foundations are made. Some machinery for the crushing and power plants has arrived. The crushers will be two No. 9 gyratory and two 36 by 48-in. jaw type. Two generators are to be 6000 kw. each.

According to B. L. Thane of the Alaska Gastineau, on June 26 the mill treated 5700 tons of ore. Since the beginning of the operation of the big mill, the average cost of mining and milling the ore has been considerably under the 75c. per ton, which was the original estimate made by the engineers. Eminent men of the mining profession freely predicted that the costs could not be reduced to 75c. as estimated. For the past few months the costs have been 65c. and under. The mill is at present being operated at a 6000-ton average daily capacity, which was the original estimate, but its actual capacity is more than double that amount, or between 12,000 and 15,000 tons daily. As the mine development to the east progresses the mill will gradually be speeded up. Owing to the contour of the ground and the lay of the orebody on the west end, the ore must be taken from certain places first in order that the mine's producing capacity be not impaired. This work is now progressing rapidly and large bodies of ore of a higher value are being opened out for stoping purposes, and within a short time the mill will be at capacity as the company is able to take the ore from the east end and mix it with the west end ore, bringing the average of the ore to the correct grade.

ARIZONA

GILA COUNTY

The Inspiration Needles company at Miami has two drills in operation and will shortly start three more. No. 1 was down 125 ft. on July 17 and is making from 20 to 30 ft. daily. Over 30 men are employed.

MOHAVE COUNTY

A Marcy ball-mill has arrived at the United Eastern mine at Oatman. The new 200-ton plant includes this, tube-mills, Dorr classifiers, thickeners, etc., and Merrill precipitating presses.

The Arizona Corporation Commission has ordered the Tom Reed company to resume supplying citizens of Oatman with water. The company also sells electric current in the town. To further help the water supply the Oatman Water & Sewer Co. has been formed, and has purchased the water of the Big Jim mine, the Mazona supply and plant, and the supply and plant of the Lexington-Arizona Mining Co., which furnishes the town of Old Trails. The pipe-line of the Orion Mining Co. has been purchased. In turn, the new company will furnish water to the Orion and it will start its stamp-mill and do custom work. The Oatman water company will also pump water from wells along the Colorado river, a distance of 11 miles, as has been previously mentioned in these pages.

Owing to a wage dispute miners and mill-men at the Gold Road are on strike, affecting about 70 men. Recognition of the Snowball Miners' Union No. 124 is part of the grievance. The strike lasted 5 days, demands being granted temporarily.

For violation of the 8-hour law, allowing men to work over-

time, the manager and superintendent, two contractors, and the Pioneer company are being tried at Oatman, at the instance of the Snowball Miners' Union.

YAVAPAI COUNTY

According to J. Nelson Nevius in the *Bulletin* of the Chamber of Mines and Oil of Los Angeles, the Octave gold mine, 10 miles east of Congress Junction, in the Walker district, will shortly be a producer again. Past yields to a depth of 2000 ft. have been \$2,000,000. After erecting an expensive electric power-plant at Wickenburg, a 12-mile transmission-line, and a complete motor equipment at the mine, the property was shut-down some years ago. The vein has recently been opened beyond the fault for 270 ft., averaging 27 in. wide and \$10.00 per ton. The shoot is poor for 25 ft., followed by 90 ft. of \$12.44 ore across 4 ft. H. C. Gibbs of Boston is president of the company.

ARKANSAS

SEBASTIAN COUNTY

On July 15 the Fort Smith Spelter Co. at Fort Smith produced its first metal. Two blocks of retorts are reducing ore, others to follow at an early date.

CALIFORNIA

AMADOR COUNTY

The 40-ft. high and 500-ft. long tailing-dam of the Argonaut company has been completed at a cost of \$25,000.—The Kennedy company is to increase the height of its concrete dam by 20 feet.

INYO COUNTY

According to L. D. Gordon, general manager of the Cerro Gordo Mines Co., near Keeler, the largest body of zinc ore ever opened in the property was encountered last month on the 200-ft. level, 500 ft. south-east of the shaft. It is zinc carbonate that occurs as a replacement in limestone. It is circular in form, standing vertically, and is 25 ft. diam. A square-set slope is being carried up above the 200-ft. level, and there is a winze down 40 ft. below the 200-ft. level all in ore. It contains 35% zinc. Monthly shipments are 700 tons of ore and 1500 tons of old slag.

NIADADA COUNTY

(Special Correspondence.) A 5-ft. vein of copper-gold ore has been discovered at a depth of 35 ft. on the Downey ranch, 12 miles below Grass Valley. The ore is said to assay 5% copper and \$7.50 gold per ton. Development is proceeding under the management of W. R. Biddle.

Shipments of high-grade chrome ore are being made from the Red Ledge mine in the Washington district. The chrome is found in small decuss in a gold-bearing formation. Development of the 6-ft. vein of gold ore recently opened is proceeding vigorously, and a good quantity is going to the mill. Streaks of specimen ore are found with the milling quartz. The Red Ledge is owned by Col. & William on of Washington Grass Valley, July 16.

PLUMAS COUNTY

The Utah Construction Co. of Salt Lake City has been awarded the contract to build 27 miles of railway from the Engels copper mine in Lights canyon to Keddle on the Western Pacific at a cost of \$800,000.

At the Walker copper mine the adit has been driven into the lode for 20 ft., and is now almost under the shaft. The aerial tram is now delivering ore to the bins of the new mill, which will be finished in three weeks.

SHASTA COUNTY

Miners of the Mammoth Copper Co. are demanding an increase of 50c. per day in wages. Present wage is \$3.50 to \$3.75, plus 25c. when copper is above 26c. per lb. The bonus was not paid in June, owing to low copper. The men want straight pay and no bonus. The company has since agreed to the men's demands while copper is over 15 cents.

SIERRA COUNTY

Around Sierra City there is reported to be considerable work going on. On the west slope of Sierra Butte (8600 ft. high) is the Monarch mine supplying ore for 20 stamps.—Development in the Cleveland is expected to give good results; 25 men are employed.—An Oakland syndicate has secured a bond on the Bullion claims from F. J. Cook and others.—The Bigelow is under bond to W. B. Pearson of the Plumbago mine, near Alleghany.—Under the management of F. E. Barnett the Butte Saddle and Sacred Mound mines are being opened.—Good ore has been opened in the Chipps mine, which has 10 stamps.—The William Tell and Sierra Butte properties are practically idle.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—The Colorado Central Leasing Co., operating the Colorado Central-Alhunde group of mines on Leavenworth mountain above Georgetown, will shortly start work in the construction of a 100-ton concentrating plant. It is proposed to treat all dumps of the mine, as well as extract numerous old stops. A steam tramway 3 miles long is to be constructed. T. Kyner is manager.—The Linn mill, which has been closed for the last two weeks undergoing repairs, will resume next week. A 48% lead concentrate is being made.—Work has been resumed on the Rendahl property on Bard creek and early shipments are promised.—A shipment of 200 tons of silver-lead ore will be started next week from the Wide West mine on Leavenworth mountain. This ore is of good grade, and will yield close to 100 oz. of silver per ton. A. L. Stephens is manager.—Work has been resumed on the Aramosa mine on Columbia mountain by A. Swanson & Co. Drilling is in progress on a 6-in. streak of silver-lead that is worth nearly \$100 per ton.—The Culley adit on Saxon mountain is being repaired preparatory to resumption of work in the face. The bore now has a length of 1100 ft.—Men are employed at the Dorie adit. Numerous caves that occurred during the eight years the property lay dormant are being caught up and extension of the adit will be in order within 30 days. It is proposed to drive 1200 ft., when cross-cutting will start to the west to connect with the Capital adit workings. T. Kyner is manager.—The Tol Reynolds property on Alpine mountain is receiving attention and occasional shipments of a lead-zinc ore are going out. The ore is consigned to the Linn mill for separation. L. B. Davenport is lessee.—The Capital Tunnel & Mining Co., controlling one of the largest mineral estates on Griffith mountain, has awarded a contract to John Connors to extend the west drift 500 ft. This will take the heading to the end-lines of the Aetna vein.—Hamilton & Co., leasing on the west drift of the Aetna vein, has a 4-ft. vein of smelting ore exposed that brings a settlement averaging \$70 per ton in gold, silver, and lead. A net earning of \$2000 per month is made.—Work has been resumed on the Queen City group of claims on Democrat mountain. Repairs are being made preparatory to extending the adit, which now has a length of 600 ft. G. W. Twagarden is manager.—The Red Oak Mining Co. has been prosecuting active development for the last several weeks.

Operations are being centred through the Sceptre adit, and there is already a fine show of ore. E. Anderson, of Georgetown, is manager.—Stephens brothers have secured a favorable lease on the greater portion of the Pelican mine, and are now employing men in repairing the various workings. It is proposed to send a large tonnage of lead-zinc ore to the Mendota mill.—It is reported that work will be resumed at an early date on the Kelly adit on Democrat mountain. This bore has a length of 2800 ft. A working fund of \$12,000 has been provided.—The Argo Leasing Co., operating the Doctor Town mine in the Daily district, will shortly start work in the construction of a mill with a daily capacity of 50 tons. The road leading from Empire station to the mines is now being repaired so that heavy machinery may be transported. Albert Hanson, of Empire, is manager.

Idaho Springs, July 18.

DOLORES COUNTY

After spending \$250,000 on development and \$75,000 on a mill, etc., also paying off a bond of \$150,000, the Rico Wellington Mines Co. is out of debt. Over \$15,000 of ore is in transit. A compressor and drills are to be installed. J. C. Jensen is manager at Rico.—The Rico Argentine Mining Co., under the same management, is to install similar machinery.

LAKE COUNTY (LEADVILLE)

When pumps arrive the La Plata mine in California gulch is to be unwatered.

Exploration in East Tennessee gulch is receiving attention. The Helen Gould adit is in over 600 ft. in good porphyry, and has opened a small vein assaying 1½ oz. gold and 22 oz. silver per ton. The Jennie June, Emma Mabel, and Gold Leaf are properties of promise.

Large shoots of zinc carbonate and sulphide have been opened in the Gambetta on Yankee hill. The monthly output of these ores is 800 and 400 tons, respectively.

SAGUACHE COUNTY

(Special Correspondence.)—Near the San Luis lakes, east of Hooper, the San Luis Soda Co. is to treat the extensive deposit of soda owned by it.—A large deposit of manganese ore has been developed by a company 14 miles east of Moffat. S. R. Miller, of Moffat, is president.—On Pole creek, near Liberty, the Golden Treasure Mining Co. is developing by adit a good gold-copper vein. Machinery is to be ordered. B. O. Roloson is manager.—Since the Rolla mine at Bonanza was sold that place is much more active than before.

Crestone, July 14.

SAN MIGUEL COUNTY

In May the Tomboy company treated 13,000 tons of ore for bullion worth \$94,000. The profit was \$28,650.

MICHIGAN

THE COPPER COUNTRY

The Calumet & Hecla reports the June outputs as follows, in pounds:

Mines	June	6 Months
Ahmeek	2,280,923	11,461,195
Alhonz	922,584	5,137,907
Calumet & Hecla	7,217,837	38,157,582
Centennial	216,919	1,269,637
Isle Royale	1,138,814	6,035,766
La Salle	69,370	632,608
Osceola	1,571,714	9,791,439
Superior	286,124	1,758,465
Tamarack	515,321	3,416,425
White Pine	302,448	2,190,472

On July 15 the Calumet & Hecla Mining Co. celebrated its fiftieth anniversary at Houghton. Everything went off well, save for a little rain which interfered somewhat. The affair

was held in Calumet park. The crowd was addressed by the general manager, James MacNaughton; Henry L. Higginson of Boston, long connected with the company; and Governor Ferris of Michigan. The parade of employees, with Mr. MacNaughton as grand marshal, consisted of 5600 men. At 2 p.m. the honor medals were distributed, after some remarks made by Rodolphe Agassiz. There were 169 gold, 38 silver, and 822 bronze medals to men who had worked over 40, 30, and 20 years, respectively, for the company.

During May the Copper Range Railroad's revenue was \$90,639, of which \$21,647 was profit. In 11 months the revenue totaled \$811,970, against \$603,094 in the previous term. The respective profits were \$146,161 and \$73,420.

MONTANA

PHILLIPS COUNTY

Fire destroyed property in the mining town of Zortman, in the Little Rockies, to the value of \$25,000 on July 8.

SANDERS COUNTY

Thirty tons of antimony ore was shipped by F. S. Houghland and partners from Thompson Falls last week. They have a good property on Prospect creek, midway between Thompson Falls and Murray.

SILVERBOW COUNTY (BUTTE)

The Trail, Grand Forks, and Greenwood smelters in British Columbia are to smelt 500, 50, and 100 tons daily, respectively, from the Bullwhacker copper mine. The smelting charges are \$3.50, \$3, and \$4 per ton, with \$4 per ton for freight from Butte. Lessees last week shipped a car of 12% ore to the East Butte smelter.

Work has been suspended temporarily at the Rainbow mine, whose shaft is down 1500 ft. The company is developing the Butte & London.

No. 2 adit of the Butte-Columbia company, at the head of Tramway gulch, is in 800 ft., and is within 175 ft. of the lode.

Electric motors, cells, insulators, anodes, and other apparatus of the Butte-Duluth was sold last week by trustees order for \$6174.

NEVADA

CLARK COUNTY (GOODSPRINGS)

According to T. H. M. Cranpton, copper minerals are more abundant in the Goodsprings district than generally supposed. They are found with certain zinc deposits, alone, with iron, and with platinum. The Green Monster has copper-lead-zinc ore, the Copper Peak copper carbonates alone, cuprite alone in the Columbia, and malachite and brochantite in the Boss platinum mine.

ELKO COUNTY

In the northern part of this county, 8 miles south of the Willow Creek dam, W. C. Davis and Salt Lake City people have opened a deposit of rich cinnabar over a length of 140 ft., and 12 ft. depth. A 10-ton plant is to be erected.

At Jarbidge the Long Hike and O. K. mines are bonded to the Sloss interests of San Francisco, while the Success and Pick and Shovel properties are bonded to the Tevis people. The Buster mine is also the subject of a deal.

HUMBOLDT COUNTY

For the Oklahoma Gold Mining Co.'s mill out from Jungo on the Western Pacific line, 30 miles south-west of Winnemucca, lumber and machinery has been bought in San Francisco. T. Ewing is president.

The Bird winze in the Seven Troughs Coalition is down to the 1725-ft. point in rich ore.

Native silver is being mined in ore from the deep workings of the Rochester Mines Co. Winze 301, known as the Codd winze, now down a trifle over 800 ft. on the dip of the east vein, produces this ore. The whole bottom of the winze is in

ore of much better than average milling value, latest assays returning over \$10 gold and 25 oz. silver per ton. The Codd winze is being sunk rapidly to connect with the raise from the Friedman adit. It will eventually be the outlet for ore from all parts of the mine.

LINCOLN COUNTY

The Consolidated Nevada-Utah company's new mill near Pioche is working to capacity, producing 500 tons of 60% zinc concentrate, and 50 tons of iron-gold-silver-lead concentrate per month.

LYON COUNTY

A dredge is to be erected at Dayton by the Rae Consolidated Gold Dredging Co. J. B. Rae is president. The E. R. Bacon Machinery Co. of Los Angeles is to supply some of the plant.

NYE COUNTY (TONOPAH)

During the second week of July, Tonopah mines produced 10,360 tons of ore valued at \$212,560; in the third week the yield was 10,139 tons worth \$208,582.

The June output of the Belmont was 230,652 oz. of silver and 2400 oz. of gold, from 12,074 tons of ore. The profit was \$116,847. The returns for 6 months total 15,344 oz. of gold and 1,448,905 oz. of silver from 75,516 tons of ore. Profits amount to \$649,673.

For June the Tonopah Mining Co. reports 9060 tons treated, 119,325 oz. of bullion shipped, and \$19,950 net profit. Work is to be extended at the Sand Grass claims, as the 70-ft. head-frame at the Red Plume shaft is to be moved there.

The Jim Butler company has decided to appeal against the recent decision in its suit with the West End, wherein the latter had a favorable judgment.

At 1260 ft. in the Extension the junction of the North Merger and Murray veins has been reached. This makes the former shoot 700 ft. long, and from 3 to 30 ft. wide.

STOREY COUNTY

The United Comstock Pumping Association has commenced to unwater the north end workings to the 2900-ft. level, under water since 1885. This will re-open 200 ft. more ground. Unwatering from 2500 to 2700 ft. cost \$17,000; the proposed work will cost less. The Union shaft will be completed to 2700 ft in a few days.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence.)—Merchants and business men of Clifton, Arizona, are making a strong bid for the Mogollon

MAP SHOWING LOCATION OF THE MOGOLLON DISTRICT, WITH REGARD TO ITS TRANSPORT PROBLEMS.

business. It is said that from a survey down the El Paso river good road grades have been found. This route would give a haul to railroad of about 65 miles instead of over 80 miles via Silver City, New Mexico, and would reduce freight charges in the neighborhood of \$5 per ton.

Work is to be started by the Alberta Mining & Development Co., A. H. G. Palmer in charge, at the Alberta claims, which are favorably situated.

The Eberle mine shaft of the Oaks Co. has been unwatered. Drifts at the bottom are yielding ore for the custom mill.

The Pacific mine shaft has been re-timbered to 500 ft. Everything is electrically driven.

Abundant rains in the mountains during the past week have assured ample water supply for mines and mills, and all plants are running at full capacity. The economic importance of utilizing one of the locally available sites for a hydro-electric installation is becoming more and more apparent, and it is confidently believed some definite steps to this end will be taken in the early future on a scale sufficiently large to meet the growing power consumption of the district.

Mogollon, July 18.

GRANT COUNTY

A recent addition to the geologic map of the United States which the U. S. Geological Survey is constructing is the Silver City folio, by Sidney Paige, which describes the geology and resources of the region adjacent to Silver City, in southwestern New Mexico. It contains geologic and topographic maps and a map showing geologic structure, besides numerous photographic illustrations. The country described has long been known for its deposits of gold, silver, copper, zinc, and iron, all of which are mined. The Silver City district borders the desert region north of Deming. It is partly mountainous, partly a foot-hills country, and its geology is complex and varied. Sedimentary and igneous rocks furnish a long record of its history, in which volcanism, faulting, and folding each played a part. In recent years the development of valuable bodies of low-grade porphyry copper have added to the fame of the Santa Rita or Chino district, in the Silver City region, where for more than a century rich oxide ores of copper have yielded great returns. In the Burro mountains also deposits of low-grade copper ore are developed, and zinc mining has been stimulated by the development of replacement deposits near Pinos Altos. Turquoise, of superior quality and in extremely rich deposits, has in the past been produced in this region.

OREGON

JOSEPHINE COUNTY

The well-known Layton placer property on upper Williams creek, near Grants Pass, has been sold to the Pacific Placer Co., headed by Austin Wilson of Boston, by the heirs of the late J. T. Layton. To the 600 acres are to be added the adjoining 400 acres. There are 38 miles of ditches, delivering water with a 300-ft. head to the giants. More plant is to be added.

UTAH

BEAVER COUNTY

A 25-ton flotation plant is proposed for the Antelope Star lead mine, 12 miles from Milford. A. C. Nebeker is manager.

At the Moscow mine the shaft is down 1000 ft. During June 200 tons of copper ore was shipped to smelters, averaging 5% metal.

At a depth of 155 ft. in the Croff mine, in the Lincoln district, 8 ft. of ore assaying 49c. gold, 11.2 oz. silver, 0.27% copper, 30.2% zinc, and 21% lead, has been cut. R. R. Tanner is manager.

JUAB COUNTY

A 25-ton zinc leaching plant is to be erected at the Lower Mammoth mine at Tintic. The process of Pierre Penarot will be used. The Western Smelter Co. of Salt Lake City controls the system, and may construct the plant at Goodsprings, Nevada.

In sinking the new shaft at the Chief Consolidated, progress in the first few days was 10 ft. daily.

Profits of the Eagle & Blue Bell are increasing so much that it is thought dividends may soon be resumed.

SALT LAKE COUNTY

The Bingham-Tooele tunnel of the Utah Metal & Tunnel Co. is in 853 ft., following a porphyry dike to the limestone-quartzite contact.

The Alta Tunnel & Transportation Co.'s tunnel in Big Cottonwood is in over 2000 ft. Gas from blasting is bad, but a suction-fan has been installed at the portal to draw-off the fume.

Preliminary work for power-plant, etc., at the Wasatch in Little Cottonwood is completed, and it is expected that driving of the tunnel will be commenced by August 1.

TOOELE COUNTY

At the International smelter at Tooele, two units of the Cottrell process were started last week. This will reduce fume considerably, and several farmers have settled with the company for alleged damages to crop. Two more units will be ready in a month.

The Ophir district is producing more zinc ore than ever before. The Ophir Hill Consolidated is treating 300 tons daily.

UINTAH COUNTY

In the Three States district, close to the Colorado and Wyoming borders, a rich copper property is being developed by a company of which J. T. Fitch is president, and W. O'Neil manager.

WASHINGTON

STEVENS COUNTY

The Electric Point Mining Co. near Northport closed a contract with the Trail, B. C., smelter for its entire output for one

NORTH-EAST WASHINGTON.

year, shipments to be made at an average rate of between 75 and 100 tons daily. The clean sulphide ore is to be kept separate as much as possible from the carbonate ore. All ore

containing less than 60% lead in carload lots is to be classed as carbonate, and take the lower freight and treatment rate provided by the contract.—The Kusa Spelter Co., with zinc smelters at Kusa, and Dewar, Oklahoma, and Donora, Pennsylvania, has secured a contract for one year on the whole zinc carbonate output of the Norman Mines Co., which is operating the Great Western and Last Chance mines, near Northport, and also has contracted for the product of the Jackson Basin Zinc Mines Co., operating several properties in the Kaslo-Slocan district of British Columbia, according to Newton W. Emmons, north-western representative of the Kusa company.

According to James A. Welch, president, the Norman Mines Co., operating the Last Chance and Great Western groups, six miles from Northport, will construct a mill this fall to handle the lower-grade ores from both properties. It is also announced that the company has just entered into a contract with the Ozark Smelting & Mining Co. at Coffeyville, Kansas, by which it will forward 1000 tons of lead zinc ore at a net profit of \$22.50 per ton. This ore is now being loaded at Northport and the consignment will be out before the end of August.

The outlook for practically all the companies, both development and operating, in the Chewelah district, is decidedly promising, and within the next year there undoubtedly will be a number of new shipping properties added to the list. Lack of capital to properly finance development and exploration is all that has prevented the camp from becoming recognized as one of the important copper regions of the West, but this difficulty gradually is being overcome, and nearly all the interests represented there have funds to carry their plans to a successful conclusion. The United Copper is shipping concentrate regularly. The Copper King is soon to commence ore extraction. The Security Copper shaft is down 350 ft. Prospects at the Chewelah Consolidated, Lookout, and Jumbo-Echo are said to be good.

MEXICO

An announcement made last week by the International Commission Co.'s customs department at Douglas dealt with a list of the duties fixed by the Mexican government for the exportation of various metals in the month of July. All duties are estimated in Mexican national gold. The unit of assessment is the kilogram of 2.2 pounds:

Silver bars, \$3.353 per kilo; concentrates and ores, \$4.191.

Copper bars, \$0.05712; concentrates and ores, \$0.07175; copper sheets, \$0.05455.

Lead bars, \$0.00905; concentrates and ores, \$0.01131.

Antimony bars, \$0.00454; concentrates and ores, \$0.00639.

Tungsten metal, \$0.27949; concentrates, \$0.34936.

Graphite, \$0.00166; refined, \$0.02229.

Zinc bars, \$0.07271; concentrates and ores, \$0.09098.

Tin bars, \$0.01898; concentrates and ores, \$0.02512.

Obituary

PHILIP DEBENHEIMER, who first introduced the 'square set' system of timbering into American mines, died in this city on July 20 at the age of 84. In 1860, when a vein of ore 65 ft. wide had been exposed in the Ophir mine, on the Comstock, he went from Georgetown, California, to Virginia City, Nevada, at the request of W. F. Babcock in order to overcome the difficulties of stoping ore of unusual width. He introduced what is now known everywhere as the square set, but he obtained no particular reward for his ingenuity and although respected and liked by the mining community in California he died a poor man. He made the first report on the project to bring water from Lake Tahoe to San Francisco and did much useful work in his day. He is survived by a widow. It is proposed to do honor to his memory by helping her.

PERSONAL

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

S. H. DOLBEAR has gone to New York.

JAMES T. DIXON has gone from London to Colombia.

HUBERT LANG is examining mines between Elko and Ely, Nevada.

F. L. SIZER is examining mines in Santa Cruz county, Arizona.

H. L. SWAIN and H. C. BALDWIN have come to San Francisco from Mexico City.

ALFRED H. BROOKS, of the U. S. Geological Survey, is at Ketchikan, Alaska.

HENNES JENNINGS and H. C. PERKINS are at the Fairmont hotel, San Francisco.

HARRISON A. DUNN, reported to be in prison in Mexico City, is safe at Los Angeles.

ERNEST KLEPETKO, of Anaconda, visited Houghton on his return from New York.

R. S. BURDETTE has left Guadalajara, Mexico, and is temporarily in San Francisco.

FRANK H. PROBERT has gone to Portland, Oregon. On his return he will go to Arizona.

HOWARD D. SMITH sailed from New York by the *Touraine* on July 17, on his way to London.

FREDERICK G. CLAPP of the Associated Geological Engineers is in Wyoming, and will go to Oklahoma shortly.

ROBERT H. JEFFREY has been appointed manager to the Mazapil Copper Co., at Saltillo, Mexico, in succession to the late PERCY E. O. CARR.

C. N. WHITAKER, JR., was married on June 9 to Miss Alice Wishard. He returned recently from Mexico and is now with the Empire Zinc Co., at Denver.

Phelps, Dodge & Co. announces the following promotions: WALTER DOUGLAS to be vice-president with headquarters at New York; S. W. FRECHU succeeds Walter Douglas as general manager; A. V. DYE becomes assistant-general manager; G. H. DOWELL becomes general manager of the Copper Queen Consolidated Mining Company.

LOUIS ROSENFELD, president of the Eagle Shawmut Mining Co., at Shawmut, Tuolumne county, California, died in San Francisco on July 20, at the age of 54. For over 20 years he controlled and operated the mine, one of the best along the Mother Lode, without any litigation. Those who knew him personally and in business spoke highly of his qualities.

JOHN F. CAMPION, mine operator and banker, formerly conspicuous at Leadville, died at Denver on July 17. He was born on Prince Edward island, Canada, on December 17, 1849. In 1862 he went to California with his parents. At the age of 17, toward the end of the Civil War, he enlisted in the Navy and made a good record. At the end of the War, he returned to California and started his mining career. Later he moved to Nevada and then to Leadville in 1879, the boom year. His work at Leadville was most useful. Besides being a pioneer he had enough knowledge of geology to undertake successful exploratory work. He is survived by his wife, four children, and a brother in Denver.

The U. S. Civil Service Commission announces an open competitive examination for laboratory assistant, on August 23-24. From the register of eligibles resulting from this examination, certification will be made to fill existing vacancies in the Bureau of Standards, at entrance salaries ranging from \$900 to \$1200. Applications should be filed at Washington as early as possible.

THE METAL MARKET

METAL PRICES

San Francisco, July 25.

Antimony, cents per pound.....	15
Electrolytic copper, cents per pound.....	27.50
Pig lead, cents per pound.....	7.00—7.75
Platinum: soft metal, per ounce.....	\$65
Platinum: hard metal, 10% iridium, per ounce.....	\$69
Quicksilver: per flask of 75 lb.....	\$80
Spelter, cents per pound.....	12
Tin, cents per pound.....	41
Zinc-dust, cents per pound.....	20

ONE PRICES

San Francisco, July 25.

Antimony: 50% product, per unit (1% or 20 lb.).....	\$1.00
Chrome: 40% and over, f.o.b. cars California, per ton.....	12.00—16.00
Manganese: 50% product, f.o.b. cars California, ton.....	12.00—20.00
Magnetite: crude, per ton.....	7.00—9.00
Molybdenum: 50% and over, per pound.....	0.60—1.15
Tungsten: 60% WO ₃ per unit.....	25.00

New York, July 19.

Antimony: The decline in the price of refined metal seems to have put a quietus on business in ore. At prevailing prices it seems impossible to import the ore from South America. No quotations are given.

Tungsten: Dealers report the market difficult to gauge, the smaller buyers being ready to pay higher prices than the large consumers. Business in 20-ton lots has been done at \$27 per unit, while \$25 has been bid for a 25-ton lot. France is reported in the market for tungsten ores at about \$20 per unit, and wants a large quantity.

EASTERN METAL MARKET

(By wire from New York.)

July 25.—Copper is quiet though stronger; lead is dull, prices are nominal; spelter is stronger abroad, sellers are reserved.

COPPER

Prices of electrolytic in New York, in cents per pound.

Writing at the end of June, Samuel Montagu & Co. of London

states that the cessation of China sales created a firm tone, resulting in a rise. After certain Indian Bazaar operators had taken profits on re-sales during the early part of the period under review, the improved outlook of the market encouraged other Indian dealers to make moderate purchases on speculative account. Thus a measure of competition with coinage orders arose and a more robust tone was the outcome.

Domestic consumption is increasing considerably, especially in photography. The Eastman Kodak and International Silver use 4,000,000 and 3,000,000 oz. yearly, respectively.

It is estimated that Mexico's silver production has dropped to the rate of 25,000,000 oz. per annum, about 35% of normal. It is said that Mexicans are hoarding silver, rejecting the new Carranza currency. Mining companies report that each month 25% of wages disappears from circulation.

Tin is quiet at 38.50 cents.

Eastern Metal Market

New York, July 19.

ZINC

Zinc is the one metal that shows any betterment with regard to buying or prices. Galvanizers have taken a good quantity for shipment throughout the year, and the quotation is a little stronger.

Copper continues practically lifeless, and concessions are greater, with some reported on the part of producers.

Lead is dull and weak.

Tin is getting low enough to interest consumers, despite the fact that most of them are well covered.

Antimony is stagnant.

Aluminum is unchanged at 59 to 61 cents.

It is not a bad thing that the metals are approaching a more rational basis with regard to prices. Even at below present levels, big profits are possible, and with costs nearer normal a large amount of domestic business is likely to be released, as exemplified by zinc. Many prominent members of the trade are frank in saying that excessive war prices are not healthy.

Slight shading of prices is beginning to appear in some steel products which have been so high as to repress domestic demand, this being particularly true in the case of structural shapes. Jobbers in this field have led the way by under-selling the mills. Export sales continue to grow in magnitude. Foreign consumers are contracting for shell-steel, beams, steel rails, plates, steel-making pig iron, barbed-wire, spikes, steel axles, etc., all of which will have a supporting effect on the market. The lower cost of zinc is having its effect in galvanized-steel products, galvanized sheets having sold down to 4.25 cents.

There is a vast amount of second-hand metal-working machinery on the market, and tool builders are wondering what effect its existence will have on their future business.

COPPER

The market continues practically lifeless, but with second-hand offering substantial concessions there should come a change before long. It already is reported that certain producers are looking for business, and that they are willing to take prices lower than those for which they have been holding, although they are not yet willing to meet re-sale prices. On the other hand, it still is insisted that they have contracts aplenty to keep them busy until September, at least. The situation is so mixed that it seems the forerunner of a change of some kind. Electrolytic can be had easily at 25c. for prompt delivery, and probably at 1c. less, while forward deliveries are quoted at 23.50 to 24c. The War contractors and large consumers are unquestionably well covered for this quarter. A little review of some of the products into which copper enters may be interesting: The brass mills would like to have more demand for the larger sizes of brass rods for which they ask 29c., or less, per lb. Sizes under $\frac{1}{4}$ in. are still held at a premium. Sheet brass is as hard to procure as it has been since the War started, the mills having orders booked, which, in conjunction with the known requirements of their regular customers, will keep them busy for some months to come. High sheet brass is quoted at 38 to 39c. Brass wire is not as difficult to obtain as sheets, and is quoted at 38 to 42c., delivery in three to four months. The mills which make brass and copper tubing are loaded up, seamless copper and brass tubing being quoted at about 44c. Hot-rolled sheet copper is 37.50c., and cold-rolled, 38.50c. The London market for electrolytic is weak, and since the last report has declined 95 European statistics received here this week show that stocks in Great Britain and France remain about stationary. On July 15 they totaled 7464 tons, against 7603 tons June 30, and 6459 tons, June 15. A slight decrease will be noted. Exports, July 1 to 18, totaled 15,235 tons.

This is the one metal that has shown activity, and an improvement in price. Late last week, with the spot market at about 9c., and some rumors of concessions slightly below this level, galvanizers who for some time had been watching the market closely became active, and they are reported to have taken a good tonnage for delivery to the end of the year. The movement might have been of greater proportions had it not been for the unwillingness of a goodly number of the producers to sell into the future. The buying began at a shade under 9c. New York for spot, and 8.75c. St. Louis, but prices quickly stiffened and mounted to about 9.25c. New York, by July 15. September was taken at around 9c., St. Louis, and October at 7.75c. Consumers had been vainly hoping that futures would drop to 7c. The spot quotation yesterday was about 9.25c., New York, and 9c., St. Louis, and the buying had not entirely ceased. August was quoted yesterday at 9c. St. Louis, and September at 8.75c. The brass mills have not been active as buyers. The price of sheet zinc is unchanged at 15c. f.o.b. smelter, in carload lots. The London quotation for spot zinc is stronger at 41s. an advance of 4d. in the week. Exports in 18 days were 4497 tons.

LEAD

A few thousand tons of lead have been sold for export, but the domestic demand has continued quiet, and prices are sagging. The A. S. & R. Co. has adhered to 6.50c. New York, and 6.42 $\frac{1}{2}$ c. St. Louis, but announcement of a reduction in its prices is expected at any time. Quotations of independent producers and re-sellers have declined steadily, and they undoubtedly have taken what little business has been doing. Their quotation yesterday was 6.25c. New York, and 6.10c. St. Louis. There is no new war demand, and features are few, but one which may be mentioned is a railroad strike in Spain which may make deliveries from that country somewhat difficult. If the strike is serious it may cause some of the warring nations to look here for lead. Meanwhile the market is a waiting one, consumers expecting to see lower prices. The London quotation for spot lead is practically unchanged since the last report, namely, £28 10s. Exports from the 1st to 18th amounted to 2046 tons.

TIN

Heavy arrivals and the well-supplied condition of the consumers have conspired to make a quiet market, with consequent lower prices. Whereas a week ago spot Straits tin was quoted at 38.50c., it was to be had yesterday at 37.25c. Banca can be had at a fraction of a cent less. At present price levels, consumers are showing interest and it would not be surprising if a buying movement of moderate size should come. While most of the consumers are well supplied, there always are those who will buy at a bargain and in the case of tin, it also is to be considered that its consumption is on a record-breaking basis. Never before, perhaps, have the tin plate mills been so busy. Not only is the domestic demand good, but export sales at premiums are numerous. The arrivals of pig tin this month aggregate 1580 tons, and there is about 2100 tons. The spot Straits quotation at London yesterday was £161 10s., against £169 15s. a week ago, indicating weakness.

ANTIMONY

All that can be said about this metal is that it seems to hold no interest for buyers. Chinese and Japanese grades were quoted yesterday at 11c. duty paid, and at 11 to 11.50c. in bond. One good sale is recorded, a Canadian nonferrous maker having taken a round lot, but the quantity was not sufficient to halt the trend of the market.

Chart for Computing Excavations

The accompanying chart, which is taken from the *Excavating Engineer*, will be found useful in computing the approximate volume of excavations with vertical sides, and can also be adapted to computations for sloping sides. The lines on the chart show the method of computing the volume of an ex-

CHART FOR COMPUTING EXCAVATIONS.

excavation 10 ft. deep by 40 ft. wide by 100 ft. long. Draw line from point 100 in column A to point 40 in column D and mark the intersection with column B. From this point draw line to point 10 on column C. At the intersection with column C read 1500 cu. yd., the volume of the excavation.

Where two dimensions are alike, the work is still simpler. If the excavation is 40 by 40 by 100 ft., it is only necessary to draw the line from 100 on column A to 40 on column D and read the quantity, 6000 cu. yd., directly from column C.

For a cut 100 ft. long, 40 ft. wide at the bottom, 60 ft. at the top, and 10 ft. deep, proceed as for a cut with vertical sides 50 ft. wide.

CRUDE GYPSUM mined in the United States during 1915 totaled 2,447,541 tons. All products totaled \$6,596,893.

BOOK REVIEWS

ANNUAL REPORT of the Board of Regents of the Smithsonian Institution for the year ended June 30, 1915. Charles D. Walcott, secretary. P. 544. Ill., maps, index. Washington, D. C., 1916. May be obtained through this office; price, \$1.50.

As usual, the report of the Secretary and the 22 contributors' papers are of considerable interest and variety. The latter include from astronomy to submarine signalling, primitive life to the linguistic areas of Europe.

LAND AND MARINE DIESEL ENGINES. By Giorgio Supino. P. 309. Ill., plans, index. Charles Griffin & Co., London; J. B. Lippincott Co., Philadelphia, 1915. For sale by the MINING AND SCIENTIFIC PRESS. Price, \$3.75.

This is the third work on Diesel engines that we have received for review in the past few months. The author, an Italian engineer of repute, died in 1913, just as the volume was printed. Translation in English is by A. G. Bremner and James Richardson of London. The Diesel engine is becoming more and more of importance in machine-shops, power-plants, and on vessels. A large number of such motor-driven boats are continually visiting American ports. The trip of the German submarine merchant-boat across the Atlantic was made possible by the Diesel. Part I of this publication discusses Diesels for all services, their fuel, efficiencies, and the like. Part II deals with foundations, bed-plates, engine-framing, cylinders, shafting and rods, valves and gear, reversal of the engine, fuel pump, compressors, marine installations, testing, and rules for classification and survey of Diesels. Interspersed are 370 illustrations and 19 drawings, making the whole of practical value to the modern engineer.

METALLURGY OF STEEL. Metallurgy by F. W. Harbord; mechanical treatment by J. W. Hall. Vol. I, p. 532, ill., charts, plans, index; Vol. II, p. 441, ill., charts, plans, index. Fifth edition. Charles Griffin & Co., London; J. B. Lippincott Co., Philadelphia. For sale by the MINING AND SCIENTIFIC PRESS. Price, \$12.50 for the two books, not sold separately.

There is much excellent material in the 933 pages of reading matter in these two volumes, but space available will permit of only a brief review. Since the last edition there has been no special development in iron and steel manufacture, but steady progress was made in details of practice. These advances are discussed, including the manufacture of nearly chemically pure iron from phosphoric pig-iron in the basic open-hearth furnace, also methods of producing sound ingots and for decreasing segregation. Armor-plate making and theories of hardening steel are brought up to date. The object of the present work is to furnish a full description of the various branches of steel manufacture, both from a metallurgical and an engineering standpoint, as well as to discuss the physics and chemistry of steel in relation to its manufacture. The work has been divided into four sections: namely, manufacture of steel, mechanical treatment of steel, re-heating, and finished steel. The chapters include Bessemerizing, basic furnaces, gas producers, open-hearth furnaces, steel castings, crucible steel, electric smelting, influence of other metals on steel, microscopical examination of metal, plans of typical steel plants, rolling and other mills, power, forging, tube-making, wire drawing, corrosion, and many other important phases of the steel industry. The 571 illustrations are of practical value. American, English, and European practice is compared. Generally the work should be of value to all steel makers. The index of 30 pages by C. O. Bannister is excellent.

EDITORIAL

T. A. RICKARD, Editor

GOLD imports continue at an extraordinary rate. Between January 1, 1915, and July 24, 1916, or slightly over 18 months, the grand total of gold brought into the United States is \$688,877,000, or more than all the gold produced by the mines of the United States from 1909 to 1915. The proper sequel to this is expansion of trade abroad.

BETWEEN August 9 and 12 the Pacific division of the American Association for the Advancement of Science will hold its annual meeting at San Diego. Among the societies included is the Cordilleran Section of the Geological Society of America, as well as the astronomical, entomological, and ecological societies of the Pacific Coast.

FIRES are common during these hot months, endangering mining plants. We regret the bad luck of the Mammoth and Miami communities, where destruction of property has followed upon the ignition so easy when grass and brush are as dry as tinder. In both cases, however, the principal mining equipments escaped destruction. We commend the article on fire insurance by Mr. C. T. Hutchinson, in our issue of June 24, to the attention of mine managers.

TWO YEARS of the pentecost of calamity have passed and the world hopes that the end is in sight. It is estimated that the total cost to all the belligerents is 55 billion dollars. That is the smaller item, the major is the loss of 5,000,000 killed, 5,000,000 crippled, and 5,000,000 imprisoned. Whatever our sympathies, we may unite in hoping that those responsible for this organized calamity will be blighted to all eternity. Those of us who are detached spectators may also join in sympathy and respect for the examples of devotion and self-sacrifice that the nations of Europe have shown to this material civilization.

THE proposed tax on the revenue of the copper companies has aroused protest among those threatened with the unexpected impost. A concerted effort is being made to defeat this selective legislation, largely on the ground that it is unfair to tax copper and not other products, such as cotton, steel, and spelter, which also are used in the manufacture of munitions. It is estimated that the tax would collect \$15,000,000 from the producers of copper and its alloys for the calendar year 1916; and it is calculated that the profit of the industry will be about \$300,000,000 this year. The domestic output of copper is expected to be 800,000 tons, of which

about one-half will be consumed at home. During the 18 months preceding the War, Germany received 240,000 tons of copper from this country. Senator W. A. Clark and other authorities on the subject condemn the tax while they predict a continuation of the heavy demand for copper when peace is declared, anticipating large purchases by Germany and other countries engaged in the work of reconstruction, besides a growing consumption on this side of the Atlantic. We share these anticipations.

Since the above was written we have learned, from Washington, that the Senate Finance Committee has struck the copper tax from the omnibus revenue bill and it is considered probable that the leaders of both houses of Congress will agree to drop the tax, having been convinced that it is unfair.

CONDITIONS in Mexico are unchanged. Señor Carranza talks of resigning, in order that he may present himself for election to the presidency. Any election will be worse than the customary farce while disorder continues to prevail over the larger part of Mexico. The negotiations for a conference proceed in a leisurely way, and it is quite likely that these preliminaries plus the conference and the negotiations to follow may last until the first Tuesday in November has come and gone. Meanwhile Pancho Villa is on the rampage and another party, the Legalista, is hatching a new revolution under cover of Texan hospitality. The publication of the diary of Mrs. Nelson O'Shaughnessy and the letters of Mr. Henry Lane Wilson afford further testimony to the fact that the Mexican political morass has no bottom. As we go to press the speech of acceptance by Mr. Hughes is published. It should please those interested in Mexican affairs. Particularly we like the statement: "It is most unworthy to shrug those who have investments in Mexico in order to escape a condemnation for non-performance of duty."

JIGS constitute a comparatively new addition to the apparatus annexed to a gold dredge, but our readers heard of the innovation about two years ago, when Mr. James W. Neill described the device, which he invented, in our issue of November 28, 1914. Since then the jig has been applied successfully on several dredges. In this issue we publish a description of the device, and the use of it, by a detached observer, Mr. Howard D. Smith, who has taken a good deal of trouble to ascertain the facts. Those with experience in such matters will understand the difficulty of accurate sampling on a dredge and the care necessary to ascertain just what the inter-

position of such a device as a jig is accomplishing. Mr. Frank Griffin, long honorably connected with dredging practice, is responsible for the introduction of the jig at Natoma, and to him Mr. Howard Smith and ourselves are largely indebted for the information now published. We hope that at an early date Mr. Griffin will be in a position to furnish further details.

SPELTER has stopped its retrograde movement, but not before a price of 8 cents had been touched. We agree with our contemporary at New York that this lowest recent price is comparable with the 5-cent quotation of the ante-bellum period in being close to the cost of production. The increased cost, due to higher wages and the advance in the price of materials, has made it hardly more profitable to supply spelter to an 8-cent market than formerly to one that paid 5 cents per pound for the metal. The hurry of production incited by the needs of the munition-makers has tended to decrease the efficiency of labor and to lower the metallurgical extraction. These defects will be overcome in time, perhaps before the present margin of profit is wiped out, but the get-rich-quick phase of spelter production is nearing an end. Meanwhile it is an ill wind that blows no one good; the galvanizing trade is recovering as the price of the metal renders its use profitable for this purpose. For eight months the manufacture of galvanized iron has been crippled by the cost of the chief material, decreasing output by a third. Conditions more nearly normal are at hand apparently.

HARD LUCK has befallen the Tennessee Copper enterprise. When an insistent demand for sulphuric acid was made in the early days of the War, it was expected that this company would be able to take full advantage of the opportunity. Unfortunately a contract running to 1920 had already been made with the International Agricultural Corporation for the delivery of acid at a low price, but the collapse of the cotton market killed the Southern demand for fertilizer and the Agricultural Corporation tried to get out of its obligation to buy the acid. When, however, the price of acid began to soar, in consequence of war-orders, the two companies reversed their positions, the Agricultural Corporation holding to its contract like grim death in the prospect of re-selling the acid that the Tennessee had agreed to deliver. This tangle had been almost forgotten when, on March 21, a fire at Copperhill destroyed the plant in which trinitrotoluol, a powerful explosive, was being made for the Russian government, that Government having advanced \$1,500,000 for the construction of the plant. Whereupon another difference of opinion as to responsibility arose and the Russian government filed suit to recover the money advanced. Still later came the news that the acid-chambers had been closed-down during the spring in order to permit thorough repairs. The mines of this company are in the extreme south-eastern corner of Tennessee near the boundary of Georgia and North Carolina. Suits started by the State of Georgia

over damage to vegetation led to the building of the acid-making plant. During 1915, the Tennessee Copper Co. produced 12,750,148 lb. of copper from pyritic ore yielding 27 pounds of copper per ton. The output of acid last year was 210,666 tons of 60°B., but this rate should be much increased when the new addition to the plant is at work. Over \$5,000,000 in dividends has been paid since 1903. Not so much is heard of the Ducktown Sulphur, Copper & Iron Co., an older English company that operates an acid plant, smelter, and mines in the same district. Their output of copper is about half that of the Tennessee Copper Company.

SHASTA county has been the scene recently of two or three strikes that were settled amicably in short order. It appears that the men employed by the three principal copper-mining companies demanded an increase of 50 cents per day so long as copper sells for 15 cents or better. They preferred this arrangement to bonuses based on a sliding-scale graduated by the price of the metal. It looks as if they had made up their minds that any price much above 15 cents would not be lasting and preferred to lose the chance of a bigger bonus in order to assure themselves of steady wages at a fixed increase. This may prove wise, but we regret the discarding of the sliding-scale, because it involves losing an automatic method of adjusting wages in some sort of proportion to the profits made by the employer. It is easy and pleasant to raise wages in times of prosperity; it is difficult and unpleasant to cut them down when times are bad. That is when trouble begins. However just and reasonable the average miner may be, his leaders have as yet shown too little sense of fair-play to warrant the expectation that a lowering of the wage-scale when copper drops will be effected without friction and opposition. That is why we regret the passing of the sliding-scale at the Shasta mines and smelters.

Engineers and Business

We publish a letter on this subject. It deals with an important phase of professional life. Several public utterances recently have bewailed the narrow horizon of the engineer and his limited scope as a citizen. The suggestion has been made that he is too self-centred, that he thinks parochially instead of imperially on human affairs, that he ought to emerge from his self-made shell and bestir himself as a man and a citizen. With much of this we agree. Perhaps the greater participation in business, as distinguished from technology, and the larger assumption of executive, as against consultative, functions will work to that end. There does not seem much reason for criticizing the engineer in this regard; he appears to be gaining ground in the council-room and on the quarter-deck of enterprise. The names of a number of successful men come to mind as having proved themselves possessed of unusual financial sagacity and executive ability in connection with big enterprises.

Technically educated as they were, they have shown themselves more clever in the counting-room than the ordinary business-man and more skillful in finance than the average banker. An able man generally does not take long to ascertain his highest aptitude and he becomes successful when he has the opportunity to display it effectively. It is at least as true that many engineers make a mess of their careers by mixing in speculation and promotion for which they have no fitness, meanwhile neglecting the purely technical work for which they are peculiarly adapted by inherited quality and special training, as it is that some of them miss the chance to become rich quickly by keeping themselves aloof from the financial side of the industry. No; we need not press the idea of further participation in this essentially tricky and morally dangerous annex to professional life. We prefer to pass to the next suggestion, namely, that the engineer fails to let people know what he can do and thereby misses the chance not only to win clients or employers but to take a larger share of the world's work. That is more urgent. We live in a noisy world, full of assertiveness and pushfulness. The philosophic, which means the wise, man recognizes that to be effective he must adapt himself to the flux of phenomena called life, he must be in harmony with the conditions constituting this complex mode of living we call civilization. To be "a flower born to blush unseen" is a poetic destiny, but it laughs at our notions of virility. Edmund Garrett, one of the great journalists of our time, used to say that two things made life worth while: friends and the hope of being effective. It seems a far cry from so noble an expression to the word 'advertising,' but the fact remains that a man can become effective only by co-operation with his fellow-men, and to get the chance of being so he must become known to them as one whose aid is worth having. Thus we arrive at the idea that the proper study of mankind is man and the cognate idea that the knowledge of men is at least as useful as, if not more useful than, the knowledge of things. We have advised young engineers frequently to become 'acquainted' with the members of their own profession and with the mine-operators, having in mind the notion that such acquaintance would be likely to furnish opportunities for work and employment. Personal acquaintance is a great factor in life and it comes into play in most unexpected ways. Those who read the interviews we have published with the notable men of the profession, and those who will read others that are to follow, will detect how a career can receive a decisive diversion or a fateful direction in consequence of a chance meeting with a forceful personality on a train or steamship. To take the trouble to meet many men means an increase in the chances of meeting one that will be a friend indeed. It is a way of becoming known. There are others. There is the mental acquaintance that follows from the writing of something that many other men will read. Of course, we know scores of instances in which the publication of a sensible article or paper on a technical subject has called attention to a man's—not always a young or hereto-

fore unknown engineer's—ability or capacity in a given direction. We note, for example, with interest, how Mr. E. T. Mellor's recent paper on the geology of the Witwatersrand has been followed so soon by the announcement that he has been appointed consulting geologist to the Rand Mines and Central Mining corporations. We give away no secret when we mention that the preparation of the paper on the surficial signs of copper, by Mr. Frank H. Probert, and the delivery of it on invitation as a series of lectures, let to the offer of the professorship in mining at the University of California; and those of us who belong to the older generation know how the writings on copper smelting by Dr. Edward D. Peters led first to an important and highly remunerative engagement as metallurgical adviser to the Mount Lyell company, and subsequently to the professorship at Harvard, where Dr. Peters has been enabled to find his true *milieu* and fulfill it with rare distinction. Instances could be multiplied. In smaller ways a large number of men, every year, emerge from the rank by writing something that stamps them as intelligent observers or careful experimenters. That, it seems to us, is one of the most effective methods of gaining prominence honorably. We have no patience with those that claim a superior kind of modesty or a sanctified sort of diffidence by abstaining from appearance in print or from taking part in public technical discussions. Usually we have found such mock-modesty a necessary cloak for lack of knowledge or inability to convey ideas, and not the scholar's shyness or the demureness of a scientific intellect. There are those that write too much, and an editor by force of circumstances is one of them, but the number is small. There are those that write to fill space and they are a weariness of the flesh, but they are discovered before their ravages can extend far. We conclude therefore that among the methods whereby an engineer can 'advertise himself,' as it is phrased frankly, or, as we prefer to put it, become known honorably, none is so useful to himself and to others as the occasional writing of an article describing something he has seen or done. When he does it, he shakes hands mentally with a host of new acquaintances among whom presently he will discover several friends.

Directors

The director of an American mining company does not hold a position either of legal responsibility or of financial profit exactly the same as that of the corresponding official in a British company. In England, thanks to the Companies Act, the duties and obligations of the members of a directorate are clearly set forth in great detail, minutely safeguarded by law, and that is why perhaps directors are better paid for their services. An American director does not regard his appointment or election as a matter of gain, because usually the emolument is restricted to a fee of five dollars for attendance at each meeting. Even when as much as \$20 is paid, the

sum is rarely a factor of importance to the individual concerned. In England the fee used to be a guinea, and that is how the term 'guinea-pig' became applied to those who sat on many boards without evincing obvious fitness for their, often self-sought, duties. Now the director in London receives a regular payment, which is almost a salary, ranging from £100 to £200, or even £500, per annum, with £200 to £500, or even £1000, for the chairman. Some men are directors or chairmen of a sufficient number of companies to win a living therefrom, their income from this source running into several thousand pounds per annum. That is one reason why the board usually consists of a small number, generally five or seven, including the chairman. But multiple directorships constitute an absurdity, if not a scandal, there being several gentlemen who are on more than twenty different boards. At £200 apiece that would be equivalent to £4000 or £5000 per annum. The amount of money paid, of course, is not the main point of objection; it is the obvious inability of any man to give proper attention to such a number of enterprises. While a few may make a livelihood out of directing company affairs, it is probable that their presence at the council-table is valuable to them chiefly because it puts them in a position to safeguard the property in which they have placed their own or their friends' money. A smaller number, we regret to add, find it advantageous to be on a board because it enables them to obtain the first information from the mine and use it for profitable share-dealing. In this country boards of directors are much larger, partly because a large directorate is not an expensive luxury and mainly because it is deemed desirable to give representation to divers groups of shareholders. The American Smelting & Refining Company has 30 directors, of whom five belong to the Guggenheim family. The United States Smelting, Refining & Mining Company has 19 directors; the United States Steel Corporation, 18; the American Zinc, Lead & Smelting Company, 15. Undoubtedly the scattered and varied holdings of the big corporations explain the bigness of their boards and the desirability for having a large variety of talent and information at hand in the council-room. Actual control is vested in an executive committee consisting of heads of departments. The boards of these big mining and metallurgical corporations consist largely of members of the staff, none of whom receives any fee for serving as a director. Indeed the number of directors not connected with the actual management of the enterprise tends to become relatively small. The Granby Consolidated has 13 directors; the Utah Copper, 15; likewise the Inspiration; the Anaconda has 9; but the purely mining companies have smaller boards; thus the Goldfield Consolidated has 7 directors, the Butte & Superior and the Homestake have 5 each. The Calumet & Hecla, which is almost a family affair has five on the board, one of them being the resident manager; the Hollinger has the same number, two of them representing the Tinnius family, which has been associated with the enterprise from the very beginning. In several cases the general manager is a director.

This is a wise practice and is only hindered by the fact that the mine usually is several days' journey from headquarters. The responsibility for the technical operation and for the final result, that of making money for the shareholders, rests chiefly on the manager; therefore it is fair, and it is wise, to put him in full possession of the ideas and confidence of those 'higher up.' While recognizing the wish to give representation to groups of shareholders, it is still a pity that responsibility should be divided among so many. The character and the ability of a group of men is much below the average of them. In the last resort, it is usually one dominating personality that settles the policy of a company and directs its destiny. On most boards there are several passengers. Those that take their responsibilities seriously and act as trustees for the shareholders are few; the majority think they are doing well enough when they protect their own interest and that of the friends whom they represent; but the interests of these may not be identical with that of the minority shareholders. For this defect in company management there is no apparent remedy, except the election of men of high character, and of that there can be no assurance so long as selection is based mainly on property qualification. It remains a serious blemish in collective speculation, such as the operations of a mining company, that the men in charge are not selected for their special fitness. The ideal management would be a managing director, an assistant, and the resident manager. The assistant to the managing director might be the consulting engineer. All of them should be paid handsomely and be under obligation not to play the share-market, so that the proprietary, that is, the whole body of shareholders, might be assured of undivided attention to their business. The more the general direction of a complex technical enterprise is in the hands of bankers, brokers, and book-keepers, the less it is likely to achieve its purpose, which, in mining, is to make money out of the exploitation of mineral deposits. There should be a profession of directors, men qualified by training and experience to conduct the general affairs of industrial enterprises. The present writer remembers his first contact with a board of directors; he had supposed that they would be men chosen, of course, on account of their unusual sagacity; he expected to face a group of retired mining engineers or men otherwise versed in the matters to be discussed. He will never forget his disillusionment, when, traveling from California to London, he found his directors were a lot of duffers, one of them titled, all of them supremely ignorant of the matters in hand, and the only one that had even seen a metal mine, through a telescope, was the most unpractical of the lot. That was many years ago. In those days a companion picture might be found in New York. On both sides of the Atlantic these things are done better now; but still it seems a waste of time and of good brain-tissue to put persons wholly unversed in technology on the board of a mining company and to entrust the direction of its affairs to a mixed aggregation so numerous as to scatter responsibility rather than crystallize decision.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matter pertaining to mining and metallurgy. The Editor welcomes expressions of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

The Flotation Process

The Editor:

Sir—I have read with appreciation the lucid account of the development of the patents and of the mentality of the patentees which appropriately appeared in your issue of April 1. Perhaps the following description of a process used by me for some time past may be of interest. My first use of it anticipated all the ruling patents except that of Mrs. Carrie Everson, but unless the Colorado Scientific Society unearths further biographical details it would be difficult to cite her in support of prior use. On the other hand, it resembles the more recent developments of the process to a remarkable degree. The selective agent used was an oil-residue obtained as a by-product in the manufacture of nitroglycerine. The quantity used was minute; I can give no actual figures, but a small supply lasted a long time. Atmospheric air was introduced by vigorous agitation, resulting in the formation of a froth that was removed by a form of scraper-conveyor specially made for the purpose by a well-known Sheffield firm. My earlier experiments were not uniformly successful, values (permit the word in this connection) tending to accompany the waste matter, and necessitating the occasional use of alum as a corrective. Apart from this no chemical agent was employed. Now, Sir, in view of recent and pending litigation, would your advice be to grow whiskers, or to run the risk of an injunction and an action for the recovery of royalties?

R. T. HANCOCK.

Jemaa, West Africa, May 28.

[Grow the whiskers; they will be handsome. An injunction and the attempt to collect royalties will prove unpleasant and unprofitable. Dedicate the process to the mining industry and feel proud of your abrogation.—EDITOR.]

The Engineer and Business

The Editor:

Sir—The relation of the engineer to business continues to interest both engineers and business-men. At the inaugural meeting of the Engineering Section of the Natal Society for the Advancement of Science and Art in Durban, South Africa, on May 19, the chairman, J. Roberts, said in part, "The business-man generally found at the head of manufacturing concerns is likely to be only superficially informed on the technical details of the business. In some cases the technical man knows that if the

control were placed in his hands the final result would be improved. In the majority of cases, however, the situation is accepted as inevitable, with the result that many times a manufacturing proposition quite sound on the technical side fails from the fact that the control is in the hands of one who cannot conduct the business portion sagaciously. We know of men with only a technical training who have been put in charge of purely selling concerns and who have turned a struggling business into one yielding good profit with quite remarkable expansion. Only an engineer can realize what class of machinery or tools is most suitable to the conditions of the market and how the standard article can be advantageously modified to suit conditions."

Mr. Roberts's argument in full contends that an engineer's training fits him to direct business matters and cultivates in him a capacity for organization. To this opinion many business-men will undoubtedly demur, just as many of the old style of bankers in Wall Street are said to be looking askance at the advertising methods and foreign connections of the National City Bank of New York, the greatest bank in the country, the president of which, Frank A. Vanderlip, secured much of his training while the financial editor on a Chicago newspaper.

In the *Engineering Magazine* for July, is an article with a good deal of sense, even if written in a colloquial style. The author, Leonard M. Cox, suggests that engineers should broaden their outlook to the bigger things of business. He advises them to "take active interest in all public matters; to make a practice of forming judgment on large affairs and then check up in the light of subsequent events; to discuss politics and business with men who know." Mr. Cox adds that "the engineer who talks to his board of directors in technical terms is making a mistake. They want a man who can talk to them in their own language of bonded indebtedness, amortization, fixed and operating charges, and who can decide upon all technical problems involved without obligating his clients to admire his erudition. * * * In the breast of many engineers is a genuine lust for analysis, for the solving of unusual problems. It is as fascinating as chess, and like chess it can absorb spare time and thought that the large-calibre man can afford to give it. A certain young engineer had been selected for promotion to a position of superintendent, when a tempting bit of difficult analysis proved his undoing. The young engineer forgot his executive duties at once and worked day and night on a detail of problems and stresses. The result was a unique and original solution

for maximum economy, a saving of perhaps \$35—and his ultimate transfer to the drafting-room!"

These opinions may be a trifle exaggerated but to a measurable extent similar thoughts are exercising the minds of most men engaged in the mines and industries of this country. The *Journal of Electricity Power and Gas* has stated editorially that the engineer is a man who *ipso facto* has eschewed advertisement and salesmanship. This is not so. Elbert Hubbard, I think it was, said that "advertising is letting people know what you can do, and if you can do anything out of the ordinary, it is of no value to you unless you let people know that you can do it." As expressed by a writer in the July Bulletin of the Canadian Mining Institute, "Merit's no good if no one ever tells." While advertising and salesmanship cannot be applied to engineering to the same extent as other industries, and while the advice of *Engineering & Contracting* that "if you want to attract attention, get in front of people and bother them" is not to be commended, yet a good deal more could be done by engineers to strengthen their profession than has been usual in the past

P. B. McDONALD.

Berkeley, July 15.

Swelling Ground and the Panama Canal

The Editor:

Sir—The *Los Angeles Times* of July 9 had an article by Senator Thomas Kearns on the cause of slides in the Panama Canal, which I read with a great deal of interest. I also have had considerable experience with swelling ground, during my thirty odd years of mining; and I am still having it; but with all due respect to the Senator's superior geological knowledge and greater experience, I cannot agree with him.

If the slides are caused by "gas pressure," as he believes, then why doesn't the pressure cease when the ground has cracked loose, making fissures through which the gas could escape?

It is my experience that the swelling element is contained in the material itself, whether solid rock or crushed material or gouge (the latter being a mud, hard or soft).

The mines along the Mother Lode here in California, pretty much all have trouble with swelling ground, and it generally occurs in the gangue and in either wall for varying distances. In some places the area of swelling is narrow enough to be entirely removed by the width of the drift or slope, in which case the swelling continues only from above and below. I have always thought the main cause of swelling was lime, which slakes when exposed to air, or air and water. I cannot accept the Senator's elaborate test of his swelling material as conclusive, since I believe his process of kiln-drying and roasting permitted it to exhaust its swelling qualities, or to destroy it. Had he taken the raw material and placed it in a glass receptacle and added

water, or even let it remain exposed to the air, he would have noted a continuation of the swelling.

A good example of what swelling material will do, after having been removed from any possible gas-pressure, may be seen in Anador county, where the old dump at the Hardenburg mine crawled or moved on an incline of less than 30 degrees, and did so for months after any fresh material had been added to it. But granting the Senator's theory to be correct, then how is the ground at the Canal to be relieved of its gas-pressure?

The experience of sinking shafts and working in swelling ground is not of an optimistic nature. Boring would be useless, since the holes would close almost immediately on completion, unless properly cased, which would nullify their value. Personally, I believe, as do the Canal engineers, that the slides are caused by the weight of the banks on the soft underlying material, with a possible swelling tendency, and when this ground breaks loose and moves, it pushes the soft material ahead of it and causes it to bulge in places. A good example of this may be seen on the line of the Southern Pacific railway between Benicia and Sacramento, where the road passes through some marshy country. When the road-bed was being built the rock-ballast squashed the mud out of place, and raised it in ridges on either side of the track, in some places higher than the road-bed itself.

It is my belief that the only thing that can be done at the Canal is being done, namely, remove the material until the banks have attained an 'angle of repose.' A thorough ditching of the banks to carry off the torrential rain-water should be beneficial. This would permit the banks of the Canal, composed of this rotten porous material, to drain itself and stiffen.

The above is not in the spirit of criticizing the learned Senator. We all wish to see the Canal a success, and it will be.

F. J. MARTIN.

Angels Camp, July 15.

[We have received copies of several newspapers containing the Senator's article. If we remember correctly, he propounded his explanation on the opinion of a mining engineer in his employ, not on his own. In any case, it did not seem convincing, in the light of information obtained from other observers. We discussed the subject of the slides, and the cause of them, in our issue of June 10.—EDITOR.]

CHINA is reported to have exported 13,000 tons of copper coins to Japan in 1915, and dealers in Shantung province are said to have accumulated 20,000 tons more, a total of 33,000 tons, which is nearly as much as the annual output of copper by the Calumet & Hecla company, and nearly half the normal yearly production of copper in Japan.

SALT production of the United States in 1915 was 38,231,496 bbl., averaging 31c. per bbl., equal to \$2.19 per ton, a general increase.

THE MAIN STREET.

HAULING CONCENTRATES.

The Oatman District, Arizona

By Leroy A. Palmer

GENERAL. This district, commonly known as the Gold Road-Tom Reed, and officially as the San Francisco mining district, is situated in the western part of Mohave county, Arizona, about ten miles due east of the Colorado river at the point where California, Nevada, and Arizona come together. It is 27 miles by stage from Kingman, Arizona, and 20 miles from Needles, California, both on the main line of the Santa Fe railroad. The district is on the west flank of the Black range, which separates the Sacramento and Mohave valleys. Drainage from the west slope is directly to the Colorado river.

The Black range is typical of the desert. Elevations in this vicinity are not extreme, the town of Oatman having an altitude of 2500 ft., and most of the slopes are moderate, in comparison with the rugged topography of the Rocky mountains and the Sierra Nevada. Occasionally a fault-scarp or some other geologic feature, as the outcrop of an erosion-resisting dike or vein, gives local abruptness to the hills, but, in general, the slopes are such as can easily be scaled.

Climate and vegetation are characteristic of the southwestern desert. The winters are moderately cool with occasional short periods when the thermometer falls well below the freezing-point. The summers are blazing hot, the mercury soaring to 115° and above, but the humidity is low; there is a daily breeze and the nights are pleasantly cool.

The precipitation is scanty, about five inches per annum in the valleys and somewhat more in the mountains. The vegetation is typical of the arid regions of the South-west; greasewood, various cacti, including the giant *ocotilla*, sage-brush, yucca, this last being the

only growth in the locality that is suitable for fuel.

HISTORY. The first discovery in the district was made in the early 'sixties by a party of Californian prospectors headed by John Moss, who found very rich ore on what is now known as the Moss mine, about four miles north-west of the Gold Road. A rush of considerable proportions followed but conditions were rigorous, even for the hardy pioneers, and the Indians were so hostile that prospecting was unsafe except in large parties, something to which the prospector is naturally averse. But about ten years later the number of the inhabitants was augmented by many who worked their way down from Pioche and other Nevada camps so that the Indians withdrew farther into the mountains, the prospectors enlarged their field of exploration, and several new districts were discovered.

Two attempts at milling the ore were made in the early days, one by the Moss mine and one by a custom-mill, but both were unsuccessful. Consequently until the extension of the railroad in 1882 all ore was hauled or packed on burros to the Colorado river, transported by steamer to the Gulf of California and thence by ship to San Francisco, where it was transhipped to the smelters in Wales. Obviously the ore had to be rich to stand such a haul and when the higher grade deposits were worked out operations in the district slackened and the miners scattered, many of them going to the silver discoveries that had been made to the east in the Cerbat range.

The district experienced a revival in 1902. Tom Jones, a Mexican prospector who had been a "blabster" by Henry Lovin of Kingman, and one of the leading ones of Oatman, discovered the Gold Road mine with quartz

ing a stray burro. The mine was sold shortly after by Jeneres and Lovin, eventually becoming the property of a French syndicate, which sold it to the United States Smelting, Refining & Mining Co. in 1910.

The Blue Ridge, now the Tom Reed, was discovered two years earlier than the Gold Road, but active operations were not commenced on it until after 1906, when it was sold to the Tom Reed Gold Mines Co. composed chiefly of Pasadena capitalists.

Both of these mines became producers and soon thereafter dividend-payers. Their success stimulated prospecting, several claims were located in the district, and a few of them became productive in a small way. But the real awakening, in the spring of 1915, is due to the United Eastern.

The Tom Reed, which was working through the Tom Reed shaft, toward the south-east end of its ground, went about half a mile to the north-west and sunk a shaft on its Olla Oatman claim. A cross-cut was started from the shaft, but found no vein where it was expected. This fact became known to George W. Long and J. L. McIvor, two practical miners with a good working knowledge of geology. They formed a theory as to the whereabouts of the missing vein, and, while working underground in the Tom Reed, made such observations as confirmed them in their belief. They then bought from J. F. McConnell and Joe Perrizzo the ground on which they believed the vein was to be found, financed it for limited development work, and commenced sinking a shaft in September 1914. At 200 ft. they cut the vein and at 300 ft. they drove a cross-cut, which, in February 1915, broke into the vein where it had a width of 30 ft. and assayed up to \$190 per ton. Naturally this awakened interest in the district and attracted the attention of men of reputation and capital, so that a year later claims were located over an area of 120 square miles. There has probably never been a new district in which so much cash was paid into the treasuries for actual development work and so many competent mining men were in charge of operations as at Oatman. At this time there are approximately 125 companies operating all told, and about 4000 people scattered through the five towns in the district.

GEOLOGY. On casual examination, the geology of the district appears to be comparatively simple, but, as one goes into it, complexities appear and it resolves itself into a problem presenting many angles. For the following general outline I can claim nothing strictly original. It is rather the correlation of the notes of several engineers who have given the subject considerable study, checked and supplemented to some extent by my own observations in the field.

Briefly, the formation is as follows: A pre-Cambrian complex, which forms the base of the range, and consists of schist, granite, and gneiss, appears locally as granite-gneiss in limited areas, notably in the vicinity of Boundary Cone peak. Overlying this basement complex is the Tonto group of sharply upturned Paleozoic sediments. These are also of very limited extent, locally

only one outcrop giving a favorable exposure, at a place $3\frac{1}{2}$ miles west of the town of Oatman and a quarter of a mile south of the Times claim, where this group appears as limestone, almost invariably marbled, and as metamorphosed shale.

Overlying the sediments are various flows of presumably Tertiary age. The most important of these rocks is andesite, of which four distinct flows have been recognized. Locally the andesite is labeled as the 'earlier' and the 'later.' The 'earlier' is a typical andesite that rests on the Tonto group, or, where these sedimentaries have been removed by erosion, directly on the pre-Cambrian complex. Following this extrusion came a long erosion interval preceding the outpourings of 'later' andesite. Four different flows, one of which is chloritic, without any erosion-interval, have been distinguished in the later andesite, which is of somewhat greater extent areally than the older.

The later andesite was covered by a layer of andesite tuff, overlaid by latite, and that, in turn, by an amygdaloidal basalt. The latite and basalt do not appear in the immediate vicinity of Oatman, but the ridges thereabouts are capped by the later andesite, which exhibits the pronounced columnar structure usually found most highly developed in the basalts, so that one observing these ridges from a distance would come to the natural conclusion that he was looking at the latest of the flows.

VEIN FORMATION. All of these flows, except the latite and the basalt, were subjected to heavy stresses resulting in a series of profound fault-fissures, which were subsequently intruded with dikes and plugs of rhyolite. These fissures have a general northwest-southeast strike but north-west of the town, in the vicinity of the Pittsburg and Times, is a series with almost due east and west strike. These have generally been supposed to represent a distinct system but more recent observations in connection with development work tend to the conclusion that they are all part of one great fissure system.

The age of all of the volcanics is supposed to be Tertiary. The andesites were Early, the period of faulting and intrusion Middle, and the latite and basalt Late Tertiary, with the possibility of the basalt overlapping into the Quaternary.

Following the intrusion of the rhyolite, veins were formed along the dikes and adjacent thereto, and in a few instances, as at the Gold Road, in the dikes themselves. These veins are of calcite and were probably formed by hydro-thermal action on the feldspar of the andesite, this action being accompanied by a silicification of the andesite in the immediate vicinity of the veins. The andesite when silicified much resembles quartzite and, resisting erosion to a greater extent than the unaffected rock, stands up in many prominent ridges or combs by which the veins can sometimes be traced and which have given rise to a local term, 'quartzite dikes.'

The calcite proper is barren, but following its deposition the veins were strike-faulted, thus allowing the upward circulation of silicious solutions containing gold, which was deposited by metasomatic replacement of the

calcite. The veins show distinctly the banded structure characteristic of deposition from upward circulating solutions, and specimens of quartz pseudomorphic after calcite are not rare. Occasional specimens are found in which the gold appears to be deposited in the calcite itself, but it is probable that the microscope would show that it is associated with some quartz. As a rule the walls carry very little gouge, but they are usually clean-cut and the veins are rarely found frozen.

Thus we have two periods of faulting previous to mineralization and having a direct bearing upon it. There was also a third period, which was subsequent to mineralization. Following the deposition of the gold ores intense lateral stresses brought about a series of transverse faults at right angles to the major faults, in which the throw was largely horizontal and limited to a few hundred feet. This resulted in a displacement of the veins, but had no mineralizing effect, as evidenced by the fact that the transverse faults are barren except for

such small amounts of mineral as have been carried onto the fault-plane by the drag.

So far, all of the orebodies are in what may be designated for the occasion as the 'middle' andesite, that is, the uppermost of the flows as well as the earlier andesite are barren although the veins are found therein. For some time it was supposed that the ore-zone was delimited by the chloritic andesite, but more recent developments have upset this theory, although the occurrence of any ore-shoots in the earlier andesite is yet to be demonstrated. There is no doubt that the veins extend into the pre-Cambrian and some ore of value has been found therein, but at present it is not safe to say what part this formation will play in the future of the district.

The fact that it is customary in the Oatman district to sink to depths of 300 to 500 ft. before attempting to reach the vein has given rise to the general belief that pay-ore is not to be found nearer the surface. This con-

TOWN OF OATMAN AND PART OF THE GOLD ROAD

ception is not strictly true, as proved by such mines as the Times and the Oatman United, at which good ore is found on the surface. This was also the case with the Green Quartz, whose former owner, the prospector who located the ground, kept himself in bacon and beans for several years before selling to the present company by treating in an arrastra such ore as he took out by gophering around by hand, none of his workings being over 50 ft. deep. The ore occurs in shoots that are distributed both vertically and horizontally. Where the latest of the andesite flows, in which the veins are barren, are in place it becomes necessary to reach the orebodies by sinking, but where these flows have been removed by erosion and the productive andesite is exposed, there is the possibility of finding an ore-shoot at the surface.

Another reason for the deep mining at the start is that Oatman must of necessity, because of the low grade of its ores, be a deep-mine camp. For this reason the operators have recognized, fortunately, that their first task must be to prove their mines. For a new camp and one that has attracted so much attention with the corresponding temptation to speculation, Oatman, is remarkable for its conservative development and the lack of elaborate or unnecessary equipment.

The veins of the district can be classified into four different mineral zones, according to the more prominent mines thereon. These zones tend to show a slight convergence toward the south-east, but the junction, if there is one, has not been found, being concealed by the later flows and surficial material.

The veins of the district have been traced over distances of several miles. Their general appearance indicates depth, but as yet a definite prediction as to the persistence of ore cannot be made. As stated, no orebodies of importance have yet been found in the earlier andesite, but development in this zone is very limited. The ground-water level presumably coincides with that of the Colorado river, which has an approximate elevation of 5000 ft., 2000 ft. lower than the town of Oatman. Thus if the ore persists to that depth it will be found oxidized to the level of the river. If this proves to be the case, it will not be necessary to make any material change in milling practice for some years to come.

This account is necessarily brief, for the reason that scientific evidence concerning the geology of the district is still so incomplete, a condition that development is tending to overcome. There are many problems yet to be solved; for instance, as to whether the east-west fissures in the vicinity of the Times are distinct or part of the main fissure system. Do the fissures unite somewhere south-east of the district, and, if so, what is the result? Why are ore-shoots limited to the 'middle' andesite, while the 'earlier' and the upper flows are barren? There have been some interesting theories formed on some of these points and I should like to go into them, but that is properly the privilege of those who are working them out and who will undoubtedly be able to make more definite statements later than I could offer now. Oatman promises to be a fruitful field for the geologist as well as the miner.

The New Anaconda

In a pamphlet entitled 'The New Anaconda,' Eugene Meyer, Jr., & Co. of New York describe present conditions at that great property. The pamphlet says in part: Anaconda is mining, reducing, and marketing at the rate of 330,000,000 lb. of copper annually—approximately one-fourth of the copper produced in the United States, and one-seventh of the copper produced in the world; in addition, it is refining and selling the product of other companies, in some of which it has part ownership, to the extent of 240,000,000 lb.; making a grand total of 570,000,000 lb. of copper—more than one-third of the product of the United States and nearly one-fourth of the total copper production of the world. Anaconda, besides its copper, is producing annually 13,000,000 oz. of silver and 150,000 oz. of gold; is smelting and refining at its custom-plants an additional 4,000,000 oz. of silver and 100,000,000 lb. of lead; it will, within a few months, be producing at the rate of 70,000,000 lb. of zinc per annum. By the end of 1916, Anaconda will be using 126,000 hp., or 700,000,000 kilowatt-hours annually. Electrification has meant a saving of \$3,500,000 to \$4,000,000 annually. Prior to 1915 Anaconda found it impracticable to separate more than 82% of the copper in the ore. With flotation machines installed, the recovery of copper in concentrate has been increased to 96%. The leaching-plant, in which tailings are treated, has a capacity of more than 2000 tons per day and recovers about 85% of the metal in the tailing. Its annual recovery amounts to 7,000,000 lb. of copper at a cost of 8½ cents per pound. As the old tailing piles contain more than 20,000,000 tons, there is enough of this material available to enable the leaching-plant to continue at the present rate for nearly 30 years. These tailing piles are capable of being converted into 200,000,000 lb. of copper. It is a conservative assumption that Anaconda in 1917, with normal prices of zinc, will be able to earn a profit of two cents per pound on its 70,000,000-lb. output—an annual net earning of \$1,400,000 from this new source.

Earnings in Montana:

300,000,000 lb. copper annually at cost of 9c. per pound, copper at 14c.	\$15,000,000
70,000,000 lb. of zinc annually at a cost of 3½c. per pound, zinc at 5½c.	1,400,000

Total	\$22,650,000
Per share	\$9.72

Within the next few years the company should begin to realize on its investment in Chile. It is fair to assume a production of 100,000,000 to 150,000,000 lb. of copper annually at a profit around 5 cents per pound under normal metal prices. Anaconda owns 75% of the operating company in control of the Chilean deposits. This should return an amount equivalent to at least \$2 per share per annum on Anaconda's stock.

Ore Treatment at the West End, Tonopah

By Jay A. Carpenter

A considerable amount of interesting work has been done at the West End mill, as the following notes from the annual report for the past year will show:

There was 56,976 tons treated, with a gross value of \$958,657.

The value is calculated at \$20.67 per ounce for gold, and 50.35 cents for silver. The average metallic content of the ore was 0.245 oz. of gold and 23.42 oz. of silver. Gold extraction of 94.80% and silver of 90.88% are the highest recoveries yet made by the West End mill. The combined extraction was 90.92% of the metallic content, and 92.10% of the money value of the ore. (This latter figure of 92.1% is the accepted method of reporting extraction.) It is to be further noted that this recovery was made by cyaniding only. Concentration was abandoned in 1914, as the additional gross extraction made by its aid was overbalanced by the 8 to 10% marketing cost on the value removed in the concentrate. The cost in 1915 of marketing the products of cyanidation was only 1.7% of the gross value of the ore, giving the high net extraction of 90.4%. This is also the highest annual figure yet attained, and is considerably above the average 1915 figure of 89.75% for the mills of the Tonopah district.

The total recovery of metals was 13,219 oz. of gold and 1,210,037 oz. of silver.

The daily amount treated was 156 tons, which required 22.6 stamps dropping continuously, giving an average of 6.9 tons per stamp-day. Of the daily tonnage, 39 was custom ore, and 47 was the disputed Jim Butler v. West End ore which was treated as custom. The custom ore was irregular in quantity, varying from 86 to \$96 per ton, and ranged in character from oxidized-ore screenings to the hard flint of the Kernick ore. These variations made it impossible to keep the consumption of chemicals and power to as low a point as could be done with a fairly consistent tonnage and grade of ore, and it required great attention to details of plant operation to obtain equal extraction. The sampling of all ores, with the control assays and necessary supervision, introduced a new expense in milling charges. However, if the treating of custom ores added to the expense of milling, it was far over-balanced by the direct profit from the milling of these ores. In addition to the direct profit there was an important indirect profit accruing from the increased daily tonnage milled.

During the last six months of the year the average value of the ore treated was \$20.10. This was a composite of Tonopah ores, being mainly sulphide ores. A gross extraction of 92.1% was obtained, giving a net extraction of 90.5%. Although there was no concentration, the average titration of the strongest solution in the

mill, being that of No. 1 agitator, was 3.5 lb. of potassium cyanide and 0.7 lb. of protective sodium cyanide. Sodium cyanide consumption was 2.9 lb. and 1 lb. of zinc shavings. These results are worthy of mention, as they mark a high point in the treatment of Tonopah ores without concentration.

The year 1915 was notable for its advance in price of nearly all materials used in milling, but such increases are usually met in all industries by greater economy and a closer study of costs. We are pleased to state that in our case, with a reduction in daily tonnage from 179 tons to 156, and with an increase in the gold and silver contents of the ore from 18.7 to 23.66 oz., the total direct milling costs show a decrease of 3c. per ton. With the decreased tonnage the total cost of labor and power per ton was held at the same figure, and with a 25% increase in the metallic content of the ore the cost of supplies actually decreased 3c. per ton.

The following table shows the main items of cost for 1915, and those of 1914 for comparison:

	Amount Used per Ton		Cost per Ton	
	1915	1914	1915	1914
Labor (average of \$4.50 per shift), shift	0.156	0.161	\$0.704	\$0.724
Power, kw.-hour	36.0	35.6	0.526	0.506
Sodium cyanide, pounds.....	2.6	2.83	0.567	0.600
Cut sheet zinc, pounds.....	1.21	1.34	0.179	0.126
Lime, pounds	3.88	3.95	0.028	0.032
Lead acetate, pounds.....	0.66	0.43	0.074	0.07
Fuel-oil, gallons	3.19	3.19	0.322	0.321
Water, gallons	226.0	216.0	0.71	0.85
Pebbles, pounds	7.39	6.05	0.07	0.05
Tube-mill liners and supplies.....			0.06	0.058
Shoes and dies			0.00	0.00
Other supplies			0.07	0.07
Total direct milling costs.....			\$2.74	\$2.768
Indirect costs without depreciation			0.21	0.202

Total direct and indirect without depreciation, \$2.95, \$2.970

Special features that held the interest of the miller during 1915 were as under:

Six tons of manganoid steel balls were substituted for the six-ton load of Danish pebbles in the 5 ft. 15 in. tube mill. There was a sharp increase in the power required for the mill, but less power per ton ground. The saving in power was over-balanced by the greater cost per ton for the steel balls. Later, the mill was reduced to 3 ft. 5 in. diam. and charged with steel balls, resulting in a considerable increase of tonnage, and decrease in the power required for the mill, and the cost of Danish pebbles for the 5 ft. mill. On account of the saving in power per ton ground, the test is being continued with a 2 per cent to determine the consumption of steel balls. Under the

favorable conditions of the 3-ft. diam. mill. In 1915, using mostly Manhattan, Nevada, chaledony pebbles in the 5 by 18-ft. tube-mills, the consumption per ton of ore was 20% greater, but the total cost per ton of ore ground was 20% less than in 1914 when Danish pebbles were mostly used. The Komata shell-liner placed in one of the 5 by 18-ft. mills in 1913, with the idea of reducing the cost of shell-liners 50%, has given the following results: life of plates, 22 months; life of angles, 6 months; while filler-bars were not worn at all. All this material was purchased from the local foundry, and the cost per ton ground was 2c., which is 33% of the cost when using the smooth liners.

In order to hasten the settling of light slime that lies close to the surface of the Dorr thickeners, an experiment was tried in one thickener of placing $\frac{1}{2}$ -in. square sticks 4 in. apart horizontally, and projecting 3 ft. vertically below the surface of the solution-level. Due to the daily change in character of the ore milled, accurate settling data have not yet been obtained, but the originator of the idea demonstrated a great improvement in settling in his experimental tank thus equipped.

During the year one of the Trent agitators was equipped as a replacer, to determine the feasibility of replacing the rich solutions of the agitator pulp with barren solution and then with water without recourse to the canvas leaf-filter. It was shown that it was possible to maintain a barren zone in the bottom of the replacer and thus replace solutions by this method; but, like the continuous-decantation system, although to a lesser degree, the extra tankage required did not justify a change from the present leaf-filter.

The most interesting and profitable experimental work of the year was a study of the mill solutions to determine what saving could be made in the use of cyanide and zinc without lowering extraction.* The result was an increased extraction, as shown in the figures given above for the last six months of the year. The saving in chemicals is shown by the fact that during 1915 we used 0.126 lb. of sodium cyanide per fine ounce of gold and silver bullion, compared with 0.170 lb. in 1914, a saving of 26%; and in 1915 we used 0.056 lb. of zinc shavings per ounce of bullion, compared with 0.081 lb. in 1914, a saving of 31%. While the 1914 results compared favorably with standard practice of this district, the 1915 consumption of cyanide and zinc would have been about \$16,000 greater had the 1914 consumption figures prevailed. This would have increased milling costs 28.1c. per ton.

During the year considerable testing was carried on to find out if the flotation process could be used instead of cyaniding on West End ore, or as an adjunct to cyaniding. Although flotation can make an equal extraction with cyaniding on sulphide ores, it was decided that there was no field for flotation at present in the mill, as some of the ore is oxidized, and there is at present no satisfactory method of treating silver concentrate locally.

It is to the credit of the mill-crew that, due to their

observance of Safety-First the year passed with only minor injuries, and no call was made on the State insurance fund.

Gold in Bolivia

A gold nugget weighing 14 lb. was recently found in the placer mines of Benedicto Goytia at Chuquiguillo. This nugget has a maximum diameter of 13 centimetres (1 centimetre = $\frac{1}{2}$ in.) and a maximum and minimum thickness of 8 and 3 centimetres, respectively; it is valued at \$4,000. In the gravel of this same river another celebrated gold nugget, worth \$4500, was found by an Indian miner in the seventeenth century, and was placed on exhibition in the Museum of Natural History at Madrid, Spain. Much of the gold in the possession of the Incas at the time of the invasion of the Spaniards 384 years ago is said to have been obtained from the Chuquiapu and Chuquiguillo rivers. The name of the latter river means in the Aimara Indian language 'inheritance of gold.' In Bolivia gold is widely distributed in veins and placers. Along the rivers which run in a north-easterly direction following the eastern slopes of the Andes, there are extensive deposits of auriferous sands of great richness. The Chuquiapu, or river of gold, upon which La Paz, the capital of Bolivia, is situated, contains within the city limits auriferous gravel washed down from the slopes of the Andean range, and during the colonial period the gold-placer deposits of this river in the vicinity of La Paz were profitably exploited by the Spaniards.—*Bulletin of Pan American Union*.

Chromite

The only commercially important ore of chromium is chromite, which is an oxide of chromium and iron, FeCr_2O_4 . In California the iron is likely to be replaced by magnesium, and the ore is found in serpentine. Chromite is usually sold on the basis of 50% of chromic oxide ('chromic acid'), Cr_2O_3 , on which basis it brings \$12 to \$30 per ton at New York. The wide variation in price is due to the irregular and uncertain condition of the market, which is affected spasmodically by imports.

The production of chromite in the United States during 1915 was 3281 long tons. The quantity imported was 76,455 tons; this came from New Caledonia, Rhodesia, Portuguese Africa, Quebec, and Greece. The domestic production is largely from California, which uses most of its output locally, although a little is shipped to the Eastern States at a freight rate of \$11 per ton. The Quebec deposits have attracted attention since a revival of mining during the past two years. During 1915, Quebec shipped 10,087 tons of chromite to American buyers in Pennsylvania steel districts. New Caledonia, the French island in the South Pacific between Australia and Fiji, has been the world's greatest producer of chromite, having mined as much as 82,806 metric tons in one year. Of late years Rhodesia has been an important producer.

An Improved Pneumatic Flotation Machine

By James M. Hyde

Having had occasion to introduce concentration by flotation into a mill where the flotation machine would have to be in charge of the table-operator, whose time was already fully occupied with his regular work, it was necessary to design an apparatus that would give a maximum recovery with a minimum of attention.

In order to meet this contingency, a machine was designed containing sundry novel features. Details are shown in the accompanying drawings. The body of the machine is a rectangular tank with a sloping bottom and overflow sides. Pulp from the launder (1) enters the feed-chamber (2) and flows into the flotation-chamber, where it passes over the cast-iron air-cells (4), through the upper canvas surface of which compressed air is being forced. The air is supplied through the hose (5) from the header-pipe (6). Each air-cell is regulated independently by a valve (7). The air rising through the previously oiled pulp builds up a bed of mineral-bearing froth above the water-level; this froth flows continuously over the lip (8) and is carried away by the launder (9) and the cross-launder (9a). The bed of fragile froth, which readily breaks down unless air is constantly bubbling up beneath it, is prevented from flowing over the tailing-discharge, where no air is rising, by a partition (10) that divides a dead-water space (11) from the frothing-chamber. The bulk of the tailing is discharged through the valve (12). The deflector (13) guides any bubbles carried toward the tailing-valve by the flow of the pulp back into the frothing-chamber. The deflector (14) causes a counter-current of froth to flow toward the feed-end of the machine. Slime-tailing flows through the opening (15) and the swing-pipe (16) and through the drain-pipe (17) and joins the sand-tailing in the main tailing-launder (18). The swing-pipe (16) may be fastened at any desired height by engaging the proper link of the chain (20) over the nail (21). When the valve (12) is set by the handle (22) so that the valve does not permit quite all of the tailing to flow through it, the position of the swing-pipe fixes the height of the water-level, which will not vary until the pipe is re-set. The novel features of this machine are:

(1) Individual Air-Cells. This feature is of prime importance. There is no possibility of leaky partitions

permitting air from one cell to leak into and be discharged from another. A perfect distribution and control of air is therefore possible. The air-cells may be kept on hand ready to be put into the machine and if a leak comes in the canvas in any part of the machine, the leaky cell may be replaced in less than five minutes and the canvas changed at leisure. Thus better work and more continuous service is ensured than would be the case if the whole canvas had to be changed at once.

(2) No Froth Over Tailing-Discharge. This ensures a maximum recovery. The 'mineral' in the froth that breaks down over the tailing-pocket is lost, as no air is rising there to re-float it.

Longitudinal Section

Cross Section

SECTION OF THE FLOTATION MACHINE

3 Counter-Current of Froth Toward Feed End. This also assists in attaining a high recovery by making all of the froth that rises at the tailing end of the machine flow quickly away from the danger zone.

4 Constant Water Level at any Desired Height. By setting the sand-tailing valve so that not quite all of the tailing is discharged through it, and then setting the swing pipe at any desired point, all fluctuations in flow are positively taken out of and the water level remains at the determined point. The final water level is always visible to the operator from the dead-water compartment.

5 Amount of Attention Required. The test of this machine is tested as in any other machine also used for three Chulavilla mills and 2240 Wells tables. The constant water level device and the improved position of the tailing, which is easily adjusted, account for the fact that the machine requires so little attention.

The machine has a capacity of 100 tons per day.

treating pulps that are much more dilute than it has been considered possible to treat satisfactorily, but dilution of the slime-pulp should be avoided as far as possible by de-sliming with a minimum amount of water after each crushing operation before thorough classification, jigging, or tabling is attempted. By following this plan the bulk of the classification water, and the jig and table water, can be kept out of the slime or flotation-feed.

The oil-feeder, which has been used so satisfactorily with this machine is of the type used by the Anaconda company and was all ready to install when the description of the Anaconda feeder appeared in the *MINING AND SCIENTIFIC PRESS*. It consists of a revolving disc on which are mounted cups that raise the oil from a pan and discharge it into a tray, from which it flows to the ore-pulp, and mechanism for driving the disc with a variable speed. This feeder is much more positive than any form of valve, is less trouble than any kind of a pump, it can be regulated and set to give any desired amount of oil, and will continue to feed exactly that amount. The feeder shown in the photograph is made up from parts that are standard and with accessories that can be obtained or manufactured anywhere.

Referring to the photograph, (1) is a worm-gear speed-reducer, such as is used in window-display work. This is regularly provided with a cone-pulley, but as it was necessary to actuate the oil-feeder from a line-shaft running at 240 r.p.m., a wooden pulley was fitted over the cone-pulley, so that a flat belt could be used. The speed-reducer has a ratio of 48:1. The wooden disc (3) was fitted to a plate regularly attached to the speed-reducer. A buffing-head (4), to one end of the spindle of which a wooden disc (3a) had been fitted, was so set that the discs (3) (3a) were off-centre. Motion is transferred from (3) to (3a) by a leather-faced wheel that runs freely between fixed collars on the round rod (6), one end of which is threaded so that the position of the wheel (5) may be varied. A yoke support (7) threaded at one end, supports the rod (6), which has a hand-wheel at one end and a lock-wheel at the other. A circular disc (9) is attached to the spindle of the buffing-head. To the face of this plate four 32-calibre cartridge-shells were attached by flat band-spring standards. It is necessary to set the cups out from the plate so they will drip freely into the drip-tray, not shown in the photograph. Any number of cups may be used. The spring (10) ensures contact between the driving disks (3) (3a) and the wheel (5).

This arrangement gives absolute control of the oil-feed. Many variations of it will suggest themselves, but this one has proved satisfactory and is made of standard parts easily obtainable. If many were to be made, the plates (3) (3a) could be made of cast iron and the stand of the speed reducer could be made as high as the stand of the buffing-head.

It has been found that satisfactory oiling is obtained by adding the oil to the pulp before it goes to an elevator to be raised to the level of the flotation-machines. I have found that a launder in which square blocks of one-third

to one-half the width of the launder are placed alternately along the sides makes an efficient mixer, or any kind of a vertical or inclined cascading device is serviceable. The launder with hindered flow is excellent, it uses a minimum of head-room, and requires no power.

The details of the method of dressing the individual air-cells are shown in the accompanying photograph, which makes plain the method of attaching the canvas with a wooden parting-stop, and of obtaining a flat surface by covering the canvas with wire hardware-cloth. The strip across the centre is punched-screen and may be omitted.

It has become customary in introducing flotation machines to the mining public to present genealogy in order to establish their respectability. The following family tree is presented for the improved machine herein described.

The first successful commercial application of flotation concentration on a large scale was the use of the Potter and Delprat processes in the treatment of Broken Hill zinc-middling. In this work hot acid solutions reacting upon the calcite of the ores generated carbon dioxide gas, which, with the assistance of no other oil than that in the exhaust-steam by which the solution was heated, caused the zinc sulphide to rise and overflow as a froth. Potter used several devices in his work, the final one being a pointed lead-lined tank. Delprat's patent shows a tank with a bottom sloping from the feed-end to the tailing-pocket and provided with an overflow for the removal of the mineral-bearing froth at the water-level.

At about the same time, Alcide Froment, in experimenting with the Elmore bulk-oil process, observed the effectiveness of gas bubbles in floating slightly oiled particles. Three students of the University of California also independently observed the same phenomena and described the agitation-froth process in the California Journal of Technology for November 1903.

In 1903 Sulman and Picard broadly described the method of floating certain minerals as a froth by introducing a gas into an oiled pulp in a patent in which one form of apparatus suitable for carrying on their process was described and figured as a tank in which revolved a coiled pipe through the perforations of which air was introduced into the pulp with aspirated oil. The coil was to be revolved so as to cut the air into small bubbles and mix it with the pulp. The tank had a sloping bottom and received the pulp at one end, discharging the tailing at the opposite end, with an overflow for the mineral froth.

In 1910 Theodore J. Hoover and Minerals Separation Ltd. took out a patent in Great Britain, but not in the United States, in which was described a process for introducing gas into an oiled pulp through a permeable medium with the object of causing floatable minerals to rise and be separated from the rest of the ore.

In this patent various permeable media, such as coke, porous ceramic materials, and fabrics were set forth as fit materials through which to introduce the gas into the pulp. A number of types of apparatus were suggested.

In 1912, or thereabouts, Callow introduced into use in the United States an apparatus for causing the flotation of oiled minerals by the use of air introduced through canvas. His machine consisted of a rectangular tank having a sloping canvas bottom from beneath which air was introduced into an oiled pulp. The tank received the oiled pulp at one end, discharged the tailing from the opposite end, and overflowed the oiled mineral as a froth over the sides of the tank.

The machine described herein may be considered the section, the bottom slopes to provide for the flow of a pulp containing sand, the pulp is fed in at one end, the tailing is discharged from the opposite end, and an overflow lip is provided for collecting mineral particles buoyed to the top by bubbles. The individual characteristics that it possesses have been previously described and have been evolved to make the machine effective and easy to operate.

The machine described herein may be considered the

THE HYDE FLOTATION MACHINE.

lineal descendant of the Delprat and Sulman & Picard devices, the suggestions contained in the Hoover-Minerals Separation patent and the Callow machine. As in the others, the containing tank is rectangular in cross-

SOUTH AMERICAN TARIFFS have always been difficult for North American shippers to understand. It is truly said that the greatest obstacle to trade between nations is a complicated and varying tariff system. Yet import duties are the principal source of revenue for many governments. In South American countries, when money is wanted for a new project, what is called a sur-tax is added to the regular tariffs. The sur-taxes are kept separate from the regular duties, which have likely been assigned to foreign holders of government securities. Other vexatious imposts on imports include fines for failing to observe formalities, or for inexact statements in the invoices; many of these violations by shippers are unintentional. New tariff laws have been suggested for the South American countries, and have been adopted in several of them, notably

Chile. The Department of Commerce of the United States has published a report that explains in detail the tariffs of the South American countries, having been made by visiting the countries in question.

SHOWING METHOD OF DRESSING INDIVIDUAL PIECES OF ORE.

Gold-Saving on Dredges

By Howard D. Smith

During the last ten years little change has been made, until recently, in gold-saving on dredges. Long and costly experience demonstrates that saving in the sluices must be accomplished by simple riffles, fed with quicksilver, that clear themselves.

Hungarian riffles, consisting of wooden bars protected on the top by a strip of steel, are now standard practice. Formerly riffles made of angle-iron were in general use, but these were found to give more difficulty in cleaning-up, while first cost and maintenance were higher. Prior to this, cocoa matting and expanded metal were discarded

content consequently is too uncertain to be useful. Attempts to determine the gold content of the tailing directly by following the principle of taking part of the tailing part of the time will never give conclusive results. Operators thus far have been unwilling to spend the money necessary to make a test on the principle of taking all of the tailing part of the time. The amount and velocity of material to be dealt with, as well as the inaccessible position of the end of the sluice, in some cases below water-level, explains this. Re-handling *in toto* the ground previously dredged has come about where it was

FIG. 1. NEILL JIG AND ECCENTRIC DRIVE.

in California. Owing to the scouring action of the mass of sand and water running over the sluices, amalgamating devices that expose quicksilver-coated surfaces to the action of the current have all resulted in failure, and this despite the fact that some of the devices give excellent results where small quantities of material and low current-velocities are involved. Many years ago this condition suggested the making of a concentrate that could be treated subsequently, but until recently no means at all suitable could be found.

The idea prevailing in dredging circles that gold-saving was efficient did much to prevent attempts to solve the concentrating problem. This was owing, in part, to the fact that approximately 90% of the clean-ups came from the first few feet of sluices and but little from the tail-sluices. Figures for the 'heads' are, at best, an approximation. There is only one thing definite about the occurrence of gold—lack of uniformity. Anyone who has attempted to check a rich drill-hole with others as close as a yard away becomes keenly aware of this fact. Estimation of losses by subtracting recovery from known

necessary to move a dredge through tailing-piles to reach new ground, and also by design. Very little gold was recovered by this treatment in the case of free-washing gravel where the original gold-saving was at all efficient, but considerable recovery, as much as seven or eight cents per cubic yard, was made where the ground contained clay not thoroughly disintegrated by the first washing. Obviously none of these operations determined whether more gold could be saved by other means than the standard riffles used in both treatments.

During several months in 1914 the Lyons Syndicate, in which Frank Griffin, Maurice Griffin, and O. B. Perry were interested, conducted tests at Natoma to determine whether the ideas of Robert Lyons, concerning the amalgamation of gold by the use of zinc amalgam, would prove practical on gold-dredges. The results were unsatisfactory, but, incidentally, important data concerning losses were obtained. From the results of the test on the Natoma No. 7 dredge it was estimated that when recovery from about 135,000 cubic yards by standard equipment was 23 cents per yard, approximately \$220

per day was being lost. The large loss on this dredge is explained by the clayey ground containing much rusty gold, which would not amalgamate.

Tests on No. 1 dredge, working in free-washing ground, containing no rusty gold, with a yardage approximately twice as large, and a recovery about 9c. per yard, indicated a tailing-loss of a little less than \$40 per day.

FIG. 2. SHAKING AMALGAMATOR.

The matter of selecting a concentration scheme to deal with conditions on Natoma No. 7 was then taken up. Any concentration device to be successful on a dredge must occupy small space, run efficiently with little attention, and have large capacity. The Neill jig, shown in Fig. 1, appearing to possess these characteristics, was accordingly tried. In order to brighten the gold a $4\frac{1}{2}$ -ft.

FIG. 3. CROSS-SECTION SHOWING ARRANGEMENT OF JIGS, HARDINGE MILL, AND AMALGAMATOR.

Hardinge mill, using pebbles from the tailing, was erected, followed by a shaking amalgamator and copper plates. The general scheme is shown in Fig. 2. Results are as follows:

Interval	Cu Yd.	Value per yard cents	Total recovery \$	Amalgamator recovery %	Amalgamator recovery per cent yd. of total
Dec. 20, 1915 to Jan. 27, 1916.	1,422.20	14.11	18,701.93	2129.79	1.51
Jan. 27, 1916 to Feb. 14, 1916	128.310	11.68	18,929.11	3031.67	2.55
Feb. 24, 1916 to Mar. 31, 1916	162.950	9.90	16,136.02	3290.70	1.96

The progressive improvement shown was brought about largely by better adjustment. Installation of a leveling device for the amalgamator was also beneficial.

A sizing test showed that 43% of the gold passed 100-mesh and all passed a 20-mesh screen.

Clean-ups of tail-shutes before the addition of the jigs from a point where the jigs would discharge tailing when installed to the discharge in the pond, indicated that of the gold saved by the jigs and following apparatus, from 90 to 97% would otherwise have been lost. These results were gratifying, notwithstanding their not being entirely conclusive. The gold content of the gravel was only ap-

FIG. 4. PLAN AND ELEVATION OF TABLES SHOWING POSITION AND DRIVE OF JIGS AND MILL.

proximately the same throughout the comparative tests.

Under the distribution scheme on Natoma No. 7, although the amount of sand going to each side of the dredge is approximately equal, more gold is carried to the port side of the dredge, the side opposed to the rotation of the screen. Consequently, a comparative test could not be made by using rifles, only, on one side and jigs on the other. The distribution shown in Fig. 4, which is in use on Natoma No. 4, divides the gold, as well as the sand, more equally between the port and starboard sides of the dredge. For this reason it is hoped that the management will shortly make a more conclusive test on this boat. The installation on Natoma No. 10 is similar to that on Natoma No. 7. There is, however, much less rusty gold than in the case of Natoma No. 7.

Results at Natoma No. 10 are as follows:

Interval	Cu Yd.	Value per yard cents	Total recovery \$	Amalgamator recovery %	Amalgamator recovery per cent yd. of total
May 7, 1916 to June 1, 1916	291.40	1.18	343.05	1.18	0.40
June 1, 1916 to July 2, 1916	18.00	1.18	21.24	1.18	0.07

Data from the plant at Natoma No. 4, where no mill is necessary to brighten the gold, will soon be available. The results obtained in this case are more like what may be expected under average conditions, for the gravel at No. 4 is clean wash and the gold is not rusty.

The increased saving over standard riffles is due not only to the greater quantity of fine gold saved but also of finely divided quicksilver. One extra man per shift is necessary for the efficient operation of a jig plant. Special care should be taken to screen the water fed under the jig-screens so that they may not become clogged.

In order to place the jigs the most important lower tables were taken out. While this increases the load on the upper tables, the excess material is distributed over so many of the tables that the efficiency of the riffles is not impaired. It is hoped that it may prove safe to discard all the lower, and part of the upper, tables by placing the jigs in the tables instead of in the tail sluices.

The development of the jig and other gold-saving devices is due to the efforts of F. W. Griffin, L. D. Hopfield, and Edward Strouse, of the Natomas Company, together with the cordial co-operation of the general manager, Emery Oliver. The results given are not held to be representative, but are interesting, and with the extension of the jigs to other dredges, together with experiments now being carried out on the Feather river, will, in the near future, give data relative to the more general application of the jigs.

THE AMERICAN SMELTING & REFINING Co. received \$54,952,106 from sales of gold during 1915. This is equivalent to more than one-half the annual production of gold in the United States. While the A. S. & R. Co. operates smelters and mines in Mexico, the bulk of its holdings are in this country. The silver production of the company in 1915, partly of course from Mexico and Canada, was \$38,007,727, which is more than the entire annual output of silver in the United States. The company's receipts from sale of lead during 1915 was \$27,027,012, which is equivalent to more than one-half of the total annual production of lead in the United States. The largest item of income for the company was copper, the sale of which brought \$92,356,662, equivalent to over 35% of the country's production last year. The total cash receipts of the company for the year from all sources, principally from the sale of metals, was \$232,281,182. This is considerably more than the annual production of gold in the Transvaal. Dividends paid by the A. S. & R. Co. in 1915 were \$8,002,964; its preferred stock brought 7% and the common stock 4%. The smelters controlled by the company include lead smelters at Omaha, Denver, Pueblo, Leadville, Murray in Utah, East Helena, Kansas City, Selby in California, Monterey and Chihuahua in Mexico. Among the copper smelters controlled are those at Perth Amboy in New Jersey, Hayden in Arizona, Garfield, Tacoma, El Paso, Baltimore, and Aguascalientes in Mexico. The board of directors has 30 members, five of whom are members of the Guggenheim family.

The Murex Flotation Process

This process was invented and patented by A. A. Lockwood. Various blends of crude oils are used in the proportion of 15 to 20 lb. (or $\frac{3}{4}$ to 1%) of oil per ton of ore, to which is added an equal quantity of magnetite, ground to 100-mesh. This mixture of oil and magnetite forms a permanent paint, which, no matter how finely it may be divided or broken up, will always be found to be composed of the two substances in the same ratio. The selective affinity of the oil in the magnetic mixture enables it to adhere to any particle of valuable mineral, either sulphide or oxide, contained in an ore, with which it may come in contact, forming a rich magnetite-oil-mineral mixture containing little or no worthless gangue.

In practice the crushed ore and water, together with a regulated quantity of oil mixture, are fed through a horizontal tube revolving slowly, which contains several hundred pounds of $\frac{1}{4}$ -in. rough iron shot. The shot becomes oiled and collects the mineral particles, both fine and coarse, in the form of a paste that adheres. This paste is continuously broken away from the shot by attrition and flows with the pulp through a screen at the opposite end of the agitator-tube onto a shaking tray which feeds it under a powerful electro-magnet. The coated mineral particles are attracted by the magnet from the flowing stream of pulp to the under side of an endless belt traveling under the magnet at right angles to the shaking tray, thereby suspending them until they are carried out of the magnetic field, when they are washed off by a spray of water, into a concentrate-box provided.

The points of advantage claimed for this process are: first, the ore need only be ground fine enough to free the mineral particles from the gangue, in some cases being crushed only to 5 mm.; second, both sand and slime are treated together in one operation, so that no classification is necessary; third, this process is suited to the treatment of practically all the sulphide ores, and also successfully treats lead, copper, and zinc carbonates and oxides, making extractions up to 93% in some cases.

IN RHODESIA, during the first quarter of 1916, the Eldorado Banket Gold Mining Co. had the following metallurgical results:

Stamps dropping 65.01 days	20
Chilean mill crushing 77.78 days	1
Pans grinding 87.98 days	4
Total ore reduced, tons	12,212
Gold by amalgamation, ounces	5,439
Gold by cyanidation, ounces	1,533
Cost:	
Stamps and Chilean mill	\$0.72
Pans	0.36
Sand treatment	0.13
Slime treatment	0.32
Total	\$1.83

The ore averaged \$11.51 per ton, of which \$6.48 was profit.

Snake Creek Tunnel, Utah

This $2\frac{3}{4}$ -mile adit for draining mines was completed recently near Midway, which is a few miles south-east of Salt Lake City and close to the Cottonwood and Park City districts, in Utah. The interesting features included the concreting of 300 ft., where swelling ground gave trouble, and the overcoming of difficulties due to excessive wetness and hardness of the rock.

The adit was driven by the Mid-West Tunnel Co. on contract for the Snake Creek Mining & Tunnel Co. The purpose is to develop and drain the mines of the latter company, of the Daly-Judge Mining Co. (now the Judge Mining & Smelting Co.), and the Knight claims in the

tunnel for 900 ft. when a contact zone of hard marble and quartzite cut by numerous tongues of basic igneous rock was penetrated. At 10,193 ft. from the portal the adit entered the Clayton-peak diorite stock and has been in this formation ever since. It is a dense tough formation, and very wet.

POWER: Electricity was furnished by the Utah Power & Light Co., which operates a power-plant a mile below the portal, and uses the drainage-water to generate power. Power was supplied at 440 volts.

COMPRESSORS: These were situated at the portal. One Sullivan two-stage type, size 18 by 11 by 14; rated capacity 650 cu. ft. at sea-level, belted to a 100-hp. General-Electric induction motor. One Bury two-stage com-

THE CONCRETED SECTION OF THE SNAKE CREEK TUNNEL.

Park City and Cottonwood districts. Details of the work are furnished by the Judge Mining & Smelting Company.

LENGTH: 14,500 feet.

ELEVATION OF PORTAL: 6932 ft. above sea-level.

GRADE: 0.25%.

WATER-CHANNEL: $3\frac{1}{2}$ ft. deep by 4 ft. wide. Capacity, about 30 second-feet. The theoretical capacity is somewhat larger, but the depth is decreased by a deposit of fine mud.

TIMBER: 10 by 10-in. Oregon-fir caps and posts. Posts are given a slight batter and are set on the solid ground in niches. Caps are not framed, but are set on the posts and wedged in place and a 2-in. spreader is nailed on the bottom to keep the posts in place.

CONCRETE: Swelling ground was encountered about 3000 ft. from the portal. The formation was black limestone cut by porphyry. Timber failed to hold, so about 300 ft. was concreted.

ROCK: Near the portal is limestone dipping 20° north-west, and parallel with the line of the adit. This con-

pressor, size 20 by 12 by 12; rated capacity 900 cu. ft. at sea-level, belted to a two-speed G. E. induction motor of 75-150 hp. Both compressors are connected to a 4-in. delivery-pipe that enters the receiver in the compressor-house and goes then into the adit.

VENTILATION: A No. 5 Root rotary-pressure blower is in the compressor-house at the portal, connected to a 16-in., No. 16 gauge, galvanized-iron pipe, and runs as an exhaust. The blower has a displacement of 196 cu. ft. per revolution, with a speed of 255 r.p.m. and is therefore drawing nearly 5000 cu. ft. of air per minute. Blower is belted to a 35-hp. G. E. induction motor. Ventilation is also helped by a small booster-fan, at the 12,000-ft. point, belted to an air engine. Ventilator-pipe comes in rolled sheets, and the pipes are made by the dump-man at odd times, into 15 ft. lengths with a slip-joint wrapped with canvas and tar. The average temperature in the adit is 55 F. The highest temperature occurs at 5000 ft., where hydrogen-sulphide gas is generated. Temperature here is 59 F. Lowest temperatures in some of the wet places do not go below 52 F.

DRILLING: Formerly No. 8 Leyner drills were used but were replaced by No. 60 Dreadnaught drills. Three drills were mounted on a horizontal bar and operated on an air-pressure of 110 lb. A round consists of 18 to 24 holes varying with the hardness of the rock. Depth of holes drilled, 7 ft. Ground hard and tough, and the drilling cycle usually exceeds eight hours. Water is supplied to the drills from an old receiver placed under a permanent flow in the adit and usually kept within 1000 ft. of the face. Water is piped into the heading from the receiver. Floor of heading is carried 6 in. under grade, so as to facilitate the laying of track and make less drilling in the ditch. Jack-hammers have been used in the ditch. Holes are drilled 2 ft. apart in a single line about a foot from the wall. Ditch-drillers become expert and there is no trouble about breaking the whole ditch at one shooting.

TRAMMING: Broken ore is shoveled off steel sheets into cars of 20-cu. ft. capacity. Gauge of track is 18 in. Tramming is done by mules. There

PROGRESS: Average progress per month for the last two years has been 337 ft. The greatest progress in one month was in August 1915, when 436 ft. was made. The Snake Creek Tunnel is not a place to break records. The ground has always been difficult, and water troubles prevent speed. Since passing 3000 ft. the working has been almost continuously wet, and unusual trouble has been experienced since entering the diorite. Here nearly every crack is saturated with water, frequently under

heavy pressure. Often there are intersecting cracks that make the ground loose and blocky and a good deal of timber is required.

Trouble comes in the heading where a rush of water is encountered. After draining for a short time the pressure is reduced, the cracks

is a switch at 11,500 ft. and a mule works each way from this point. Eight cars are hauled into the heading at a time; the full cars are run into the heading out of the way and the empties are thrown off the track at the side. The mule is then hitched to the full train and takes it out to the switch. In loading the empty cars the one farthest from the heading is thrown back on the track and loaded first, then run out past the other empties and the second one is loaded. The ditch is carried about 150 ft. back from the heading so as to leave enough room to remove the empty cars. The crew usually loads two cars while the other shovelers in the heading are loading six.

The cars have roller-bearings, and the mule hauling from the switch outside has no trouble in handling a 20-car train. It takes about 2½ hours to make a trip from the switch to the dump and back, including the dumping of the train. The track is laid on the solid ground on the opposite side of the adit from the ditch. Long sills are laid 5 ft. apart with short sills spaced between them. Permanent sills are usually kept within 25 ft. of the end of the ditch. Carrying the floor in the heading 6 in. low always leaves a little hill in the track for the inside mule to pull over, but he manages 8 cars.

become plugged with sand and the flow subsides, but when first struck the tendency is for the rock to cave, and it is often necessary to use long 8 by 8-in. crown-bars to hold the back until sets can be put in.

Great Britain's Mineral Output

Production of the principal minerals in England, Scotland, and Wales last year was as follows, in tons:

Mineral	1915	1914
Barium compounds	60,801	45,910
Bauxite (alumina)	11,723	8,286
Clay, etc.	322,708	531,000
Coal	253,179,446	265,643,030
Fire-clay	1,829,746	2,374,068
Fluorspar	25,577	24,688
Gold ore	5,086	47
Gypsum	204,574	220,096
Iron ore	7,876,105	8,984,492
Lead ore	20,698	25,988
Limestone	287,680	334,779
Manganese ore	4,640	3,437
Oil-shale (Scotland)	2,998,652	3,268,666
Tin ore (dressed to say 60%)	6,420	6,635
Tungsten ore	329	205
Zinc ore	12,057	15,419

Simple Tests for Potash

By W. B. Hicks

DETECTION. Potassium is generally found in nature in solution, as soluble salts or saline residues, in organic substances, in alunite, and in silicate rocks and minerals. The following tests have been used by members of the U. S. Geological Survey and may be used successfully, it is believed, by anyone with a little experience in chemical manipulation. They depend on the fact that when a volatile potassium compound is heated in a flame it imparts a characteristic violet color to the flame. Though usually masked by the colors produced by other elements, especially sodium and calcium, the coloration due to potassium is readily seen and identified by observing the flame through a Merwin color-screen.

The equipment¹ necessary for making the tests consists of: (1) Lamp for volatilizing the potash compound. For this purpose an ordinary alcohol lamp with an asbestos wick will often suffice, but a gasoline or alcohol blast-lamp, which requires no wick and which burns with a hot, non-luminous flame, gives far better results. (2) Platinum wire 4 in. long. One end of the wire should be sealed into the end of a short glass rod to serve as a handle, and the opposite end should be bent into the form of a small loop. (3) Merwin color-screen.² (4) Small beaker. (5) Hydrochloric acid. (6) Gypsum or calcium sulphate.

First clean the loop of platinum wire by dipping it in hydrochloric acid and igniting it until the flame is no longer colored. By means of the clean platinum loop remove a drop of the solution to be tested, carefully evaporate it to dryness by holding over the flame, finally ignite, and observe the color of the flame through the Merwin color-screen. The best results are obtained by using a black background, holding the Merwin screen close up against the eyes, and looking through the central section of the screen. If potassium salts are present, the flame will appear reddish to reddish violet, and the intensity and duration of the color will give some idea as to the amount of potassium.

PROCEDURE FOR SOLUBLE SALTS. For detecting potassium in saline residue and soluble salts in general, as well as for detecting soluble potassium compounds in muds, clays, and ashes, proceed as follows: Dissolve a portion of the sample in a small quantity of water, allow the undissolved material to settle out, remove a drop of the clear solution by means of the loop of platinum wire,

and test in the flame as just described for waters and brines.

In tests for alum and other sulphates the clear solution should be poured off from the insoluble residue and some hydrochloric acid added before making the test.

The water used in all such tests should be examined to see whether it contains potassium, as a precautionary measure.

PROCEDURE FOR ORGANIC SUBSTANCES. The substance to be tested is first ignited or burned at as low a temperature as possible until only the ash remains. The ash is then tested for potassium according to the procedure just described for soluble salts.

PROCEDURE FOR ALUNITE. Powder the sample to be tested and moisten it with hydrochloric acid. By means of the loop of platinum wire transfer a portion of the moistened powder to the flame, ignite, and observe the color of the flame through the Merwin color-screen. If potassium is present, the flame will appear deep reddish violet.

Emphasis should be placed on the fact that this procedure is a test for potassium and not necessarily for alunite. Other potash-bearing materials, especially leucite and glauconite, will give similar results with such treatment.

The following simple field-test for the mineral alunite has been suggested by W. T. Schaller. Boil the powdered sample with water or with hydrochloric acid for several minutes; after allowing the powder to settle, pour off the liquid and repeat the operation to insure the removal of all soluble sulphates. Dry the powder and heat to dull redness. Again boil in water and, after settling, pour off some of the clear liquid. To this add a small fragment or a solution of barium chloride. If the mineral is alunite a heavy white precipitate will form. To be sure that the water used in this test does not contain sulphate in solution, it should be tested with barium chloride, and if it gives a marked precipitate it cannot be used.

For this test all that is required that was not included in the equipment for the detection of potassium is a little barium chloride, a small crucible in which to ignite the mineral, and a support for the crucible.

PROCEDURE FOR SILICATE ROCKS AND MINERALS. In order to detect potassium in silicate rocks and minerals, such as feldspar, granite, leucite, rhyolite, glauconite, and sericite, powder the material finely, mix with an equal quantity of pure gypsum, and moisten the mixture with dilute hydrochloric acid. By means of the loop of platinum wire, transfer a portion of the moist mixture to the flame, ignite, and observe the color of the flame through the Merwin color-screen. The red-

¹The equipment here described, except the Merwin color-screen, may be purchased reasonably from most dealers in chemical and laboratory supplies.

²The Merwin color-screen is manufactured and sold by G. M. Flint, 84 Wendell street, Cambridge, Massachusetts, for 25 cents. Hand spectrosopes may be used instead of the Merwin color-screen. These may be had from most dealers in laboratory apparatus at \$7 or more.

dish-violet color will be apparent if potassium is present.

Although with less satisfactory results, as a rule, the test may be carried out by mixing the material to be tested with either hydrochloric acid or gypsum alone.

ESTIMATION. A rough quantitative determination of the soluble potash in any salt may be made according to the method described below. To obtain even approximately correct results the conditions in making up the standard and in carrying out the actual determination on the unknown salt must be exactly the same.

The extra equipment required for this work is a small balance and a measuring cylinder. A hand spectroscope in place of the Merwin color-screen will probably give better results.

Dissolve 1 gram of pure potassium chloride in 10 cc. of water and mix thoroughly. Remove a drop of the solution by means of a loop of platinum wire, dry carefully over the flame, ignite, and examine through the Merwin color-screen. Gradually dilute the solution with measured amounts of pure water, mixing thoroughly and testing in the flame for potash the resultant solution after each addition of water, until the potassium flame can just be seen or disappears altogether. Record the exact volume of the solution at this point, and by repeated trials make sure of the correctness of the value. Designate this value for the standard solution by *S*.

Dissolve 1 gram of the salt to be tested in 10 cc. of water and mix thoroughly. Remove a drop of the solution by means of a loop of platinum wire, dry carefully over the flame, ignite, and examine the color of the flame through a Merwin color-screen. Now gradually dilute the solution with measured amounts of water, mixing thoroughly and testing in the flame the resultant solution after each addition of water, until the potassium flame can just be seen or disappears altogether. Record the exact volume of the solution at this point, and by repeated trials make sure of the correctness of the value. Designate this value for the unknown salt by *X*.

To obtain the percentage of potash expressed as potassium chloride in the unknown salt, divide the volume of the unknown solution at which the potassium flame could no longer be seen, designated *X*, by the volume of the standard solution at which the potassium flame could no longer be seen, designated *S*, and multiply the result by 100. In other words,

Percentage of potassium chloride (KCl) =

$$\frac{\text{Volume found for unknown salt}}{\text{Volume found for standard salt}} \times 100 = \frac{100X}{S}$$

Percentage of potash (K_2O) =

$$\frac{63.5X}{S}$$

Percentage of potassium (K) =

$$\frac{52.44X}{S}$$

GRAPHITE mining is on the increase in Clay and Chilton counties of Alabama, and near Burnet in Texas. The mineral occurs as small flakes in crystalline schist into which some granite pegmatite has been injected. Weathering to 50 ft. in Alabama has reduced milling difficulties.

Belt-Conveyors

Belt-conveyors were discussed recently by A. Robertson and A. McA. Johnston before the South African Institution of Engineers. Two kinds of belts were stated to be in general use, balata and rubber. In normal times a rubber belt costs about 15% more than a balata belt. A balata belt is made of several plies of canvas with balata gum impregnated between the layers. A rubber belt is made of several plies of padded canvas with a covering of rubber on the upper and under sides and edges. It should be recalled that the figures given by these Rand engineers apply to the handling of quartz ore, which is sharp and destructive of belts. For an approximate figure it was found, from average of a number of both kinds of belts, that the cost of the belt alone for handling broken rock was about 30 cents per foot per month, while the cost of the belt for handling sand was about 14½¢. per foot per month. Among the detailed statistics given was that of a 24-in. rubber belt, 182 ft. long, 6-4 ply, which carried sand for nearly six years at the rate of 68 tons per hour, a total of 1,586,764 tons; this belt cost \$3.72 per ft., and the cost of the belt alone was 5½¢. per ft. per month. This is an unusually low cost for Rand practice. As an example of a high cost for carrying fine crushed ore to the mill, a 30-in. rubber belt, 923 ft. long, 7 ply, with ½-in. rubber face, was in service 18 months, carrying 117 tons per hour, a total of 854,000 tons. The cost of the belt alone was 28½¢. per ft. per month; the belt had cost \$5.84 per ft. originally. A balata 30-in. belt, 291 ft. long, 6 ply and with 7 rows of copper stitching, conveyed fine crushed ore for 672 days; the tonnage per week of 54 hours was 5000 tons, and the total amount carried was 397,546 tons. The cost of the belt alone was 11¢. per ft. per month; the cost per ton of material carried was 18¢., and the original price of the belt was \$2.44 per ft. This cost per ft. per month is low for balata belts carrying fine quartz. As to life of belts, a balata 24-in. belt, 750 ft. long and 5 ply, original cost \$1.26 per ft., was used for conveying dump ore to the stamp-mill from a Rand gold mine, operating on an incline of 18° at a speed of 350 ft. per minute; it carried nearly 50,000 tons per month for 27 months, a total of 1,200,000 tons. The quality of the rubber is of the greatest importance in determining the life of a rubber belt.

THE NEW CORNELIA Copper Co., which is opening a copper mine at Ajo, Arizona, estimates that its orebody contains 11,950,000 tons of 1.54% oxidized ore and 28,303,600 tons of 1.50% sulphide ore, a total of 40,258,000 tons averaging 1.51% copper. No overburden exists and the ore is mostly in a series of small hills. For the leaching process of treatment with sulphuric acid the ore is crushed only to 4-mesh.

THE UNITED VERDE EXTENSION MINING Co.'s first dividend of 50 cents per share happens to be exactly equal to the par value of the stock.

Mining in Utah

By L. O. Howard

The embargo on silver-lead ore has been made more rigid. In addition to the curtailment of shipments from Tintie, ordered by the smelters, reference to which was made last month, this restriction has now been extended to most of the other small shippers in this State. Those who have leases or are small mine-owners dependent on frequent shipments for meeting the pay-roll are in a quandary. The lead smelters, having accumulated a large tonnage of high-priced ore, have the situation entirely in their own hands, and the wishes of producers are not likely to have much weight. The only possible thing to do is to await the smelters' own good time. A year ago I went into details of smelting and roasting capacity and showed the possible limits on production. That the curtailment was postponed so long was due to the willingness of the smelters to fill their yards with ore, and it is this accumulation that is also the cause of present conditions, and prevents an early release of the embargo.

Combined with the embargo on lead-silver ore, the poor market for zinc, antimony, and tungsten has helped to burst get-rich-quick booms. Many small owners were making an inflated profit, and dreaming of it as unending. Their awakening has been rude. However, many mines are now able to ship on a lower market that would never have started had prices remained normal. Dealing in shares is dull, so that mining is attracting less attention than a year ago. The strongly fortified producers continue to accumulate large profits. The Utah Copper is breaking all records, the latest being 44,000 tons of ore mined in 24 hours, with 25,000 tons of overburden removed the same day.

Mining prosperity is based on the profitable operations of the rank and file, and it is idle to expect better conditions during the hot season. The share-market is marked for dullness until the man on the street is again interested in something besides the cool breezes and the lure of the trout in the near-by canyons, where he so forgets his interest in mining as to bewail the clatter of the ore-teams.

The road in Big Cottonwood canyon is now in good condition, bridges have been re-built, grades cut down, and all is ready for the experiment with tractors, five of which are at the transfer point of the Cardiff mine at the mouth of South Fork. The first loads will probably be hauled before this letter is in print. Development continues in both the Cottonwoods, but without any startling results. Mines that were made last year are shipping large tonnages, but no new ones have been opened. In Big Cottonwood, the Cardiff and Maxfield continue to do all the shipping. The former will increase its daily rate from 120 to 300 tons as soon as the traction-engines have been established. The Maxfield mine has made a record of two cars per week of ore netting \$100 per ton, and is opening ore faster than it is

being shipped. The stock accumulates little more on account of the heavy tonnage issue.

In Little Cottonwood the South Hecla, a first mortgage payer, is producing the largest tonnage, with other shipments coming from the Alta Con. and Michigan Utah. Some zinc-silver ore has been shipped from the Woodlawn, just over the divide in Big Cottonwood from Alta. This ore averages 27% zinc, 7% lead, 16 oz. silver per ton.

American Fork canyon is in full swing. Three shifts are at work driving adits on the Miller Hill, Duteau and Whirlwind mines. Ore is being broken on the Pacific and on the Bay State. The Texan, Earl Eagle, and Belerophon are developing promising fissures. The Alpine Empire, Stewart, Mountain King, Silver Flat, Wasatch King, North Star, American Fork Con., Silver Dipper, Snuggler, Utah-Centennial, South Fork, Pacific Extension, and Major Evans are employing three to six men each.

Tintie and Park City are shipping heavily despite the curtailment. There is no abatement in new construction at Park City, where long adits are being driven, new mills erected, and old plants re-modeled for larger capacity. Work is being rushed on the electrolytic-zinc plant for the Daly Judge, details of which have already appeared in the PRESS.

Signs of the new leaching-plant of the Utah Copper may now be seen. Two steam-shovels are excavating a mill-site just above and west of the Magna mill, on a spur of the Bingham & Garfield railroad, thus affording excellent transportation facilities. Details of the process are not yet public.

Stress has been laid upon the increased metal output of Utah by the Geological Survey's report for the first half of the year. Its rosy predictions appear warranted by the dividends, which totaled \$10,915,000, an amount in excess of that for the whole of 1915. Utah Copper is the heaviest contributor, having paid \$8,231,500 to July 1. Whether a record of \$20,000,000 shall be made for the year depends upon the performance of this one company. Since its copper is sold well ahead at high prices, and production is heavy, it is probable that its total will be surpassed. Fourteen other companies contributed to the record. They are the Centennial Earle, Chief Consolidated, Iron Blossom, Gemini, Mammoth and May Day, of Tintie, with a total of \$1,083,000, the Utah Copper, Utah Consolidated, and Utah Apex, of Bingham with a total of \$9,579,500; Daly Judge, Silver King Consolidated and Silver King Coalition, of Park City, with \$697,500; La Cygne, of Panguitch, with \$345,000, the Horn Silver of Beaver County with \$200,000, and the California of Big Cottonwood, with \$125,000.

Electric power is supplied by the Pacific Gas & Electric Co., the fifth largest concern of its kind in the United States, to the mining industry. It is the largest of its kind financial year (1915-16) to \$6,071,000. It is a combined \$59,126 over that of the previous year, its highest expansion in mining operations.

RECENT PATENTS

1,185,502. PROCESS OF TREATING ORES. Royal S. Handy, Kellogg, Idaho. Filed Oct. 28, 1911.

1. The process of treating sulfid ores containing lead which comprises roasting the ores, extracting the lead sulfate with an aqueous solution of sodium chlorid, extracting other metal constituents with an aqueous solution of iron chlorid, and recovering the lead and other metal constituents from such solutions.

1,186,306. PROCESS OF EXTRACTING METALS FROM THEIR ORES. William E. Greenawalt, Denver, Colo. Filed May 7, 1912.

A process which consists in dissolving copper from its ores with an acid solvent; applying hydrogen sulfid to the resulting copper solution to precipitate the copper and regenerate acid; separating the regenerated acid solution from the sulfid precipitate and returning it to the ore to dissolve more copper; treating the sulfid precipitate to recover the copper and elemental sulfur; treating the elemental sulfur to convert it into a precipitant, and then applying the precipitant so produced to precipitate the copper dissolved by the regenerated acid solution.

1,185,995. PROCESS OF TREATMENT OF ANODE-SLIMES AND SIMILAR MATERIALS. Francis C. Ryan, Hammond, Ind., assignor to one-half to United States Metals Refining Company, Chicago, N. J., a Corporation of New Jersey. Filed Feb. 24, 1911.

1. The method of treating mineral bearing material containing arsenic, selenium, gold, silver, copper and the like comprising roasting the slime with alkali carbonate, leaching with water, filtering to eliminate the arsenic and selenium,

and roasting the residue in the presence of sulfuric acid to sulfate the silver and copper for separation from the insoluble gold.

2. The method of treating mineral bearing material containing arsenic, selenium, gold, silver, copper and the like, comprising roasting the slime with sodium carbonate at a temperature which will complete the reaction of the materials before the mass sinters, leaching the sintered mass, filtering to remove arsenic and selenium, and roasting the residue in an oxidizing roast in the presence of sulfuric acid to sulfate the silver and copper, and separating the gold from the silver and copper.

1,186,104. FURNACE. William M. Kelly, Anaconda, Mont. Filed Dec. 18, 1915.

1. A metallurgical furnace comprising two reverberatory furnaces disposed back to back and in longitudinal axial alignment, the same forming a single treatment chamber arched across the longitudinal axis of the chamber, a central transversely disposed waste flue leading from and spanning said chamber, and means on the longitudinal axis at each end of the chamber for firing the furnace.

1,188,237. RECOVERING NOXIOUS AND OTHER MATERIALS FROM SMELTER-FUMES. Clarence Barrett, Salt Lake City, Utah, assignor of one-half to George Morrow, Salt Lake City, Utah. Filed Jan. 15, 1915.

1. The process of treating smelter fumes for the elimination of sulfur dioxide therefrom and the recovery of volatile metallic values, consisting in subjecting the smelter fumes on their passage from the furnace to the atmosphere to the action of a solution of bisulfid of an alkali or alkaline earth metal, thereby converting sulfur dioxide contained in the fumes into a soluble salt by the alkali contained in the solution, and also precipitating the soluble metal combinations in the fumes in the

form of insoluble salts of the metals and collecting such insoluble metallic salts separately from the solution.

1,188,794. TAILING-SAMPLER. Charles L. Lawton, Hancock, Mich. Filed May 19, 1915.

1. In combination, a launder for transporting material by liquid, and fluid pressure means operated by a fluid other than the liquid by which the material is transported for automatically taking and elevating samples of the material at predetermined intervals.

2. In combination, a launder for transporting material, suction means movable transversely of the launder for automatically taking and elevating samples of the material, and means for moving the suction means back and forth with reference to the launder.

1,186,709. DOUBLE-ACTING GRINDING PAN-MILL AND AMALGAMATOR. Charles Davey Tregoning, Grass Valley, Cal. Filed Oct. 28, 1915.

1. In an ore pulverizing machine the combination of an ore receiving pan, a bed plate mounted in the bottom thereof, grinding disks mounted to revolve flatwise on said bed plate, a central gear arranged therein, a plurality of gears mounted on and fixed to said disks and surrounding and meshing with said central gear, and means for rotating said central gear.

1,191,053. PROCESS OF CONCENTRATING METALLIC ORES BY FLOTATION. Homer T. Varyan, Toledo, Ohio. Filed Mar. 29, 1916.

1. The process of concentrating metallic ores which consists in agitating the ores in comminuted form in a mixture of water, oil and a suitable resinate, and then, by flotation, recovering the froth thus produced together with its accompanying metallic particles.

3. The process of concentrating metallic ores which consists in agitating the ores in comminuted form in water to which is added a mixture consisting of sixty-five per cent. oil and thirty-five per cent. resinate of soda, petroleum emulsifying upward of fifty per cent. of the whole, and then by flotation recovering the froth thus produced together with its accompanying metallic particles.

1,190,401. BALL-MILL. Ernest S. Gregor, Anderson, Ind. Filed Nov. 18, 1915.

1. The combination with a tumbling barrel rotatable about a fixed axis and having a crushing compartment provided respectively with intake and discharge openings for the material disposed about said axis, a pulley adapted to be charged from the exterior and provided with an axial tubular member discharging the material to be crushed into the compartment aforesaid, a stationary holder for the crushing bodies provided with a discharge opening and a ball-feed tube leading from said opening and discharging into the tubular member aforesaid.

1,190,466. APPARATUS FOR SEPARATING MATERIALS OF DIFFERENT SPECIFIC GRAVITIES. Charles Schifferle, San Francisco, Cal., assignor to The Yuba Construction Company, San Francisco, Cal., a Corporation of California. Filed May 18, 1915.

1. An apparatus of the character described, comprising a rotatable annular casing, means for introducing fluid into said casing to fill the same, an annular pocket formed in the inner wall of said casing and a lip on the casing extending into said pocket, the lip being spaced from the wall of the pocket to permit fluid to flow from the casing into the pocket.

1,190,224. APPARATUS FOR THE SEPARATION OF OIL, SAND AND WATER RAISED IN DREDGING GRAVEL. Leon De la De De la Paul Armand Dronard, Rouen, France. Filed Apr. 1915. Serial No. 687,922. Renewed Feb. 11, 1916.

A separator of the character described, comprising a vertical cylindrical casing which forms the bottom of the separator, a vertical shaft passing down to the bottom of the bowl, several vertical disposed walls which are provided with hinged doors, and form the walls of an annular compartment concentric with one of which is open to permit the oil to pass thereat, a stream of dredged sand, gravel and water, to be introduced through which the dried sand passes, to the bottom and out through a discharge pipe, off the side of the separator, and water flowing through the walls from the bottom of the separator.

Concentrates

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

MINE-WATER usually contains fine sand or grit in suspension. Engineers in South Africa, who have examined microscopically the grit in the water from Rand mines, find that the particles possess sharp corners that prove destructive to pump-valves and piping. The rock mined there is quartz.

HAULAGE in mines by compressed-air locomotives with storage-tanks is 3 cents per ton cheaper than by horses, mainly due to less labor, according to Raoul Green in a paper for the Canadian Mining Institute. The cost of supplies and depreciation are about the same in each case. Compressed air permits of from two to three times more ore being handled than by horses.

LOW-GRADE lead ore is mined in south-eastern Missouri. The average lead content is about 3%. Comparing this with low-grade copper ore, such as the 1% ore of Michigan, it is seen that the grade varies inversely as the price. That is, lead is ordinarily sold for 4 or 5c. per lb., while copper sells for 12 to 15c. per lb., or three times as much. Inversely, 3% lead ore and 1% copper ore are about the lowest grades mined.

DIAMOND-DRILLING costs are low in the lead-mining field of south-east Missouri. They average only 75c. per foot, varying usually from 60c. to \$1. Of a cost of 75c., about 25c. would be paid for labor, 25c. for diamonds, 10c. for fuel, and 15c. for repairing and miscellaneous items. These low costs are due to the consistently regular structure of the limestone, which is free from flint, and to the excellent labor and cheap fuel available. Drilling in the region is active at this time.

THE GOLD-SCHEELEITE ore of the Golden Point mine, at Maerua, in the South Island of New Zealand, is higher in gold when the tungsten-content is low, and the reverse. A chart, covering 1906 to 1913, when the average content of 41,435 tons was \$2.88 gold per ton and 0.66% scheelite, shows this peculiarity of the ore to a marked degree, except in 1911-'12. Exceptions to this rule are sometimes evident when 50% WO_3 specimens have free gold adhering to them.

SHOOTING of wells with dynamite, which the California State Mining Bureau has recommended as an experiment with a view of increasing production from the shale in the Santa Maria field, is giving encouraging results on the Western Union property where well No. 41 was shot. Strings of torpedoes 50 ft. long, and carrying 300 lb. of gelatin were used. Six shots were set-off. The well was dry before shooting, and during the subsequent cleaning out and intermittent pumping is said to have

produced from 50 to 75 bbl. of oil per day. It is planned to try the experiment at several other wells. The Santa Maria field is one of the few in California where the ground stands up well enough to require or even permit shooting.

AN AUTOMATIC electric hoist is giving satisfaction at the Inspiration mine in Arizona. A particular feature is that the motor is so fully controlled automatically that the hoist is started and stopped with a minimum of assistance from men. The reduction of labor in loading by an automatic system at the foot of the shaft also decreases the cost of operation. All the ore is raised from one level, which is 630 ft. deep; from 10,000 to 14,000 tons is hoisted per 14 hours. There are two vertical shafts a short distance apart, with two electric hoists of Nordberg type. A motor-generator set eliminates peak-loads. Each hoist is driven by a 580-hp. direct-current motor through a flexible coupling and Falk gear.

ECONOMY in mill supplies has become imperative owing to the increase of cost, due to the War. We read with interest in the report of the Redjang-Lebong company, operating in Sumatra, that during 1915 the manager had been able to economize on the most expensive item, cyanide, by thickening the slime introduced into the treatment plant and only using enough cyanide to get the gold and silver into solution. It was then found, that while an efficient precipitation could be maintained in the zinc-boxes under steady working conditions, it became necessary to increase gradually the strength of the solution in order to maintain the precipitation under the intermittent working conditions prevailing. As an alternative to increasing the strength of the working solutions so as to maintain the precipitation, the inert zinc could be removed from the boxes, but this also was at an enhanced cost due to the greatly increased price of zinc and the difficulty of obtaining sulphuric acid.

ATMOSPHERES that are deficient in oxygen begin to affect men when the amount of oxygen is about as low as that affecting canaries and mice. Canaries are slightly more susceptible to want of oxygen than are mice. In mixtures of air and nitrogen containing only 7.6 to 7.8% oxygen, canaries show pronounced distress. When the oxygen-content is about 7%, mice show considerable distress, and a man is in grave danger of dying; hence canaries and mice should not be used by exploring parties in mines to show when men unequipped with breathing helmets should retreat because the atmosphere is low in oxygen, according to G. A. Burrell and G. G. Oberfell of the U. S. Bureau of Mines. Mice and canaries, especially the latter, are chiefly of value for indicating to exploring parties the presence of dangerous proportions of carbon monoxide. In an atmosphere in which oil-fed lamps will not burn, an exploring party should not depend on canaries for further guidance, but should use breathing apparatus in advancing into the atmosphere.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

BUTTE, MONTANA

MINES OF THE EASTERN SECTION.—ANACONDA, NORTH BUTTE, BUTTE-DULUTH, TUOLUMNE, BUTTE GREAT FALLS, AND DAVIS-DAILY OPERATIONS.

There is great activity in all parts of the Butte district. The Northern Pacific will build a spur into the eastern section that will provide shipping facilities for several working mines now dependent on haulage by teams. Among the mines that will be benefited by the new spur are the Tropic and Greenleaf of the Anaconda company, the Colusa-Leonard and Butte Main Range under option to the Tuolumne company, and the Butte-Duluth, Bullwhacker, and Butte & London. Almost every company here is deepening one or more of its shafts, and work is being pushed on a large tunnel that will penetrate the continental divide three miles east of Butte. All the producing mines are hoisting ore at full capacity, and development companies are having no difficulty in obtaining funds for exploration purposes.

It is rumored that the electrolytic zinc plant of the Anaconda company at Great Falls will not be in operation before October 1. The experimental plant at Anaconda is turning out 25 tons per day of high-grade spelter. Since July, 100,000 additional shares of the Butte Copper-Zinc Co. have been taken up under the Anaconda's option at \$1 per share. The shaft at the Emma mine will be sunk to the 1600-ft. level, and will be in a position to make large shipments of zinc ore when the Great Falls plant is ready to receive it. A contract has been let to sink the Nettie shaft from the 500 to the 1500-ft. level. This will be the first deep development in the western part of the district, and will be watched with great interest as it is expected to give some idea of the possibilities of the production of zinc and silver in the surrounding properties. The United Copper Securities Co. has filed an amended complaint under the Sherman law against the Anaconda in the United States District Court at New York. The United Copper Securities Co. has acquired the copper interests of Otto Heinze and company. It is alleged that the defendants tried to influence the Montana courts to deprive Heinze illegally of his interests in Butte mines. Another charge is that in 1897 the defendants set fire to Heinze's concentrator and smelter and shut the water off for 1½ hours while the plant was burning. Damages were estimated at over \$1,000,000, and under the law three-fold damages were asked.

The recent slump in the North Butte shares was not due to unfavorable developments underground. Fifteen hundred tons of ore is being hoisted daily, and during June 2,096,326 lb. of copper and 90,713 oz. of silver was recovered. This is an increase over the May production of about 100,000 lb. and 2000 oz. Drilling on various levels has developed high-grade ore that materially adds to the reserves, and will tend to increase the grade of shipments. The Granite Mountain shaft is down below the 3500-ft. level, and it will probably be sunk to 3700 ft. The lower levels are hot, and several connections are being made to provide better air. The dividend rate has been increased from \$2 to \$3 per share per year, and at the present rate of production and 25-c. copper, the company is making a net earning of about \$7 per share. The surplus will be used for the purchase of new properties and for the further development of claims that have not been thoroughly explored.

The mine and mill of the Butte-Duluth company were closed-down by Court action when the company failed to pay the

interest on bonds held by the Providence Securities Co. of Duluth. The indebtedness amounts to \$875,000. The bond issue is for \$500,000, and the balance is made up of liens for wages, lumber, and machinery. Foreclosure proceedings were started with the idea of dismantling the plant, and selling the machinery to satisfy the claims for wages and lumber. The bond-holders, through their committee, filed a suit in intervention that held-up the foreclosure and sale of machinery. The high price of sulphuric acid for leaching makes it impossible for the receiver to operate the property at a profit. Efforts were made to obtain acid from the Anaconda company, but its output is at present limited to 100 tons per day, all of which is required for the operation of its own leaching plant. The Butte-Duluth was one of the pioneers in leaching in this country.

The Tuolumne company will sink the Colusa-Leonard shaft from the 800 to the 1600-ft. level, and cross-cut at that depth to the side-lines of the property, a total distance of 1800 ft. For the doing of this work the Tuolumne company will receive

PART OF EASTERN BUTTE.

51% of the shares of the Syndicate Copper Co., the holding company of which is the Colusa-Leonard. Each 80 ft. of shaft-sinking will be considered 1% of the total work to be done. One-half of the stock so earned will be paid to the Tuolumne at the end of each 60-day period, the balance when the work is completed, which is stipulated must be before May 22, 1919. The Colusa-Leonard is in the eastern part of the Butte district, near the Tropic mine of the Anaconda company. No work has been done on the property since 1907, but until that time development had progressed with encouraging results. The Tuolumne has taken an option on 1,000,000 of the 1,500,000 shares of the Butte Main Range Copper Mining Co., the average price being 65c. per share. Under the terms of the agreement \$10,000 per month is to be expended in development work. The shaft is now being enlarged and extended from the 700-ft. level to the surface. Good ore was encountered in the shaft, and it has been developed on the 500-ft. level, where it is reported to average 90 coppers. This ore will be extracted as soon as repairs to the shaft are completed. About 70 tons of copper ore is being shipped per day from the Tuolumne claim. Work is being hurried in a raise to connect the 200-ft. with the 2100-ft. level, to improve ventilation on the lower levels. It is then proposed to sink a winze in the less active

from 2600 ft., and if developments are favorable the shaft will be sunk to the 2800-ft. level.

The cross-cut south from the shaft on the 500-ft. level of the Butte Great Falls has cut the Dewey vein. A heavy flow of water was encountered, stopping work until the water-level is lowered. The cross-cut is over 700 ft. long and cut two other veins which did not contain profitable ore. Many of the richest veins at Butte are not productive on the upper levels, and the company will explore its veins at greater depth. The plans include a new shaft near the Dewey vein, to be raised from the cross-cut to the surface, and then it will be sunk to the 1000-ft. level. Application will be made to list the stock on the Boston curb.

Davis-Daly is hoisting about 100 tons of copper ore through its Colorado shaft. This is being mined on the 1400, 1500, and 2500-ft. levels. The ore from the upper levels averages 2.5%, but at 2500 ft. a drift has been put in over 400 ft. in ore averaging 5% copper. With the new hoist that is now being placed in position the output can be increased considerably. The old hoist is only strong enough to pull from 1700 ft., and it is necessary to hoist to that level with a station engine. Lessees on the Colorado dump have been able to sort ore that contains 2.5% copper and some silver.

At the Butte & Superior No. 2 and 3 shafts are down 655 and 1400 ft., respectively. Steel is soon to arrive for the 132-ft. head-frames. The June output was 10,830 tons of zinc concentrate from 48,475 tons of ore.

Butte and Eastern capitalists are to supply money for sinking a 1000-ft. shaft on a claim in Meaderville, east of the Cambert and Leonard mines.

The Butte & Bacon Copper Co.'s stock and property has been transferred to the Great Butte Copper Co., a re-organization company. A 90-ft. head-frame and steam hoist are to be erected at the Calumet shaft. The new company has a working capital of \$180,000, and no debts.

SUTTER CREEK, CALIFORNIA

PROGRESS AT OLD EUREKA.—KEYSTONE'S HALF-YEAR.—PLYMOUTH HOIST.—MAGNESITE AND COPPER.

Grading has commenced at the old Eureka mine for the new steel head-frame and hoisting machinery to replace the temporary arrangement that has been used up to the present in unwatering the mine. A good double-drum hoist has been purchased, to be on the ground by the time the foundations are ready. Meanwhile the work of unwatering and repairing the old shaft continues, this being in first-class condition for 130 ft., with the water removed 20 ft. below that point. The next improvement contemplated is a large timber-shed and modern saw-mill, excavation for which is now under way.

The semi-annual report of the Keystone Mines Co. at Amador City, to July 1, has been published, and is interesting in showing how low a grade of ore can be profitably worked under conditions prevailing here. The 41,018 tons treated yielded only \$1.98 per ton. In spite of this the company has in its treasury \$10,000 more than it had six months ago, after paying for mining, milling, taxes, and overhead expenses. The half-year's product consists of gold bullion, \$16,533; concentrate, \$89,688; and base bullion, \$1606. Freight and smelter charges on 1450 tons of concentrate amounted to \$17,391. The ore was taken mostly from the 900, 1200, and 1400-ft. levels, each of which produced from 10,000 to 13,000 tons, while 5602 tons was hoisted from the 1000-ft. level. Work has been temporarily stopped at 900 ft., and nothing has been done for several months at 800 ft., but veins of fair value, ranging in width from 6 to 15 ft., are showing on the 1000, 1200, and 1400 ft. levels, north of the shaft. Connections have been completed by raises from 1200 to 700 ft., affording good ventilation and increasing the miners' safety. On the 1400-ft. level, at a point 150 ft. north of the main cross-cut, the vein formed

two branches. Drifts have been driven on each of these, the face of the east branch now being in low-grade ore at a point 420 ft. north of the shaft cross-cut; and the west branch, which has followed the vein formation for about 650 ft., has now 8 ft. of ore in the face. Preparations are now under way for cutting a shaft station and chute at 1800 ft., from which an east cross-cut will be driven to the vein. Although the Keystone mine has been operated almost continuously since its discovery in 1851, until now it has had no chance to prove its value in depth, the deepest workings until three years ago having been but 1400 ft., or 1572 ft. on the incline, much nearer the surface than its neighbors north and south. The present company extended the shaft 1000 ft., and considerable interest is taken in the results to be obtained in exploring this ground. B. Hoxie is foreman, and C. R. Downs of Sutter Creek is general manager of this well-known mine, which was until recent years owned by M. J. McDonald of San Francisco. During the six months just ended, the mill lost only 2 days and 50 minutes on account of repairs, clean-up, and shortage of power, and the fact that only 6 hours of this lost time was due to power being off speaks well for present electrical service rendered in this district, a contrast with a few years ago.

During the week there arrived at the Plymouth Consolidated one of the finest hoists on the Mother Lode. It is to be installed immediately in place of the present machinery, which has proved somewhat inadequate for present requirements.

There appears to be some prospect of large deposits of magnesite being worked in this vicinity in the near future. John Beecher of San Francisco has been in Jackson for a few days examining several properties. It is said that there are valuable deposits of this mineral here awaiting development.

At the Allen copper mine, formerly known as the Hayward mine, three miles east of Ione, the shaft is down 500 ft., and preparations are completed for stopping a large block of this ore. The vein is 5 ft. or more in width, and contains gold as well as copper of profitable value. Large reserves of this ore have been blocked-out, and regular shipments will soon be made. C. N. Johnson of Sutter Creek is managing this mine for the Allen Estate Company.

TORONTO, ONTARIO

FURTHER CONTROVERSY ON NICKEL.

A keen political controversy has arisen over the policy of the Canadian government regarding the exportation of nickel matte for refining in the United States. The question was before Parliament several times last session, strong fear being expressed that the product of the Sudbury mines, once in the hands of Americans, would find its way to Germany. At that time the strongest assurances were given that sufficient precautions had been taken under an agreement with the International Nickel Co. to render this an impossibility, and that the British government was entirely satisfied with the arrangements. It was further stated that the company would without delay erect and operate a refining plant in Canada of sufficient capacity to satisfy the nickel requirements of the British Empire. The agitation subsided, but has been suddenly revived in greater force than ever owing to the announcement that the German merchant submarine *Deutschland* has taken on board a quantity of nickel purchased in open market in the United States. This, it is contended, must be from Canadian mines, as the United States is almost wholly dependent on the Dominion for its nickel. The topic has been taken up by the Liberal party, and will undoubtedly be a prominent issue in the next election. The position of the Government is one of great difficulty. If it were to yield to the clamor for a total prohibition of the export of nickel, it would not only prevent the possibility of Germany getting any, but it would cut off the supply of the American manu-

facturers who are making munitions for the Allies, and the establishment of a Canadian refinery would, it is stated, require at least three years. So far the Government has shown no disposition to adopt any more stringent measures. It justifies its position on the ground that it has received renewed assurances that the Imperial authorities are perfectly satisfied with the precautions taken to keep Canadian nickel from falling into German hands, and that the *Deutschland's* cargo must have been obtained from some other source. Meanwhile the International Nickel Co.'s representatives are examining ground in Ontario with a view of selecting a site for the proposed Canadian branch. The Mines Department of Ontario contemplates establishing a nickel refinery as a Government undertaking, and is conducting a series of experiments with two new patent processes.

Profits of the International Nickel Co. during the second quarter of 1916 were \$3,305,574. Preferred shares received \$133,689 in dividends. The surplus is \$5,171,885, equal to 7.58% on common stock. Cash amounts to \$4,137,633.

The Porcupine-Crown mill is treating 140 tons daily. A winze below 500 ft. is down to a depth of 730 ft. Sinking is to be done to 800 feet.

The Hollinger Consolidated Gold Mines has issued a state-

A flotation plant is to be installed by the Dominion Reduction Co. Callow apparatus has been ordered.

The Kerr Lake output for June was 237,912 oz. of silver.

The Beaver Consolidated is cross-cutting at 1600 ft. to explore the lower contact.

At Chippawa the new nickel refining plant of the Canada Nickel Smelting & Refining Co. is almost completed. Power is supplied from Niagara.

During the first half of 1916 the Teniskaming company did 2080 ft. of development. The main shaft has reached a depth of 1180 ft., a working station having been cut at the 1150-ft. level. Sinking will be continued until the lower contact between the diabase and keewatin formations is reached, which exists at a depth of 1600 ft. from the surface. On the upper levels of the mine, work is progressing favorably and some high-grade ore is being extracted. Cash on hand amounts to \$170,219, and bullion in storage and in ore 502,288 ounces.

REPUBLIC, WASHINGTON

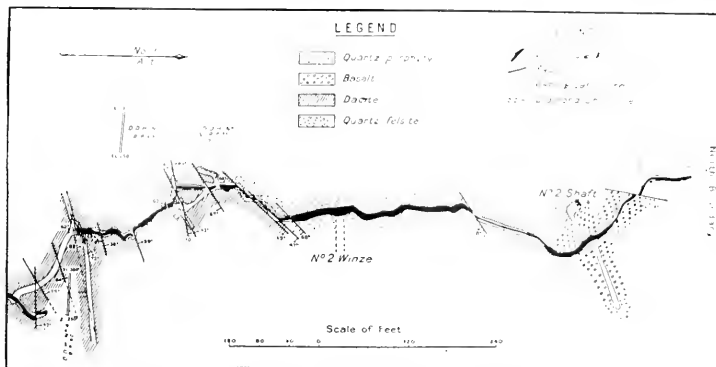

TRANSACTIONS OF IMPORTANCE TO THE DISTRICT.

It has been made public that the Day brothers, operating in Idaho and a smelter at Northport, have secured control of the Lone Pine, Pearl, and Surprise claims at Republic. Two instruments have been filed in the Ferry County auditor's office (1) a deed from George S. Bailey, trustee in bankruptcy for the Republic Mines Corporation, transferring the Lone Pine, Pearl, and Surprise claims, the final payment on which, amounting to \$82,000, was made on July 17; and (2) a mortgage on the same property to Jerome L. Day, of Wallace, Idaho, executed by A. B. Willard and A. J. Laughton, respectively as president and secretary of the Republic Consolidated Mines Corporation, to secure a loan of \$93,000, payable in one year and bearing interest. The provisions of the mortgage practically authorize the mortgagee to

direct the management of the property. The \$82,000 received by Mr. Bailey, as trustee in bankruptcy, will enable him to wind up the affairs of the Republic Mines Corporation during August and pay the creditors 100 cents on the dollar, and the shareholders of the Republic Consolidated Mines Corporation will receive a final dividend of about 50¢ per share.

In the Keller district work has been resumed in the Golden Crown mine adit with expectation of cutting the vein in less than 50 ft.—It is probable that the Addison mine, on Silver creek, will be soon reopened. If its good ore developed.—A shipment of ore is being dispatched from the Iron Creek mine on Iron creek.—The Manilla Creek bridge on the San Poil river is being repaired to enable the Illinois Mining Co. to ship ore. A new road from the mine to the main San Poil Valley road has been completed. The power flume to the Keller smelter is under repair. The Wall, Walla mine shaft is down 5 ft. with good copper ore in the bottom.

DURING the first half of 1916 tungsten production of the United States was equivalent to 3290 short tons of concentrate, averaging 60% WO₃ valued at \$917,000, according to the Geological Survey. This estimate is considered to be correct within 10%, rather under than over the true figures. Canada contributed 1505 tons, California, 84 tons, and Nevada, 161 tons. Eight other States reported.

PLAN OF THE THIRD LEVEL (300 FT.), PORCUPINE CROWN MINE, SHOWING GEOLOGY AND INTRICATE BLOCK AND STEP FAULTING TO WHICH THE VEIN HAS BEEN SUBJECTED.

ment for the period January 1 to June 16. From 8 levels, down to 1250 ft., there was hoisted 265,490 tons of ore. The mill treated 263,356 tons, averaging \$8.80 per ton. Mining cost \$2.631 and milling \$9.20c per ton. The mill is soon to be treating 1900 tons daily.

Faulting is much less at 700 and 1000 ft. depth in the McIntyre mine than in the upper workings.

The Tough-Oakes mill is treating 125 tons daily. Twenty-one drills are working underground.

During June the Schumacher yielded 4000 tons of \$5.94 ore, with \$8793 profit. The company has issued its first report, covering October, 1915, to June 30, 1916. The mill treated 30,120 tons, averaging \$5.42 per ton, at a cost of \$4.48, now \$3.87. The profit was \$31,933. Ore reserves are 64,900 tons worth \$6 per ton. A new shaft is to be sunk for extensive exploration.

The West Dome company has decided to sink a 4-compartment shaft in the centre of the property. Considerable work is under way.

The Vipond's June yield was \$37,600 from 10,185 tons of ore, at a cost of \$4.45 per ton. At 500 ft. in the mine the ore-shoot is 160 ft. long.

With a capital of \$2,000,000 the Augarita company has commenced operations in the Dome area of Porcupine. A contract has been let for diamond-drilling. W. G. Barney is manager.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

ANCHORAGE

For the railroad the Alaskan Engineering Commission has let contracts totaling \$112,000, for grading and ties in the Matanuska, Turnagain Arm, and Talkeetna districts. The last-named centre is reported to be busy, having 300 people engaged in mining and farming.

The territory adjacent to Anchorage is considered to offer inducement to capital for mining enterprises. Some properties are partly and others wholly undeveloped. Fifty-six miles from Anchorage the Crow Creek Mining Co. is employing 42 men at its hydraulic plant on Crow creek, a tributary of Glacier, which empties into Turnagain Arm, above Anchorage.

It is probable that Seward will receive its first 1000 tons of coal from Matanuska this summer, judging by the progress in railway construction.

CHISANA

The Chisana-White River district is described by S. R. Capps in Bulletin 630 of the U. S. Geological Survey. Gold was found on Bonanza creek in 1913. The whole area is strongly glaciated. During the last retreat of the glaciers the melting ice left morainal material throughout the district. Large deposits of outwash gravels were laid down and are still accumulating in the valleys of the glacier-fed streams. Talus, peat, muck, and some volcanic ash, as well as normal stream deposits, make up the post-glacial materials in the areas that are not now receiving glacial and glacio-fluvial deposits. The productive gold-placer gravels of the Chisana district are found within a small area, nearly all the gravels that have been profitably mined lying within a circle 5 miles diameter. Bonanza, Little Eldorado, and Skookum creeks have produced most of the gold mined. The short mining season, comprising only 90 to 100 days, and the remoteness of the district from lines of transportation combine to make mining expensive. Gold has been mined actively, however, and the total production of the district up to and including the year 1914, was probably not far short of \$300,000.

JUKEAU

Gold production of the mines on Douglas island were as following during June:

	Alaska Mexican	Alaska Treadwell	Alaska United
Stamps dropping	120	540	300

FAIRBANKS

In his report for the second quarter, the mine inspector, W. T. Maloney, states that the number of underground placer workings in the Fairbanks district has materially decreased, but several rich spots have been struck on many of the creeks, which will bring the average yield up to that of last year. It is expected that the output from the Fairbanks and Tolovana region will exceed that of last year on account of the increased production from Tolovana. Lode operations at Fairbanks

this summer have been confined to antimony mining, and over 1000 tons of ore will be shipped. Of the 10 quartz mills, only one is working, and that intermittently. Several small parties are working on tungsten lodes. Ott and partners shipped 1600 lb. of ore by parcel post in March, but it was delayed in delivery until June, when the price had dropped from \$65 to \$25 per unit.

ARIZONA

GILA COUNTY

On July 26 fire destroyed a considerable portion of the town of Miami.

MARICOPA COUNTY

A winze below the 400-ft. level of the Harqua Hala Bonanza mine, idle for years, has opened ore carrying 4.9% of copper and \$35.20 gold per ton. This property has a large past production.

MOHAVE COUNTY (OATMAN)

(Special Correspondence.)—There is a rumor current of a project to build a railroad into Oatman to connect with the Santa Fe at Topock. At the head of this enterprise is E. R. Hibbard, of Chicago, who is a brother of a Santa Fe official. Also mentioned in connection with the enterprise is Fred Schader, who made the original survey of the Santa Fe company across the desert into Los Angeles. Plans are not complete, but it is stated that the road is to come into Oatman from Topock by the way of the Old Trail. Then it may go north from Oatman, across the Colorado river, through El Dorado canyon, into Searchlight and the north to connect with the Salt Lake route.

Oatman, July 24.

Water from the Tom Reed cyanide-plant residue was recently drunk by 14 burros, resulting in their death. It would be an expensive matter for the company to impound or divert the residue.

YUMA COUNTY

The U. S. Geological Survey has issued as Bulletin 620-C, a report on the gold deposits near Quartzite, by E. L. Jones. This report is based on information obtained by the author while he was classifying the lands in the Colorado River Indian Reservation. The area discussed includes the southern part of the reservation and the region extending eastward from the reservation to the Plomosa mountains. The history of placer mining in this region is rather interesting, and dates back to 1862, when Pauline Weaver was trapping along the Colorado river and at times would stray off into the mountains on prospecting trips for gold. The Indians, with whom he was on friendly terms, gave him some nuggets and, after Weaver had organized a party from Yuma, conducted him to the source of the gold. The party picked up \$8000 in nuggets within a short time, but had to return to Yuma, 150 miles distant, for provisions. A rush from points in southern California and Arizona immediately started for these placers, and within a short time hundreds of miners were prospecting the country around the original location. Water had either to be hauled to the diggings from La Paz or obtained in small quantities from a near-by tank, and it is said that the water hauled from La Paz brought \$5 per gallon during the rush period. It is estimated that \$1,000,000 was recovered in the first year, and as much more in each following year until 1868. Since that time the production probably has been comparatively small.

The gold particles or nuggets ranged in value from 5c. to \$10, although \$20 and \$40 pieces were not uncommon, and the largest piece taken out was valued at \$1160.

CALIFORNIA

BUTTE COUNTY

The Big Blue Lead mine near Bangor, 10 miles from Oroville, has been purchased by F. F. Ford and C. G. Fowler, of San Francisco and Alaska, respectively. The property is an old gravel mine, having a 2500-ft. adit, and has produced a large quantity of gold from the Blue Lead channel. Water for operating will be available in the fall. Other old mines in the district are the Catskill, Grove, Bishop, Raffus, and Turner, all past producers.

PLUMAS COUNTY

For the sum of \$35,000 the Tefft quartz mine at Claremont, 6 miles south of Quincy, has been sold to H. H. Kelly and partners. A 20-ton mill has been ordered.

SHASTA COUNTY

According to Wm. A. Kerr, vice-president of the First National Copper Co., through the 10-year contract which the Balakalala company has with the United States Smelting Co., dividends are at last possible. The first payment will be 25c., and others will follow as earned. The mine is now shipping 9000 tons of ore monthly to the Mammoth smelter, that averages 2.83% copper and \$1 in precious metals. On August 24, 1915, the Balakalala mine resumed shipments after a long idleness. Unable to use its own smelter on account of furnace troubles, this contract was arranged. From the commencement of shipments to the end of the financial year, on June 30 last, the company made net profits of \$175,000 from 76,000 tons of ore. The company spent \$25,000 in making necessary repairs incidental to resumption of operations, and did development equal to 33½c. per ton of ore mined. The management now plans to increase development for which it will set aside 50c. per ton of ore mined. This new work will be confined chiefly to diamond-drill operations.

On July 25 fire did considerable damage (\$50,000) to the town at the Mammoth copper mine, 3 miles from Kennett. The property was temporarily closed. The aerial tram terminal, store-house, machine-shop, and boarding-house were burned. The compressors and motors were saved.

Following the strike for more wages at the Mammoth mine, the Mountain Copper Co.'s men walked out at Keswick on July 25, demanding Mammoth wages.

The demands were granted later on in the week.

The Balakalala Copper Co. voluntarily raised wages equal to those recently granted to the Mammoth employees.

The Michigan claims on Bully hill are to be developed, money being secured by M. E. Dittmar.

TRULINE COUNTY

The Springfield Tunnel & Development Co. has ordered three more machine-drills and will extend its drainage-tunnel, to further develop the good gravel opened recently.

YUBA COUNTY

The B. A. C. mine at Brownville is to resume work on August 1. A new stamp-mill and cyanide plant has been erected.

* COLORADO

Coal mining in Colorado quickly recovered from the effects of the strike in 1913 and 1914, and, according to C. E. Leshner, of the U. S. Geological Survey, the production in 1915 was \$624,980 short tons, valued at \$13,599,264, an increase of 451,421 tons, or 5½% in quantity, as compared with 1914, although the total value in the two years was practically the same. There were no labor disturbances during 1915, and the supply was plentiful. The number of men employed increased

from 10,098 in 1914 and 12,372 in 1915, but the average number of days of work decreased from 243 to 191. The average daily output per man was 3.58 tons and the average yearly output was 698 tons, compared with 3.32 and 809 tons, respectively, in 1914.

The quantity of petroleum marketed from the areas of oil production in Colorado in 1915 amounted to 208,175 bbl., a decrease of 11,298 bbl., or 6%, from the corresponding output in 1914.

CHAFEE COUNTY

In the lower adit of the Mary Murphy mine in the Cave Basin district, 12 to 16 in. of rich copper-silver ore has been cut in formation 10 ft. wide, which is all milling ore worth \$20 per ton. Flotation is successfully applied at this mill.

LAKE COUNTY (LEADVILLE)

Of importance to the district is the cutting of the Pendery fault in the Alright mine on Poverty Flats, lessees encountering granite at a depth of 260 ft., making the fault over 2500 ft. farther north than had been suspected. The Alright, Jason, Coronado, and Northern mines, on the west side of the fault, will have to be deepened considerably before reaching the ore zone which was found at a depth of 260 to 300 ft. in the Hilschle and M. E. C. on the east side. This information was given in Leadville last week by S. Marshall Carlton.

Power-lines are being erected for the Bartlett silver mine in the Sugar Loaf area. Lessees have advanced the adit to a distance of 1600 ft., after which a winze was sunk, power being required to cope with the water, which has always been a trouble.

Pumps are being lowered to the bottom of the Down Town Penrose shaft. The present flow is 2800 gal. per minute.

SAQUACHE COUNTY

The Bonanza district is reported to be busier than for years, several mines that have been idle for a long time are being re-opened. One of these is the Rawleigh, owned by the A. S. & R. Co. The drainage-tunnel is being cleared out. Machinery is arriving for the St. Louis.

TELLER COUNTY (CHIEF CREEK)

During the second quarter of 1916 the Vindicator company shipped 14,877 tons of ore on company and 16,276 tons on lessees' account. Net earnings were \$185,000. The flotation plant below the Golden Cycle ore-house will be completed early in September. Development between No. 12 and 18 levels opened an orebody of better than average grade.

On the 1400-ft. level of the Dillon mine of the Granite company the ore-shoot is 550 ft. long. The June output of the mines on Battle mountain totaled 4000 tons. Lessees continue to do well.

IDAHO

CESTER COUNTY

The Lost Packer mine on Leon creek is employing about 70 men underground, at the mill, and smelter, for a summer campaign. Placer mining on the creek gives work to 60 men.

SHOSHONE COUNTY (COOK MOUNTAIN)

On August 5 the Caledonia Mining Co. of Wallace pays \$5 per share, equal to \$78450, 14½% dividends for 1916 total \$599450.

At the average price of its products for the past 10 years, namely, 45½c. for lead, 5677½c. for zinc, and 5784½c. for silver, the Interstate-Caledonia company at Nye-Moore is expected to be able to earn \$1,000,000 net per annum. The profit in May was \$90,717, with metals above these averages, but the enlarged mill will make an increased output.

The Success Mining Co., with headquarters at Wallace, is remodeling and enlarging its mill situated on Nin Mile canyon, 4 miles from Wallace. It is replacing 8-ton discs

crushers with Garfield rolls and building an additional flotation plant in which will be installed two 12-cell mechanical agitation machines, to be used as roughers and 16 cells as cleaners. The ore, which contains lead, silver, zinc, and magnetite, after a preliminary crushing, is jigged for lead concentrate in 14 jigs, also further concentrated by 17 Wilfley tables. The tailing will be sent to the flotation annex for treatment: the jig product is sent to the rolls to be crushed to 10 mm., then taken by belt-conveyor to a rotary dryer. This product is elevated and the magnetic iron is extracted by the magnets, four of which are installed at present. These machines have proved satisfactory. The capacity of the mill is 300 tons per day. The flotation department is expected to be completed by August 1. The medium to be used is creosote and pine-oil. In order to overcome as far as possible the discomfort and inconvenience caused by the dust incident to operation of the electro-magnetic separation, a settling-chamber is used, built of wood and adjoining the mill. The dust is collected and driven by blowers through 24-in. iron pipes to the settling-chamber, which is fitted with baffle-boards to lessen the air agitation, and hung with wire netting on old jig-screens which act as a settling adjunct. The operation of this settling-chamber in lieu of the bag-house so generally used seems to be nearly as effective and considerably less expensive to construct and operate. The dust saved in this manner is collected and shipped in bags to the smelter.

MISSOURI

JEFFERSON COUNTY

The St. Joseph Lead Co., at Herculanum, has just completed experiments with Dwight-Lloyd sintering-machines and roaster gases. A small Cottrell plant was used for the latter. Various types of electrodes were tried, best results being obtained with No. 12 pipes, 15 ft. long, using No. 10 jack-chains for electrodes. These experiments proved successful, making about 96% lead recovery from the gases. The company contemplates erection of a large 'treater' to deal with approximately 150,000 cu. ft. of gas per minute.

JOPLIN DISTRICT

The 1000-ton per 20 hours mill of Chapman Brothers & Long-acre, north of Cartersville, commenced work last week.

At Commerce, Oklahoma, over \$1000 of damage was done to the power-plant of the King Jack mine when the surface caved to a depth of 50 feet. The mill had a narrow escape, just being on the edge of the hole.

Production of the Missouri-Kansas-Oklahoma region was considerably curtailed last week due to the blading of a 13,000-hp. steam turbine of the Empire District Electric Co. being damaged. Westinghouse mechanics are busy with its repair. At its Riverton plant the company has 3 turbines. The district's output was 4610 tons of blende, 32 tons of calamine, and 918 tons of lead, averaging \$65, \$45, and \$70 per ton, respectively. The total value was \$367,653.

On August 1 the agreed two-year wage increases for 35,000 men in the Missouri, Kansas, Arkansas, and Oklahoma coal mines takes effect. The annual output of the region is 13,000,000 tons. The advances are from 2 to 5c. per ton.

On July 17 a large cave-in took place at 160 ft. depth in the Babcock mine, 4 miles north of Joplin. Four men were imprisoned, and rescue-work was soon under way. They were rescued after 40 hours.

MONTANA

FERGUS COUNTY

(Special Correspondence.)—Lessees at the Cumberland mine in the Judith mountains, George Weiglenda, A. Sellers, Gene Nelson, and Milo Skerro have recently discovered a large body of rich gold ore, 20 tons shipped to the smelter averaging \$115 per ton. Another car of similar quantity is now ready for shipment. The Cumberland was located by Pete Rosso 15

years ago, and is now chiefly owned by James Breen of Spokane, who built a cyanide mill there in 1910. About 35,000 tons of ore was treated, yielding \$275,000, when the known orebodies were exhausted, and in the last few years the mine has only been operated under lease. The vein is usually narrow, but where now being opened is 25 ft. wide. Enough ore is already developed to supply the mill for six months, and as the depth is only 220 ft., it seems probable that the orebody will continue for a considerable distance.

The near-by Spotted Horse now employs 40 men, producing \$12,000 to \$15,000 monthly, mostly from the 100-ton cyanide mill. Concentrate is also produced.—William C. Young has a lease on the McGinness mine, and is employing a small force, sufficient to keep the mill busy about half-time.—Julian Stuart has produced several carloads of lead-zinc ore from the War Eagle. This will be concentrated at the Maginness mill and shipped. The ore contains 7% zinc.—Development at the Gold Acres property at New Year has been resumed under new management after a brief shut-down. The company hopes to start the New Year cyanide mill soon.

The Barnes-King has resumed mining and milling at its North Moccasin property after a shut-down in June for repairs to its power plant. Complete clean-ups were not made from the 1645 tons treated.—The West Kendall property is being carefully examined, and if development now in progress continues favorable a mill will be built.

Drilling for oil is now in progress on a small dome between Swimming Woman and Careless creeks, south of the Big Snowy mountains. In the first well a considerable flow of gas and water was struck at a depth of 700 ft., which damaged the drilling machinery. Repairs have been made, and the well will be sunk much deeper in an effort to find oil.

Lewistown, July 14.

NEVADA

ESMERALDA COUNTY (GOLDFIELD)

Operations are now in progress at 20 properties in this district.—At the Goldfield Consolidated mill the first 500-ton flotation unit is at work.—At a depth of 350 ft. in the Sandstorm-Kendall the cross-cut has passed through the vein from which rich ore was once extracted by lessees.—Exploration at 700 ft. in the Kewanas is yielding promising results.—Work is being resumed at 800 ft. in the Oro.—A re-arrangement of pumps in the St. Ives shaft of the Merges company is to result in important economies for the Atlanta. From the 1750-ft. level the water will be pumped to 1325 ft., through a pipe to the Grizzly Bear shaft of the Goldfield Consolidated, thence by pumps to the surface.

NYE COUNTY (TONOPAH)

Last week the Tonopah mines produced 9217 tons of ore worth \$191,386. In June the Extension made a profit of \$51,726 from \$966 tons, yielding 156,336 oz. of bullion.

During its past year the West End Consolidated Mining Co. treated 56,976 tons of mixed ores, yielding 13,219 oz. of gold and 1,219,968 oz. of silver. Profit from all sources totaled \$270,416.

WHITE PINE COUNTY

For the second quarter of 1916 the Nevada Consolidated pays the county \$49,608 as taxes. During the period there was treated 1,114,821 tons of ore, averaging \$5.861 per ton. The net proceeds were \$3,975,011. Taxes are paid on 80% of the net proceeds.

The U. S. Tungsten Corporation pays \$440 as tax. It milled 2767 tons of ore worth \$38.86 per ton. The profit was \$35,177.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence.)—The Mogollon Mines Co. has arranged a change in its system of freight delivery from Silver

City. A transfer station, including oil-storage tanks, has been erected at Glenwood, 12 miles from Mogollon, where fuel-oil and other supplies are delivered there by truck, from whence they are hauled over the heavy mountain grades to Mogollon by teams. The other operators are still depending on teams or trucks for the entire trip of 80-odd miles. The company's Last Chance shaft is down 800 ft., and the mill is treating 800 tons weekly.

Material for the mile aerial tram of the Socorro company's Pacific mine is mostly delivered.

Both the Clifton and Eberle mines of the Oaks company are yielding good ore.

Mogollon, July 25.

TENNESSEE

KNOX COUNTY

At the Mascot mine of the American Zinc, Lead & Smelting Co. at Granby the mill is being dismantled to make way for a large plant.

POLK COUNTY

The Tennessee Copper Co.'s acid plant at Ducktown is again

in trouble, and acid production is reduced to a low point from the nominal of 750 tons daily. The new plant of 8500 tons monthly capacity is about complete, but has had delays.

UTAH

BEAVER COUNTY

Shipping ore is being developed from 700 to 1000 ft. in the Cedar Talsman in the Star district. The ores mined contain lead, silver, and zinc, about 40,000 tons assaying 10% lead and 14.5% zinc. Such ore is not desired by smelters, so the company is investigating treatment processes.

JUAB COUNTY

The Tintic sampler is handling 400 tons of ore daily. A shift has been suspended on account of light shipments to smelters.

SALT LAKE COUNTY

For the purpose of driving a long drainage and transportation tunnel from Pine canyon on the west side of the Oquirrh range, known as the Bingham West Mountain, to connect with the producing mines of Bingham, the Pine Canyon & Bingham Tunnel Co. has been incorporated with a capital of 1,500,000 shares at \$1 par value. J. B. Moreton is president, Richard Savage vice-president, Homer Benton second vice-president, Louis Levine secretary-treasurer, who, with Henry Jones, Arthur E. Moreton and Ray Van Cott, form the directorate. The work is to be started in the near future. According to those behind the project, the tunnel will pass through the largest patented mineral area in the district, and it is believed that the water met with will be a constant source of revenue to the company. The transportation of ores will also add to the earnings of the company. The haul from the portal will be 2½ miles to the International smelter. The tunnel will be the lowest one in the district. The claims owned by the company

extend east to the apex of the mountain, and are located along two north-east-south-west fissures. From the present tunnel there is 240,000 gal. of water flowing every 24 hours. The company owns 42 claims.

The Utah Ore Sampling Co. is to increase its capital to \$500,000 by issuing 100,000 \$1 shares. The plants are at Midvale, Park City, and Tintic.

WASHINGTON COUNTY

As little has been heard of the Goldstrike district for some time, it is interesting to hear that the Goldstrike Bonanza company has cut a rich gold-silver streak at a depth of 76 ft. on the incline. The shaft is in limestone. Work continues at the Virginia.

WASHINGTON

According to the *Spokane Review* of Spokane the following is a list of new mills in the North-west. Among the new mills already in operation are the following:

Highland-Surprise mine, Pine Creek district, Coeur d'Alene, treating zinc-lead ore, capacity 125 tons of ore daily. Hypocheek mine, Kingston, Idaho, silver-lead ore, 125 tons. Intermountain company, near Iron Mountain, Montana, silver-copper ore, 100 tons. Empire Copper Co., Little North Fork, near Enaville, Idaho, copper ore, 300 tons. Lead & Zinc Mines Co., Metaline, zinc ore, 125 tons. Galena Farm mine, Silverton, B. C., lead-zinc ore, 100 tons. Lucky Jim mine, leased plant at Rosebery, B. C., zinc ore, 60 to 75 tons.

The following plants are under construction and several of them are nearly ready to begin operations:

Ray-Jefferson mine, Carbon creek in the Coeur d'Alene, zinc-lead ore, 400 tons. Snowstorm Consolidated, Troy, Montana, lead-zinc ore, 400 tons. North Star-Triumph mine, near Hailey, Idaho, Federal Mining & Smelting company, zinc-lead ore, 200 tons. Mike Horse mine, near Helena, Montana, Oregon and Montana people, zinc-lead ore, 100 tons. Highland Valley, Ashcroft, B. C., copper ore, 125 tons. Brooklyn mine, Maxville, Montana, zinc-lead ore, 100 tons. Kaslo custom concentrator, to treat Lucky Jim and other zinc ore, 100 tons. Florence Silver company, Ainsworth, B. C., silver-lead ore, 200 tons. Deer Trail company, Cedar canyon, Stevens county, Washington, silver-lead ore, 100 tons. Idaho Continental company, near Port Hill, Idaho, lead-silver ore, 300 tons.

Among the plants whose construction has been authorized but not yet begun are:

Consolidated Interstate-Callahan company, Enaville, Idaho, zinc ore, 1200 tons. Tamarack & Custer company, Wallace, Idaho, silver-lead ore, 250 tons. Constitution company, Pine creek, Coeur d'Alene, zinc-lead ore, 100 tons.

CANADA

BRITISH COLUMBIA

According to reports received by the Mines Department the present rate of mineral production in this Province is over \$8,000,000, against \$23,000,000 in the record year, 1912. Coal mining especially is on a greatly increased scale.

Ore received at the T. A. L. smelter continue to grow, that for the third week in July 1916, 103 tons, a considerable increase.

It was rumored that as the Standard Silver-lead company, at Silverton marketed its product through Bee, Sandhime & Co. of New York, the Standard company would be affected by the firm's being blocked by England. This is not so, and the Standard can continue to sell as usual.

MEXICO

According to S. W. Felt of the U. S. & R. Co., mining and other conditions in this country are very different with no apparent relief in sight. Nothing is being done in the way of mining or ore reduction at the company's plants in Mexico at present. They have been turned over to the true Mexican men.

ployees. Heretofore the company has been sending food supplies to those parts of the country where the plants are situated, not only for employees but for all living in the vicinity of the plants. This has now become practically impossible due to the inability of the Carranza officials to guarantee the arrival of such shipments.

KOREA

The Seoul Mining Co., operating the Suan concession in Whang Hai province, Chosen, reports the following results for June:

Ore treated, tons	14,555
Mills ran, days, average	22
Bullion	\$ 25,105
Concentrates	92,552

Total recovery	\$117,657
Expenses	57,500

Operating profit

June was low in milling days, principally because of changes made at the Holkol 40-stamp mill. Beginning with June 10 half this mill only was run on ore from the Suan mine, which the mill has previously treated exclusively. The other half of the mill, after making some changes for the purpose, treated ore from the adjacent huge low-grade deposit of gold, copper, and tungsten, in order to determine practically the best method of extraction. This deposit is known as the Sotcarie. Half the Holkol mill was worked for 25 days on Suan ore and half for 19 days on Sotcarie ore, or an average of 22 days. Also owing to changes, the mill at Tul Mi Chung mine ran only a little under 23 days on its ore, hence the smaller results shown for June than for a few months previously. Extraction on the Suan ore was remarkably good, 91.5% gold and 86.5% copper. From 2150 tons of Sotcarie ore 8252 lb. of tungsten concentrate was recovered, presumably of an expected 50 to 60% grade, this besides a fair recovery of gold and copper contents. For the first milling this is considered satisfactory. Milling capacity at Tul Mi Chung is being rapidly raised, the record being 453 tons on June 6. They are not now amalgamating at Tul Mi Chung.

THE AMALGAMATED ZINC (DE BAVAY'S), LIMITED, in the half-year ended December 31, 1915 states that the flotation plant at Broken Hill, Australia, treated 161,943 tons of purchased tailing, yielding 48,195 tons of concentrate assaying 19.1% zinc, 5.8% lead, and 7.9 oz. silver; also 710 tons of concentrate containing 57% lead, 11.1% zinc, and 48.2 oz. silver per ton. There was shipped 65,934 tons of concentrate, part of which was from the previous period. Sales realized £385,552, of which £159,823 was spent in operation, payment of tailing, etc. The profit was £168,078. No. 16 dividend, of 72 cents per share, was paid on January 16, 1916, absorbing £75,000, making £550,000 to date.

The general manager, H. W. Gepp, is still in America in connection with sales of concentrate, and investigating electrolytic zinc processes.

Obituary

MATTHEW HENRY WALKER, a prominent citizen of Utah, who, with his brothers, was a pioneer in mining in that State, died from cancer at Salt Lake City, on July 28. He is survived by a widow, a son, and a daughter. Mr. Walker was connected with many mining companies, and the Walker Brothers bank in Salt Lake City is a well-known institution. He was a man of charitable instincts, and did many acts of kindness in a quiet way.

THE EDITOR would be grateful for photographic prints suitable for reproduction in this paper.

Personal

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

W. B. DENNIS has gone to New York.

E. A. JULIAN was in Anador county this week.

J. R. TYRRELL of Toronto is in British Columbia.

A. ROOS is mining copper near Organ, New Mexico.

LOUIS A. DECOTO is on his way back from Columbia.

DAVID KEITH of Salt Lake City was in town last week.

HERBERT C. WOOLMER has arrived in London from Moscow.

WILLIAM BRADEN has returned to New York from Chile.

WALDEMAR LINDGREN was in the Yellowstone Park during July.

JOHN D. KIRCHEN of Tonopah was in San Francisco this week.

V. F. STANLEY LOW has returned to London from South Africa.

E. H. COOK has returned to Los Angeles from Culiacan, Mexico.

GEORGE S. EMBURY has returned to Berkeley from Pachuca, Mexico.

O. B. PERRY has returned to New York from the Yukon goldfields.

FRED S. PORTER is now with the Canadian Klondyke Co. at Dawson.

CHARLES JANIN is on his way back from Dawson, Yukon Territory.

ARTHUR W. STEVENS has returned from Colorado to Piedmont, California.

W. A. CARLYLE has left London for Toronto, which he will make headquarters.

E. M. HAUG has joined the engineering staff of the Tonopah Extension Mining Company.

G. H. WOHLHAUPTER of Magna, Utah, is taking a holiday at Houghton, Michigan.

F. C. RORCK of Michican is now with the Consolidated Arizona Copper Co. at Humboldt.

L. G. E. BIGNELL has joined the sales department of the Colorado Iron Works Co. at Denver.

WILLET G. MILLER has been to Mount Lyell and Broken Hill, proceeding from Melbourne to New Caledonia on July 6.

HENRY G. WALKER has arrived here from Shanghai, having inspected mines in the Chinese province of Chekiang.

JOSEPH W. RICHARDS, professor of metallurgy in Lehigh University, was in Butte last week, on his way to the Pacific Coast.

ROBERT M. RAYMOND, professor of mining in Columbia University, has been in Michigan and is now at Butte. He is expected here next week.

ERNEST MARQUARD, who has been in China for some time, has joined the Associated Geological Engineers of Pittsburg, and is now in Oklahoma.

E. T. MELLOR has resigned from the Geological Survey of the Transvaal to accept a position as consulting geologist with the Rand Mines and Central Mining companies.

JNO. M. BAKER and HAMILTON W. BAKER have resigned as general manager and mine superintendent, respectively, of the Baker Mines Co. of Oregon, and are now at Denver.

MORRIS WEBBER has returned to the practice of his profession at New York. For the larger part of two years he served as an artillery officer in the British army, in France, Gallipoli, and Bulgaria, being twice wounded and finally discharged with honor.

THE METAL MARKET

METAL PRICES

San Francisco, August 1.

Antimony, cents per pound	15
Electrolytic copper, cents per pound	27.50
Pig lead, cents per pound	10.00-11.75
Platinum: soft metal, per ounce	\$65
Platinum: hard metal, 100% iridium, per ounce	\$69
Quicksilver: per flask of 75 lb.	\$89
Spelter, cents per pound	11
Tin, cents per pound	11
Zinc-dust, cents per pound	20

Rich deposits of platinum are reported to have been discovered recently on the River Vilna, near Irkutsk, in Siberia.

ORE PRICES

San Francisco, August 1.

Antimony: 50% product, per unit (1% or 20 lb.)	\$9.75
Chrome: 40% and over, f.o.b. cars California, per ton	13.00-16.00
Manganese: 50% product, f.o.b. cars California, ton	12.00-16.00
Magnesium: crude, per ton	7.00-9.00
Molybdenum: 50% and over, per pound	0.50-1.15
Tungsten: 60% WO ₃ per unit	20.00

The tungsten situation at Boulder, Colorado, is considered by J. G. Clark, of the Boulder Tungsten Production Co., to be better. His company is negotiating for a year's ore at \$25 per unit.

New York, July 26.

Antimony: A few sales of spot material is reported at \$1.25 to \$1.50 per unit.

Tungsten: French consumers continue to negotiate, but the buyers do not want to meet the market. The nominal quotation is \$27 to \$30 per unit. It is reported that production has been curtailed in several directions. It is a significant fact that high-speed tool-steel was scarce and eagerly sought a few months ago, while today the makers are looking for business, and likewise the sellers of ferro-tungsten.

EASTERN METAL MARKET

(By wire from New York.)

August 1.—Prompt copper is scarce; lead is stagnant, spelter is dull and easy.

COPPER

Prices of electrolytic in New York, in cents per pound.

The Ohio Copper Mining Co. of Utah is to be re-organized with a capital of \$5,000,000 new securities. The Bingham Central Railway is included. Foreclosure takes place on August 1. June outputs include 1,500,000 lb. by Arizona Copper, and 4,011,361 lb. by Granby Consolidated.

Greene-Cannara is operating on the basis of 5,000,000 lb. per month. A dividend of \$2 per share is payable on August 25. Utah Metal & Tunnel Co. is paying its initial dividend of 25¢ per share, on August 15. This amounts to \$225,000.

SILVER

Eastern Metal Market

New York, July 26.

Copper, zinc, and tin present a better aspect, and the entire market has not the forlorn appearance it had a week or two ago.

Copper has a better tone, and it is asserted that good buying will follow a reduction of a few points in producers' quotations. The metal in second-hands is gradually being absorbed.

In the past 10 days export buying of zinc has been heavy, and quotations have advanced both here and in London.

Future deliveries, and metal afloat, have been fairly active in the tin market, and the tone is the best for many months.

Lead continues to drag in the absence of War business, and the trade says that new sales can be expected only at lower prices. Buying probably would start at 6c., New York.

Antimony continues dull.

Aluminum is unchanged at 58 to 60 cents.

An idea of the extent to which steel has been in demand is afforded by the fact that the earnings of the United States Steel Corporation in the second quarter of this year amounted to \$1,000,000. In many products, particularly steel plates, the demand is unabated. Following the decline in zinc, the makers of galvanized iron and steel pipe have reduced their prices \$10 per ton. Sheets are easier also. Though not officially confirmed it is known that orders for shells valued at approximately \$60,000,000 are to be placed in this country by Great Britain's fiscal agent, J. P. Morgan & Co. Sizes ranging from 6 to 12 in. will be called for. Already prospective contractors are inquiring for the large lathes and other machine-tools needed to execute such work.

ZINC

The improvement noted last week, which was started by purchasing on the part of domestic galvanizers, at prices somewhat under 9c. (for spot), was followed by an excellent demand for foreign consumers. A large quantity of zinc has been sold for export, at prices ranging from 9c. New York, for spot, to 10.50c., the quotation of yesterday (July 25). It is not thought that the export-demand is entirely satisfied. The London market is strong; it was quoted yesterday at £60 against £18 a week ago, an advance of £12. It is not considered that zinc will again go to the high levels of early this year, when at one time 21.50c., was quoted, but the opinion is pretty general that it will not average much under 10 to 12c., from this time on. Of course, this is all more or less guesswork, but it does indicate what the trade would like to see. Domestic consumers assert they should get the metal at about 8c., spot delivery, but it is pointed out that, considering the higher cost of production now prevailing, this price would really be about equal to 5c. The galvanizers, though they bought heavily a few days ago, should do more, inasmuch as they are operating not to exceed 50% of capacity, and a few only 25 to 40%. The galvanized-sheet market is very dull, consumers waiting for lower prices. Now that zinc has taken a turn upward it is questionable if they will get them. Not only is the cost of zinc involved, there also is the high price of sheet bars from which the sheets are rolled. Prices for zinc, prevailing yesterday, were 10.50c., New York, for spot, 10.25c. for August, and 10c. for September. Exports in 26 days were large, amounting to 5648 tons. Sheet zinc is unchanged at 15c. for b. mill, carload lots, 8% off for cash.

LEAD

The market has continued dull and drooping. Today (July 26), lead can be obtained at 6.20c. New York, and 6c. St. Louis, but there is little or no business despite the fact that some large consumers are known to be disposed to buy. It can be reiterated that present prices cannot be maintained

unless there develops a large volume of export business. The A. S. & R. Co. continues to quote 6.50c., New York, and 6.42½c., St. Louis. It is believed that 6c. New York would start some action. Some authorities say that stocks are not accumulating, but others, equally as authoritative, say that production is exceeding consumption. The London market is slightly lower than a week ago, at £28 5s. (July 25). Exports, to the 26th, totaled 2126 tons.

COPPER

While the quotation for spot lots of electrolytic held by second-hands, and to some extent by the smaller producers, has been practically stationary at 25c., cash, New York, the market has a firmer tone and a more hopeful aspect generally. Inquiries have been more numerous, the re-sale metal is gradually being absorbed, and there is a pretty well-defined feeling that the big producers are trying to 'local' a level which would stir consumers to action for the later deliveries. It is recognized that 29.25c.—the public quotation of the large producers—is a nominal price that will attract no buyers. It is commonly expressed by the trade that somewhere around 24c. would be likely to win business. As already said, inquiry has been better in the past two or three days and re-sale prices have become firmer, and the holders are not over-anxious to sell. Some of them are asking up to 26c. for July delivery, and 25c. for September. Lake copper is nominal around 25.25c. cash, for spot delivery. The London market also shows renewed strength, although electrolytic there is unchanged at £122. Exports from July 1 to 26 totaled 28,917 tons. The export demand for spelter has been good in the past 10 days, and it has been expected that some of this betterment would be imparted to copper. The following comparative statement, prepared by Secretary Mayer of the Metal Exchange shows copper exports from the United States in six months of this year, compared with those of the same period in 1915, in long tons:

	1916	1915
United Kingdom	31,732	47,109
France	76,127	19,148
Holland	1,138	457
Italy	23,723	23,965
Denmark	898	1,050
Norway and Sweden	7,223	10,567
Russia	5,053	3,151
China and Japan	71	49
Sundries	1,978	1,031
Total	147,943	136,527

TIN

The week has been a fairly good one, and for the first time in many months the market has shown strength. The activity began on July 19 with purchasing of futures and tin afloat, followed again July 25 by another flurry for the same positions. Extensive sales were made on the basis of 38c. for spot Straits. More would have been done had not London advanced too rapidly. The London market for spot Straits yesterday was £167 against £164 10s. a week ago. There was afloat yesterday 2396 tons, and in the month 2955 tons arrived.

ANTIMONY

A few inquiries are before the market but they are not sufficient to change the trend of prices, and the metal is dull at 13.50 to 14c., duty paid. Antimony in bond has been sold at 11c. Needle antimony is nominally quoted at 9c. per lb., forward delivery.

Company Reports

TONOPAH EXTENSION MINING CO.

This Nevada company had a highly profitable period during the year ended March 31, 1916, when the net revenue was \$613,418, and the Murray vein was opened for a considerable size at a depth of 1540 ft. Reserves indicate at least 15 years' ore supply. According to the general manager, John G. Kirchen, development covered 13,967 ft., making 115,218 ft. to date.

The mill, which is being enlarged, treated 91,581 tons of ore, averaging 0.24 oz. gold and 24.93 oz. silver per ton, a decrease of metal-content. The extraction was 92.39%.

There was sold 20,575 oz. of gold and 2,106,518 oz. of silver for \$1,532,910. Costs totaled \$10,965 per ton, a decrease of 51.1c. Mining was \$4,614, treatment, \$4,478, and freight, refining, etc., 5.91c. Dividends absorbed \$306,613.

OURO PRETO GOLD MINES OF BRAZIL.

This English company operates in the province of Minas Geraes, Brazil. The interesting 72-page report of the superintendent, A. J. Bensusan, deals with the year 1915. Development in the Passagem mine totaled 5375 ft., a good increase. The secondary No. 3 shaft is down 4641 ft. on the incline. Some promising results were obtained, but no large orebodies were added to the reserves, which amount to 74,705 tons, a decrease of 37,973 tons. The 80-stamp mill crushed 85,400 tons of ore with 91.41% recovery; the cyanide works treated 6736 tons of concentrate with 88.71%, 63,206 tons of sand with 74.01%, and 11,630 tons of slime with 81.96% extraction. Sand treatment cost 14c., and slime 71c. per ton of material. Gold from all sources realized £120,592 (\$580,000), equal to \$6.78 per ton. Expenses in Brazil were \$6.10 per ton. The profit was £9545. Preference shareholders were paid £1221, or 10% per annum. The net balance is £5137.

The report includes figures in metres, kilometres, grams, milreis, pounds, shillings, and pence.

ST. JOHN DEL REY MINING CO.

The 68-page report of the superintendent, G. Chalmers, for the 85th annual meeting of this English company operating the Morro Velho mine in Brazil, contains a mass of detail from which the following is abstracted:

Horizon (level) 19, a vertical depth of 5526 ft. below the surface, was opened by a winze from No. 18 level, a distance of 304 ft. Good ore was cut at 242 ft. down. Development of the lode on No. 19 was quite satisfactory. Ore reserves are estimated at 788,439 tons, equal to 4 years for the mill. Ventilation as usual occupied considerable attention, the temperature on No. 19 being 107° F. The fan worked well throughout the period. There were 6 fatal accidents in the mine. There was no shortage of labor.

The mill crushed and treated 192,500 tons of ore, yielding 109,555 oz. of gold and silver bullion, equal to \$11.63 per ton. Several improvements were made to the plant.

The revenue was £479,236, less £284,004 for all charges and £27,156 for Brazilian State and Federal duties, etc. The working cost, with development, was \$6.94 per ton. Dividends paid amounted to £11,750 on preferred, and £54,627 on ordinary shares, including taxes. Investments were valued at £202,991 on February 29, 1916.

On account of rapid cutting of trees re-forestation has been studied, and many trees planted. Further additions are proposed for hydro-electric power. The average cost is 2.918 cents per hp.-day. The 8-kilometre electric tram from the mine to Raposos on the Central Railway worked well. The medical department attended to 24,655 patients.

OIL-FLOTATION PROCESSES. Patents relating to R. S. LEWIS and O. C. RALSTON. P. 56. Index. Bulletin 8 of Utah Engineering Experiment Station of University of Utah, in cooperation with the U. S. Bureau of Mines.

THE IDEAL MORTAR FOR BRICK MASONRY. The Hydrated Lime Bureau of the National Lime Manufacturers Association, Pittsburgh. P. 32. Ill. index. Discusses experiments made with various mortars. One composed of 50 lb. cement, 20 lb. hydrated lime, and 300 lb. sand gave greater strength than several containing a greater proportion of cement.

HEAVY TIMBER MILL CONSTRUCTION BUILDINGS. By C. E. PAUL. P. 66. Ill. index. Engineering Bureau, National Lumber Manufacturers Association, Chicago. Mill construction is here used in the restricted sense of timber construction under special recognized standards. The result should be a structure that is in many respects more fire-resisting than a poorly constructed steel building. The pamphlet discusses the design and construction of such buildings and gives a number of useful tables. While issued by an association of lumber manufacturers with the object of increasing the use of their product, the pamphlet can hardly be called trade literature in the ordinary and somewhat derogatory sense of the term.

THE THEORY AND PRACTICE OF MODERN FRAMING STRUCTURES. By J. B. JOHNSON, C. W. BRYAN, and F. E. TURNER. Ninth edition, rewritten by F. E. TURNER and W. S. KINNE. Part III. Design. P. 479. Ill. index. John Wiley & Sons, Inc., New York. For sale by *Mining and Scientific Press*, San Francisco. Price, \$4.

The latest edition of this standard work has been rewritten by one of the surviving authors in collaboration with W. S. KINNE. The general arrangement and the topics covered are, however, similar to the old work. The subject of columns has been treated at considerable length, both from the standpoint of experiment and of theory. Second stresses are considered with special reference to their influence upon design. The analysis of girder stresses is especially complete. The chapters on highway bridges, foot bridges, and mill construction are comparatively brief. A complete list of chapter headings is as follows: *Stresses in Structures, Working Conditions, Compression Members, Combined Tension and Bending Stresses, Riveted Joints, Plate Girders, Framed Structures, Design of a Pin Connected Railway Bridge, Riveted Truss Design of a Riveted Highway Bridge, and Steel Railway Bridges.* The appendices contain general information on steel railway bridges, a list of standard and non-standard unsymmetrical beams.

Industrial Notes

Information supplied by the manufacturers.

Beyer Barometric Condenser

The Ingersoll-Rand Company of 11 Broadway, New York, is now offering to the trade complete steam condensing plants for all service conditions. This equipment includes the Beyer barometric condenser, for which the company has secured the patent rights, Imperial duplex and Ingersoll-Rogler straight-line, reciprocating, dry vacuum-pumps and, where required, Cameron simplex and centrifugal pumps.

The Beyer condenser is of the counter-current type, in which air and cooling water flow in opposite directions. The steam inlet is at the bottom of the condensing vessel, the water inlet above, and the air removal opening at the top. The sheets of cooling water overflowing the pool at the inlet point meet the entering steam. The two are brought into intimate contact by conical baffle-plates assisting the water to absorb

and vapor at a comparatively low temperature, a distinct advantage as the reduced volume saves in vacuum pumpage horse-power. The steam inlet is of large diameter to secure low velocity, and is hooded in such a way as to discharge the steam into the centre of the condensing vessel. The air removal opening is also of ample area and is protected by a self-draining baffle and trap. This, it is said, positively prevents water being carried over into the vacuum pump. The hot waste water is discharged through the self-draining tail-pipe. This pipe straddles the hot-well and rigidly supports the condenser. The Imperial and Ingersoll-Rogler vacuum-pumps are of the manufacturer's standard type. When a water-pump is required to elevate cooling water to the condenser head, Cameron pumps are provided. These may be either reciprocating or centrifugal as desired. The Ingersoll-Rand Co., however, emphasizes the fact that, where the level of the cold-well is of sufficient height above the hot-well, the condenser will lift its own cooling water, dispensing entirely with a water-pump.

The manufacturer emphasizes the point that the vacuum and water pumps, being independently operated, can be regulated to suit varying water temperatures and conditions.

Commercial Paragraphs

Vulcan steel-frame electric hoists for mines are described by the HENDRIE & BOLTHOFF MANUFACTURING & SUPPLY Co. of Denver in an attractively arranged booklet. The 250-hp. machine has a capacity of 3700 ft. of rope.

Cemented gold-bearing gravel is difficult to treat and save the precious metal, so some method of disintegrating the gravel is necessary whereby the large boulders and pebbles, which are barren, are simply free, not crushed, and discarded, while the sand, etc., is available for washing. Many systems have been tried with varying success. The G. W. Price Pump & Engine Co. of San Francisco claims to have devised a cement-gravel mill that will give the desired result. The machine consists of a hexagonal drum, in which the gravel is disintegrated by rubbing against itself, and cleaning the boulders of adhering material with streams of water. The fine material passes through screens and sluices, where the gold is caught. The large stones are automatically discharged. A 6-ft. mill will treat from 6 to 15 tons per hour, using 12 hp., at a cost of 5.6 to 9.4 cents per ton, depending on circumstances.

If improvements are to be made in mining methods, the E. I. DU PONT DE NEMOURS & Co. of Wilmington, Delaware, considers that one should install and adopt the electric method of firing explosives instead of the old method of fuse and blasting cap. In most of the modern and up-to-date coal mines electric firing and the use of permissible explosives have been adopted. Few mines exist in which conditions could not be made more safe, and the protection of the property enhanced by the use of permissible explosives and electric firing. The U. S. Bureau of Mines reports that fatalities during 1903, directly traceable to explosives, were 0.339 per 1000 men employed; in 1914, 0.096 per 1000, a reduction of 72%. Much of the credit for this remarkable improvement is due to the use of permissible explosives and electric firing. When explosives are detonated electrically, the maximum execution is always assured. The blast cannot occur until the miner desires it and when everyone is in a safe place. As many holes can be fired at one time as desired, so that it is possible to use less explosives per ton of coal or ore than when fired by fuse and blasting caps. The cost of installation is low; a blasting-machine suitable for use in coal mines costs about \$10 and will last for years if properly cared for, while electric blasting caps cost little if any more than ordinary fuse and caps, and the cost of leading wire is small. The advantages and benefits gained greatly outweigh the small first cost of installation.

SECTION AND PHOTO OF ACTUAL INSTALLATION OF BEYER BAROMETRIC CONDENSER.

to its full capacity the latent heat of the steam. The non-condensable air liberated in the condensing action rises through the falling water to the removal point at the top, being cooled to practically the temperature of the incoming water. It is also to be noted that ample opportunity is given for the removal of the air-content of the water before it mixes with the steam. This, the manufacturer points out, not only facilitates the mixing process, but permits the removal of air

EDITORIAL

T. A. RICKARD, Editor

TWO fellowships, of \$500 each, in metallurgical research have been established in the University of Idaho by the mining men of that State. This is an example to our friends in other mining regions.

SAGE-BRUSH is one of those plentiful products of nature for which it would be desirable to find industrial use; our readers will therefore be interested to know that a flotation-oil is being distilled from sage-brush, and that experiments made at the School of Mines at Reno, Nevada, indicate that it is twice as effective per volume as an equal quantity of pine-oil.

DURING July several lives were lost in California by explosions attributed to oxy-acetylene apparatus. Enough evidence has been gathered by the Industrial Accident Commission to warn users that tanks containing oxygen made by the electrolytic method are likely to contain hydrogen, forming a dangerous mixture. Investigations are being continued.

HOW metal is consumed at the battle-front is suggested by figures given by Hilaire Belloc. According to him it is stated at Berlin that in taking Hill 304, commanding the approach to Verdun, 37 trainloads of 40 cars each of shells were used. He also states that the actual cost of the eight or ten million shells used at Verdun alone during the past five months of continuous fighting has been \$300,000,000.

THAT the mines exploiting disseminated copper have increased their production greatly is indicated by a comparison between the June output this year with that of June 1913.

	June 1916 Lb.	June 1913 Lb.
Utah Copper	17,877,432	11,637,949
Nevada Con.	8,651,772	6,344,863
Ray	6,598,594	4,392,612
Chino	7,243,618	3,876,523

These four comprise the so-called Jackling group. The other mines of the 'porphyry' type are increasing their production at a similar rate.

ST. JOHN DEL REY, the deepest metal mine in the world continues to do well. The bottom remains at 5826 feet vertically below the surface. The company has just issued its 85th annual report, from which it can be seen that the enterprise is of respectable age. During the year ended on February 29, 1916, the mine produced 192,500 tons of ore yielding \$2,280,644 worth of gold, or

\$11.84 per ton, earning a profit of \$771,518. Owing to the step-like succession of shafts and levels, the poor ventilation is an obstacle to deeper exploration. The temperature at the bottom is 104° F. Mr. George Chalmers, the veteran manager, intends to use a cooling and drying equipment for improving the air, expecting thereby to render conditions more comfortable for the miners underground.

CALUMET & HECLA is receiving honorable mention in the press in consequence of its semi-centenary. The changes in the yield and cost per ton of ore afford a good text for comment. At one time the yield of copper was 100 pounds per ton of ore; this declined to 20 pounds. Meanwhile the cost has been reduced from \$10 to \$2 per ton of ore, otherwise the mine would have been closed-down long ago. The Calumet & Hecla has done well, but it would have done much better if it had not stuck so long to a policy of secrecy in regard to its technical operations. Secrecy usually goes with unprogressiveness. The man or company that declines to give information is the one not to receive it. Our own observation proves to us that the management that refuses access to its mine, mill, or smelter is usually behind hand in its technical work. The three notoriously secretive mining companies, the Rio Tinto, Homestake, and Calumet & Hecla have gained nothing from such a policy.

MAGNESITE has depreciated suddenly. The principal producer of this mineral product in Tulare county, a company that has been contributing 80% of the Californian output, has been unable to renew its contracts with the American Refractories Company, the General Refractories Company, and other big consumers. The contracts were to have been renewed in July. Another company, also operating near Porterville, finds itself unable to find a market. The reason is that the product has been allowed to deteriorate, by increase of silica, to such a point that it became unsaleable. In one case an effort has been made to raise the average by buying higher-grade deposits and mixing their produce with the main supply, but even this improvement has proved unavailing in face of the unexpected importation of 20,000 tons of Greek magnesite, knocking the bottom out of the domestic market. Of course, prices have been abnormal recently. Crude magnesite used to be delivered at West Berkeley for \$2.50 per ton, allowing \$1.50 for mining and \$1 for freight. Calaine magnesite used to sell for \$15 in the East. Recently consumers at Pittsburgh and Joliet had to pay something like \$10 for calaine, the price for crude here being \$10. That is why

the European supply has been drawn upon, as was done when quicksilver was kited to an impossible price.

Then and Now

In this issue we discuss the difference in economic conditions governing mining on the Mother Lode in California as compared with thirty years ago. A similar comparison might be made for any other Western mining district, and, with minor differences, it would be equally suggestive. It happens that 1869 just includes the use of nitro-glycerine, which was first introduced, at the Hoosac tunnel, in 1867. The discovery of an absorbent for nitro-glycerine and the preparation of a neutral product, both of which we owe to Nobel, marked a distinct epoch in mining. Previously, owing to its excess of oxygen, which renders this explosive so effective without the aid of extraneous oxygen, it had been most unsafe to handle and had been the cause of a number of accidents almost ludicrous in their unexpectedness. Soon afterward came the power-drill, the Burleigh machine being used at the Hoosac tunnel in 1866 and at the Georgetown mines, Colorado, in 1870. It was gradually modified, increasing in strength and lightness until now it is handled by one man and employed advantageously even in a narrow stope. Where formerly a miner would do 6 to 8 feet of drill-holes in a shift and break $1\frac{1}{2}$ tons of ore, now with a machine-drill one man drills 35 feet of holes and breaks 7 tons per shift. Even in later years the improvement is remarkable. In the North Star mine, at Grass Valley, it required 80 men in the stopes to supply 40 stamps; now 20 men will make the same output of ore. Another example, among many, of the help given by machinery is the tool-sharpener. This simple device will cost \$1200 and last four years, so that allowing 5% on the original cost, it will cost \$1440 in four years. It does the work of six men, three pairs each consisting of a sharpener and his helper, at a cost of \$5.75 per pair, or \$17.25 per day or \$5175 per annum or \$20,700 in four years. The power required for a sharpener is only 50,000 cubic feet of air at 24 cents per 1000, or about \$1 per shift. Using this machine a pair of men will sharpen and temper 300 to 350 drills per shift; by hand a pair of men will sharpen 80 to 175 drills per shift. Again, to make a wider comparison: The labor of 40 men will cost \$36,000 per annum. Machinery that would do the work of 40 men may cost \$40,000; it will last 10 years and represent a cost, with interest, of \$60,000. But in 10 years the 40 men will have received \$360,000 in wages. This example would show a saving of \$200,000, less the cost of power, for the machinery. Apart from the actual saving, the use of machinery facilitates large-scale operations that not only lower the cost per ton but diminish the effect of vagaries in the richness and distribution of the ore. Extensive development carries a large mine through bad times, which compel a small mine either to shut-down or change ownership at intervals.

Speed of exploratory work is an important factor, de-

creasing the ratio of overhead expense and enabling new reserves to be opened up at a rate commensurate with the increased capacity of the mill. Where two or three feet was made in a cross-cut by hand, it is now practicable to advance 7 feet per shift by use of a power-drill. The speed of driving on a vein is fully twice what it was. Nevertheless, it is not wise to have too much ground open at any given time, owing to the cost of re-timbering. Along the Mother Lode, most drifts in the ore have to be re-timbered at least every six months. It is the best opinion that reserves enough to supply the mill for two years is a proper compromise between the cost of keeping the necessary workings open and the assurance of an adequate supply of ore.

Another point worthy of emphasis is the accurate sampling of ore in the mine, of pulp in the mill, and of tailing before it runs into the creek. When a superintendent is without accurate information on these matters he is not only pretty sure to be losing much of the metal but is trying laboriously to win, but he cannot check his operations at various stages so as to improve them; in short, he is unscientific. In the old days a grab-sample would be taken and the assay of it would become a tradition. For instance, old Thomas Price, 'Professor' as he was called, a well-known assayer twenty or thirty years ago, took a sample at a mine, still richly productive, and reported that the tailing assayed \$1 per ton, when the ore was yielding \$15 in the stamp-mill. That would be good work, indicating an extraction of 93%. For many years the Professor's dictum was accepted as correct. Finally, accurate sampling was introduced and proved that the tailing averaged \$2.25, after the grade of the ore had fallen. In those days the recognized method of sampling was to place a tin-can at the outflow and allow it to fill, while the water and slime ran away. This, of course, was a rough process of decantation, all the rich slime being carried away and the can filled with the heavy sand, usually the poorer part of the pulp. Another source of error was due to the fact that the millman, much occupied with his multifarious duties, would take a sample in a leisure moment, when the concentrators and other machines were all running sweetly, this being the very time when the loss in the tailing was at its minimum. In these matters we have learned a good deal, as also in cost-keeping and the general recognition that small items of expense become important cumulatively. As to the work underground, the best proof of our gain in economy and skill is afforded by the ability to treat profitably the filling from the old stopes. It used to be the custom to 'resue' or strip the vein, breaking the ore separately from its casing or wall-rock. This Cornish method has much to recommend it in narrow rich veins, but it was over-done. The 'old-timers' failed to get the stringers or 'feeders' in the wall-rock and they were unable to prevent the fine from mixing with the fill, so that in the end 'resuing' was, we venture to say, a wasteful method of mining. Nowadays, we stope the width required for a power-drill, breaking to the full size of the vein and its branches, and then sort out the waste both

underground and at the surface, finding this economical.

These are among the reasons why it is proving worth while to re-open some old mines, particularly in a district where intense mineralization makes it probable that new orebodies are likely to be found by diligent search and intelligent exploration. The Mother Lode is worthy of such ventures; it must be acknowledged. The Kennedy mine is now 3896 feet deep vertically and has been at work uninterruptedly for 31 years. Most of the other important mines have been re-opened more than once. The Plymouth, now so successfully operated by an English company, lay idle from 1888 to 1913. The Gwin, which Messrs. F. F. Thomas [and we pause a moment to record sorrowfully that this honorable engineer and good citizen has just died] and David McClure re-opened in 1894 and closed-down in 1908, is again to be resuscitated, we understand. During the last campaign of 14 years this mine yielded \$3,500,000 gross and \$1,000,000 profit, half of which was put into plant and purchase of adjoining ground. The richest mine on the Lode, the Argonaut, is 4350 feet deep on the dip, equal to 3900 feet vertical; a new hoisting engine has been placed recently on the 3900-ft. level and the shaft is to be sunk 4000 feet more, so say the owners, who have every reason to feel cheerful, the ore at the bottom averaging \$13 per ton. In 1915 Amador county passed Nevada county into first place as a producer of gold. The largest tonnage (17,000) came out of the Kennedy, this mine being only approached in bulk of output by the Plymouth, which produced 129,500 tons. The average yield in the county was \$4.76 tons, of which \$3.11 was won by amalgamation and \$1.65 by concentration, the concentrate averaging \$79.91 per ton. The mines of the Jackson-Sutter Creek district showed an average yield of \$5.51 per ton, indicating ore of considerably higher grade than in the mines northward, which reduced the average to \$4.76, as we have seen. And all this good work is being done unobtrusively—almost too quietly for the fame of the mining district—without the aid of any of those questionable practices that cling to share-dealings on a stock-exchange. The men controlling these mines are veterans, familiar with local conditions and not without acquaintance with districts farther afield; they deserve the success they have won, and we hope it may continue.

The Imponderables

On another page we give our readers an address delivered recently before the Colorado School of Mines by Mr. J. R. Finlay. What he says or writes is interesting, for he is an engineer that can think on his own account and express his ideas in convincing phrase. In this utterance, and in others made by him since the War began, he shows himself much impressed by the material aspect of civilization, by the coal and iron, by the machinery and industrial energies of a nation. The estimation of progress in terms of tonnage and of human ability in units of horse-power appeals, we presume, to

the engineering instinct. From that it is a logical step to the admiration for tonnage and horse-power as produced or applied by large combinations of men and machinery, and to the placing of a bouquet at the feet of the big corporations. A good case can be made for this view of mundane affairs and we acknowledge that Mr. Finlay presents his opinions in an interesting manner. But he does not persuade us in the least. Making every allowance for the stimulation of the arts of life by the great industrial developments of the last half-century or more, we deny the argument that humanity has progressed over slag-dumps or culm-piles. England, Germany, and the United States may exhibit a coincidence of industrial wealth and advance in civilization, but it would be arrogant indeed to deny that peoples lacking the stimulus of material growth have played a notable part in the world's intellectual progress. It is only necessary to refer to one race—the Hebrew—that for centuries was denied industrial participation, that was harried and harassed, and yet out of poverty and degradation produced countless master-spirits of Art. France is an industrial country, she has valuable resources in coal and iron, but who would dare to measure her contribution to the spiritual advancement of humanity by her output of coke or steel? The history of European civilization thunders a denial. The chronicle of our own day, of these calamitous years, proves that the crass materialism fed on coal and iron has stultified Christianity and sent civilization to the shambles. From Cambridge, Massachusetts, not Chicago, Illinois, nor Oxford, nor Manchester, have we drawn our inspirations. The great universities may no longer be found in Egypt or Greece, but the argument of a vanished learning is like that of the man who remarked on the providential fact that the big rivers were near the big towns. Universities are placed near the centres of population. We like the man who prefers to use a steam-shovel rather than a mob of shovellers, for he shows intelligence, but we demur to the suggestion that such a man "is likely to have valuable ideas about Art, Literature, Science, etc." That type of man, unfortunately, is only too likely to read the tape in preference to Shakespeare and to prefer watching the ticker to looking at a Corot. It is a sad fact that devotion to machinery is not usually compatible with love for the things that have no price. Darwin's love for music was atrophied by the grinding of generalizations. The delight in the machine and the absorption in the work of producing the raw materials of civilization are not necessarily favorable to "Art, Literature, Science, and Government;" on the contrary, we see plenty of signs that they deaden the finer perceptions and the greater preoccupations. The doctrine that concentration of commerce and congestion of trade are identical with human welfare and national progress is worth tracking at this time when our country is in the midst of an orgy of industrial success with the great cities across the Atlantic are spending themselves unreservedly in a fight for great principles. We need to be reminded that not the ton of coal or iron, nor even the dollar, is the only

unit that enters into the account between man and his destiny. Thuxley, speaking at the opening of Johns Hopkins University, in 1876, said: "I cannot say that I am in the slightest degree impressed by your bigness, or your material resources, as such. Size is not grandeur, and territory does not make a nation. The great issue, about which hangs a true sublimity, and the terror of overhanging fate, is: What are you going to do with all these things? What is to be the end to which these are to be the means?" That great philosopher would not have been impressed by the number of employees in the service of the corporations that served Mr. Finlay's convenience between New York and Denver. He would regret having to trouble so many! Nor would the multifarious activities of the Guggenheim brothers evoke his admiring astonishment, although he would respect the technical skill exhibited in their mining and metallurgical operations. The great expositor of the evolution theory would question the necessity for agglomerating undertakings in Chile with others in Alaska, and he would ask whether the consolidation of industrial enterprises had not progressed beyond the evolution of a super-man capable of controlling them efficiently. Assuredly he would have ridiculed the statistical theory that the output of coal and iron measured national greatness. No; the great imponderables outweigh them, and not even the heft of the sword shall change the judgment of the eternal scales. As engineers, we rejoice in technical achievement; we take our part in the exploitation of national resources, we recognize how much of material comfort and convenience has come to man from the digging of metal and the fashioning of machines; but we know how to observe, we have read history, we have imagination; let us then not be fooled into thinking that the making of munitions is as fine as the personal service in the trenches, that the lending of money compares with enlistment in a great cause, that the trade in copper is as splendid as the right hand of self-sacrifice.

The Burma Mines

In a recent issue we referred to the Burma Corporation, which owns the Bawdwin mines, in the Northern Shan States. Since then we have received the company's annual report, in which is recorded the latest estimate of ore reserves. It shows 2,300,000 tons containing 25.4 ounces of silver per ton, 27.5% lead, and 22.2% zinc, besides 733,000 tons of "anticipated additions" to which no definite assay-value can be assigned, making 3,033,000 altogether. A deduction of 5% in volume is made for vugs. Metallurgical tests indicate that two products can be made: (1) a lead concentrate comprising 39% of the weight of the ore and assaying 45 oz. silver, 55% lead, and 11% zinc, the recovery being 70% of the silver, 79% of the lead, and 24% of the zinc; (2) a zinc concentrate comprising 35% of the weight of the ore and assaying 15 oz. silver, 10% lead, and 45% zinc, with recoveries of 21, 13, and 68% respectively. The combined metal recoveries would be 91% of the

silver, 92% of the lead, and 92% of the zinc, but in concentrates, of course, not as refined metals. Such concentrates were "easily saleable" says the report, "before the War, and on pre-war contracts would yield good profits." At present selected silver-lead ore is being concentrated on the spot, the product being treated in the company's smelter at Nanttu, 13 miles from the mines, pending further arrangements. The capacity of the refinery has been increased to 1100 tons per month. Meanwhile further tests and arrangements are pending for the disposal of the major produce of the mine, the zinc-lead ore. In the article in which we mentioned the Burma Corporation as a source of zinc, we referred to the purchase of the Swansea Vale smelter, in South Wales, by a syndicate headed by the group controlling the Zinc Corporation. We learn now, through *The Mining Magazine*, that the purchaser is Mr. R. Tilden Smith, one of the principal shareholders in the Burma enterprise. Nor will the Zinc Corporation spend a large sum of money on another smelter, as was announced in London recently. The zinc-smelter business is as hopelessly muddled now as it was nearly two years ago, the British authorities having failed to appreciate the importance of the matter, despite the urgent representations of the producers and consumers of spelter in the Empire.

Since the above was written we have read the account of the recent annual meeting of the Burma Corporation, as reported in the London financial press. On that occasion Mr. Theodore J. Hoover, who is chairman of the Technical Committee, brought his estimate of ore up to date and stated that 3,500,000 tons had been proved above the Tiger Tunnel, which is the main drainage adit. He described "an inner core of most phenomenal richness," this core being 850 feet long by 45 feet wide and containing 600,000 tons of ore assaying 40% lead, 23% zinc, and 37 ounces silver per ton, so that it consists of 63% solid metal. His forecast of profit is \$15 per ton, to be won at the rate of \$5,000,000 per annum. Any money needed for capital expenditure can be obtained from the rich core by extracting 40,000 tons annually for a year or two. The enterprise started by smelting an old accumulation of slag made by the Chinese; now the smelter at Nanttu is treating the old slag and the ore from the mine in equal proportions, and the tendency will be to increase steadily the proportion of mine product and to decrease that from the old smelter-dumps. Investigations are being made preparatory to building a zinc smelter in England, with a subsidiary plant in India, where coal and labor are cheap. The German contracts, under which some of the zinc ore was sold before the War, have been cancelled by order of the British Government, so that the company is free to make new arrangements. In many respects the technical operations of the Burma Corporation are of unusual interest and we hope to keep our readers advised concerning them. Mr. H. C. Hoover, the chairman of the company, has resigned, temporarily, owing to his absorption in the work of the Belgian Relief Commission; but he continues to be a member of the board.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and scientific questions relating to mining and metallurgy. The Editor welcomes expressions of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Prospecting

The Editor:

Sir—In your issue for July 22 appears a letter from Harold French headed 'Prospecting: A Suggestion.' Mr. French offers a good example of a plausible theory that would not work in practice.

In the first place it would be impossible to get experienced prospectors to work under the conditions proposed. Such men rightly have a high opinion of their

abilities and would insist on receiving at least a half-interest in all valuable discoveries.

There is no region in the United States where a mine may be found by superficial prospecting. In other words, it is extremely unlikely that there are still any undiscovered visible outcrops of profitable ore on the public domain. The Siskiyou country mentioned by Mr. French as the goal of his hypothetical prospecting expedition is one of the least prospected regions because it is one of the most inaccessible. I spent three seasons prospecting in that region and am more or less familiar with it. Every summer

IRREGULAR POCKETS IN MAD MULE MINE, SISKIYOU COUNTY.

there are many prospectors scattered over the Siskiyou hills singly and in parties of two or more. Most of them are experienced men and their work is quite thorough. They have long since ceased to look for outcropping orebodies and now use the methods of the pocket-hunter. By the way, the finding of orebodies by pocket-methods is a science in itself and one not taught in the schools.

Any experienced prospector will see that the blocking out of 150,000 tons of ore during the month of August or any other month on a raw prospect is an absurdity.

After the discovery of a promising outcrop a large amount of time and often much money must be spent in order to find the proper place to begin blocking out operations. Also, more often than not, the promising outcrop does not fulfill its promises and we are forced to begin the search over again. \$5000 would make a mine of some prospects. It took over \$1,000,000 to bring the Calumet & Hecla to the dividend stage. No two are alike.

In my opinion an 'exploration syndicate' could be made a success, but it would be necessary to operate on a much bigger scale than that proposed by Mr. French. A capital of \$1,000,000 or more would be necessary and it should be understood that the majority of the prospects thought promising enough to justify the expenditure of money for development work will prove to be worthless. However, one real mine will offset a number of failures.

JOHN B. PLATTS.

Oatman, July 24.

[We have added the sketches (after the U. S. G. S.) of the pockets of ore found in the Mad Mule mine, which is in Siskiyou county, as illustrating Mr. Platts' remarks.—EDITOR.]

Flotation on Silver Ore

The Editor:

Sir—Last fall we started up a 100-ton flotation plant on the Monitor-Belmont mines here, at Belmont, in Nye county, Nevada. I believe this was the first oil flotation plant in Nevada for the treatment of silver ores. The ore is crushed through 70-mesh screens and pumped to a Dorr thickener. From there it flows to the flotation-machine. At present we are using 12 cells of the Minerals Separation type with sub-aeration, followed by a pneumatic machine somewhat on the Callow order. Our extraction and ratio of concentration are now quite satisfactory, but we have had one experience that, I believe, you will like to hear, particularly since we learn that others are having the same difficulty, and that is in the taking care of the concentrate after it is made.

We installed a continuous filter to drain our concentrate. The original installation provided for taking the froth over the lip of the feed and mud line without the introduction of air from a blower and then the filter handled the froth nicely, and later when all the froth came from the pneumatic machine the filter had no difficulty, but after we added the sub-aeration feature we

found it an impossibility to utilize the filter. It had an ample capacity too—all we asked of it—but the makers only claimed that it was intended to take a product that was at least 50% solid and preferably 60%, while ours with sub-aeration was about 10% solid. We put in two cones, hoping to thicken it sufficiently before putting it into the filter, but a considerable portion of the concentrate would stick to the sides of the cones and later would come down with a rush, plugging them up. Then it would take considerable time to start them flowing again, and the cones were generally running over the sides and also taking back a very rich product to the Dorr thickener and on through the system again, and we were losing a considerable quantity of concentrates on the floor, so we conceived the following idea, in desperation:

We built six tanks, each 4 by 4 by 16 ft. long, in the lower part of the mill. These were built of the lumber we had on hand, 2-in. planks, which we tongued and grooved and kept full of water for a few days. We built these in two series of three tanks each and we took the froth direct to Tank No. 1 and allowed the water and froth to run over the top into tank No. 2 and from that to tank No. 3. We put the small 1½-in. pump, which had been doing service on the filter, to pumping the overflow from tank No. 3 back into the Dorr thickener. We ran on these tanks until No. 1 was solid and No. 2 nearly so, No. 3 being only partly full. Then we changed the delivery to tank No. 1 of the second series and repeated, and emptied the first series. We made small doors in the bottom of the end through which we shoveled the concentrate and from there to the drying-plate. This concentrate contains 25 to 30% moisture and if we had the elevation we would have taken this product to the filter before putting it on the drying-plate, as it was then in the proper condition. We have discontinued the use of the filter.

The light froth builds up several feet above the height of these tanks, but we add boards to hold it in, and in due time it settles back into the tank. We are now having no difficulty in taking care of our product and the loss in so doing is negligible.

LLOYD G. NELSON.

Belmont, Nevada, June 30.

[This letter is interesting. It exemplifies the use of a good machine under conditions for which it was not designed and for which it was never intended. Obviously, the employment of a filter on a pulp containing only 10% solid is incorrect. We venture to suggest that experience would point to the placing of a thickener before the filter, instead of the settling-box system, which is an old device that has been discarded ever since mechanical thickeners became available. Moreover, the lack of fall below the tanks and the consequent want of elevation for a filter is a reflection on the design of the mill, not on the filter. Indeed, the description fails entirely to reflect on the usefulness of the continuous filter; it simply illustrates how such usefulness can be spoiled by a misconception of the proper function of a specialized machine, which has proved itself invaluable wherever a flotation product needs to be drained. The obvious course to take, when

it was found that sufficient fall was not available to carry the thickened pulp from the settling-tanks, would have been either to lower the level of the filter or elevate the pulp to the filter rather than send a thickened pulp carrying some 30% of moisture to the drying-floor. Mechanical filtration is more economical than dewatering with the aid of fuel.—EDITOR.]

A Traveler's Library

The Editor:

Sir—Could you, through an article in your widely read columns, inaugurate a discussion as to the most suitable library of general technical reference books for an engineer on foreign service? The text-books used during a college course are generally so many and of such size and weight that their transportation in these lands of mule and 'pit-pan' travel becomes an engineering problem in itself. Therefore emphasis should be laid upon compactness and number.

San Salvador, July 16.

SUBSCRIBER.

[We shall be glad to receive suggestions.—EDITOR.]

FOREIGN TRADE has developed so rapidly that attention has been directed to the great ports of the world. Before the War introduced unusual conditions, the six greatest ports in point of annual total value of foreign commerce were New York, Hamburg, London, Liverpool, Rotterdam, and Antwerp, ranging between \$1,000,000,000 and \$2,000,000,000 each in imports and exports per annum. Of secondary importance are Hull, Bremen, Marseilles, Havre, Trieste, Buenos Aires, Calcutta, and Bombay, each having a foreign trade between \$300,000,000 and \$700,000,000. Ranking next in importance are Manchester, Southampton, Glasgow, Dunkirk, Genoa, New Orleans, Galveston, Boston, Montreal, Santos, Rio de Janeiro, Shanghai, Yokohama, Kobe, Singapore, Alexandria, Sydney, Melbourne, Bordeaux, Philadelphia, Baltimore, San Francisco, and Havana. It is worthy of note that the whole foreign trade of Japan, even with the added impetus of War conditions, is scarcely more than a quarter of that of the single city of New York, Liverpool, or London.

Four American banks, all in New York, are now included in the list of the 20 great banks of the world, having each over \$200,000,000 in deposits. First in the list is the Imperial Bank of Russia with deposits of \$760,405,000; second is the Bank of England with almost the same amount. Then follow three other London banks, and sixth is the National City bank of New York, which in 1913 was 17th and the only American bank in the list. The three other American banks now included are Guaranty Trust Co., National Bank of Commerce, and the Bankers Trust Co. The Bank of Montreal is also listed. In the list for 1913 were the Hongkong & Shanghai Banking Corporation, Bank of Spain, and Banco de la Nacion Argentina. No Japanese bank is in the list.

The Problem of Efficiency

By James R. Finlay

*If I were to try to do what I fear you may expect me to do, namely, to discuss the various technical improvements in the art of mining which have come forward in the past few years, I could do little more than recite a long list of them. Moreover, I should probably be trying to talk about something that your graduating students know better than I do. Nevertheless I shall try to be technical. Perhaps I may succeed in drawing your attention to some of the most practical of subjects that your graduates will face at once and will continue to face all their lives.

This school is engaged in the business of preparing young men for the industrial career known as mining. It occurs to me that it may be interesting, even valuable, to pass in review some of the major conditions under which an industrial career is carried on. I wish to call your attention to the proportion of things in the world's affairs: how important power-driven industry is, how it gives rise to industrial corporations, and how large a part these corporations play in our every-day life and particularly in the mining business, and how success in the business of mining depends so largely upon knowing how to deal with them. And through all this I should like to convey the impression that after all there is nothing so valuable as a good mind properly trained.

The essence of modern industry is just this: A man equipped with his muscles and his brain develops about one-twelfth of a horse-power and he can use it for perhaps eight hours per day. You pay him for doing this, say, \$3. The same amount of mechanical energy can be purchased in industrial communities for less than one cent. Therefore, it is perfectly plain that in these days when you hire a man you are paying not particularly for his muscular energy, because if you were buying energy you could buy four hundred times as much in another form for the price you pay your laborer. You pay your laborer for using his brain to direct not only his own muscular energy but the mechanical energy, so vastly cheap, that can be supplied to him through machines.

In mining I see nothing to separate it widely from other forms of industry. The mere fact that the miner digs material out of the crust of the earth does not make his methods essentially different from those of the man who makes use of materials already lying on the surface. The problem of mining industry today is the problem of applying the greatest amount of mechanical energy that can be used effectively by a unit of human energy.

Having stated the thing this way, we come at once to the important fact that this problem is the problem of corporate effort and not of individual effort. The energy

from a power-plant cannot possibly be utilized by a single person; nor can it be built, or the machines in it manufactured, by individuals. Power-driven industry even in its crudest form implies collective effort. To take an example from the history of mining, when the gold-hunters first came to Colorado, or more certainly when they first went to California, they used no machinery. They used tools, picks, shovels, pans, rockers, and wheelbarrows, but not steam engines. So long as they worked that way each man could work effectively by himself; and in the placer days of California nothing was heard of corporations. The gold was produced by a nameless swarm of independent workers. But when they began to operate lode mines, in which steam-engines must be employed for pumping, hoisting, and stamping, that was an enterprise calling for a number of employees; it took collective effort, it produced the corporation immediately. The same kind of illustration can be found in any other industry that uses mechanical power. Thus in transportation, so long as it was a question merely of pack-animals or wagons, the individual unit was nearly, if not quite, as effective as a corporate unit. One man with his team could haul as cheaply as a company managing ten men with ten teams. Not so when they came to use steam, or any other form of power for transportation. Your locomotive needs a roadbed and rails; it must have cars. The thing needed collective effort and capital.

It is well to remember that if this country had remained in the industrial status of the time when the Declaration of Independence was made we might by now have had our population of a hundred million people, but practically the only corporations we would have known about would have been the Central Government, the 48 States, innumerable counties and cities, and also religious corporations, churches, and colleges. But under those conditions it would have taken a month's hard travel to go from Denver to New York, you would have been lucky here in Colorado to get an answer to a letter sent to New York in two months, while as it is you can get one easily in a week; indeed, if you are in a big hurry you can talk to New York by telephone in 15 minutes.

One essential thing in bringing about this change, besides the invention of appliances, has been the development of a new kind of corporation, the business or industrial company, to supplement the governmental, and educational corporations that had been known before. It cannot be said truthfully that these business corporations are entirely the result of the use of mechanical power, for trading, financing, and other commercial companies have been known for many hundred

*Address before the Colorado School of Mines at Golden

years; but it is quite true to say that their great importance as a factor in daily life comes from the use of mechanical power.

In this way it seems to me that the development of mechanical industry is greatly widening the exercise of human intelligence. There is exercise for great ability in directing the innumerable business corporations, manufacturing concerns, transportation concerns, mining concerns, in every one of which there is a distinct reward for the man who can make a little better mixture of the ingredients of efficiency; but it is not only the managers, but practically all of the employees who have a widened scope for the exercise of their brains. Anyone who exercises power beyond those of his own body is using his intelligence more than he otherwise would. Thus, the man who drives a locomotive must have experience and knowledge above that of the man who simply walks. These are facts that no intelligent man can deny. I believe it to be an absolute fact that those regions and those races which have developed industry best have developed mentality best. They have developed industry because they have had the mentality; and while this is true, I think it is also true that a prosperous industry attracts good human material to it. A man does not think highly who is content with stupid unproductive labor. Of course, people without high intelligence may move a lot of coal and iron; but which is the more intelligent man, he who insists on moving coal and iron with his bare hands or he who does it with a steam-shovel? I think the question needs no answer. Moreover, I fully believe that the man who wishes to use a steam-shovel and make it work is the more likely to have valuable ideas about Art, Literature, Science, and the Government, or whatever manifestation of mentality is desired.

The mechanical industries that have sprung up in the United States and Europe have produced great prosperity and this prosperity has helped to develop not only the natives of these regions, but it has induced ambitions and intelligent people to migrate to those areas from other parts of the world.

The proof of the pudding is in the eating! Where are the seats of learning today? Where do you go to learn Art, Literature, Science, Music—anything you can think of? You do not any longer go to Italy or to Greece or to Egypt to learn these things. You go to the great industrial countries, the United States, England, Germany, and to those portions of France that are more particularly industrial. It should be pointed out that power-driven machinery is made of metals, particularly of iron, and driven by coal. It is natural, therefore, that industry should be most active in those regions where iron can be successfully manufactured. This is the case to a greater extent than most people realize. The areas of the world in which iron is successfully manufactured are relatively small. There are two great areas: A belt bordering the Great Lakes from the upper Mississippi to the Atlantic coast in the neighborhood of New York, and another belt extending from the Irish Sea across

England and into Germany, including Belgium and northern France. These are the areas in which at least 90% of the iron of the world is manufactured and a very large percentage of the machinery operated. And what do you find there? You find the six greatest cities of the world, one after the other.

The more you examine into it the more you will be impressed by the fact that these areas have become the market and the clearing-house of the world's commerce, the centres to which all other metals, including gold, must go to be utilized. You will notice further that these areas hold the reins of power in human affairs. You find there the financial, political, military, intellectual, social, and artistic capitals of the modern world, to which not only every article of trade, but human intelligence itself, goes for cultivation and development.

It seems to me worth while to lay stress on this situation because a great many people would like to believe what I have said is not all true. There are those who would have us believe that we are focussing our attention too much on the pursuit of industry and wealth; that by so doing we miss the chance to develop higher and better things. You will be told, for instance, that the growth of corporations is turning us into a nation of employees, another name for slaves; that after all only a few can be leaders, the rest must be followers; that the opportunities for personal initiative and independent action are being swallowed up in a flood of corporation routine which will end by giving human life the monotony of machine-made goods. There may be some truth in this, but whether it is true or not, I believe that we are in an age where the tendency is irresistibly in the direction of the continued growth of corporations. Whether we like it or not, we shall have to accept it. It is an element of common sense to accept the inevitable, not only with resignation but with cordiality.

But I do not look upon this development as undesirable. We are living in a great age, which will be called by future historians the age of the conquest of natural forces by the human mind. There was a similar age thousands of years ago in prehistoric times when men domesticated animals and plants; when they exchanged the free life of mere hunters for the exacting and settled life of agriculture and trade. By giving up a portion of their freedom those ancient people found that they were repaid by a great expansion of the possibilities of life. We are doing the same thing in a different way. The old hunter was persuaded to give up his freedom to wander in order to enjoy freedom from hunger. Our people are being persuaded to give up a portion of their freedom of individual effort and undergo the discipline of the collective effort, for the privilege of having a lot of things and of doing a lot of things which they could not have or do otherwise.

To illustrate how far the activities of corporations affect our daily life, I thought it would be interesting to find out how many people were employed by the corporations with which I would have to deal in coming from New York to Denver. I went through this simple

process: I received a telegram from Mr. Phillips, traveled over the Pennsylvania and Burlington railroads in Pullman cars, and upon arriving at Denver talked to Mr. Phillips over the telephone. I find that in order to do this I had to depend on corporations as follows:

The Western Union Telegraph Co. employs	40,000
Pennsylvania Railroad	225,000
Burlington, Northern Pacific, and Great Northern	100,000
Pullman Palace Car Co.	30,000
American Telephone & Telegraph Co.	150,000

A total of, say..... 551,000

If we add to these the United States Steel Corporation, which makes a good part of the rails, bridges, and cement for these structures, the Baldwin Locomotive Works and American Locomotive works, which build the engines, we should find that the corporate machinery we depend upon to make this trip would soon count up to a million employees—in eight concerns alone. The Steel Corporation alone is employing about 250,000.

In getting this information I secured the last annual reports of a number of these companies and I found in them a number of bits of information well worth knowing. For instance, I find that the Pennsylvania railroad has either as pensioners or employees 4300 men who have been in the service 40 years and upward. This is a good example of how these corporations affect people's lives. Another thing is interesting to mining people. The Pennsylvania handled last year 142,000,000 tons of freight, of which over 60%, nearly 86,000,000 tons, was the product of mines. To this we could add 8,500,000 tons of manufactured iron and steel, so that the total freight really coming from the mines amounts to nearly two-thirds of the total.

I find, moreover, that this concern is owned by 93,936 stockholders of whom 45,906, or nearly half, are women. Its funded debt amounts to \$728,353,615, held by about 100,000 bondholders. Its employees number about 225,000, so that altogether the number of people who depend partly or wholly upon this concern for their livelihood exceeds 400,000.

I think few of us realize on what a colossal scale these concerns are co-operative industries. They are owned literally by the public. There is no stockholder of the Pennsylvania who owns 2% of the stock. The board of directors and the officers, numbering in all about 90 men, are said to own altogether less than 5% of the stock.

Almost every one of these reports contains something of interest. In that of the American Telephone & Telegraph Co., I find this sentence: "The radius of dependable commercial speaking transmission has been very greatly increased, and it is now certain beyond any question that as fast as developed or potential business and social requirements indicate commercial practicability, every section of the country can be put in speaking transmission with every other section, and every subscriber to the Bell system will be able to speak to every other subscriber, regardless of distance." The report goes on to explain partly how this has been accomplished,

but I have no time to enter into that. The thing I am trying to bring out is the kind of efficiency these corporations are securing, and how the telephone as a mechanical device has been supplemented by far more intricate corporate device, human mechanism of 150,000 parts, in order to put the enormous convenience of this telephone at the service of the public. These concerns are not mining concerns, but we find the same thing going on in the mining business on fully as great a scale. The United States Steel Corporation is the greatest of industrial corporations and it is a mining and metallurgical concern.

It will be of more interest, perhaps, to take some note of the growth of mining corporations in the West. This hall bears the name of Guggenheim and this suggests discussion of a great mining and metallurgical concern that originated right in Colorado. Moreover, a brief inquiry into the rapid growth of the Guggenheim interests will serve as well as anything else to illustrate the forces that are causing that growth.

The group of enterprises operated by the Guggenheims makes as yet only a modest comparison in point of size with the great corporations I have mentioned. They employ only 35,000 to 40,000 men. The companies under their management are the American Smelting & Refining Co., the Federal Mining & Smelting Co., the Kennecott Copper Co., the Nevada Consolidated Copper Co., and the Chile Copper Co. I suppose there are other ramifying interests. Of these the largest industrial unit is the American Smelting & Refining Co., which in 1915 employed 15,500 men in the United States, and I understand about 10,000 in Mexico. I shall not take up your time by tracing the history of this company except to remind you that its present size is largely the result of consolidations made during two or three years from 1899 to 1901. Before that time the properties of which it now consists were divided among at least 20 separate companies. An immense amount of mining property and smelting property has been acquired by purchase or has been constructed by the consolidated company. As in the case of the Pennsylvania railroad, I wish to call your attention to the fact that the American Smelting & Refining Co. is owned, I believe, by about 15,000 stockholders. There is no dominating owner, or group of owners. The Guggenheim brothers only own a few percentages of the stock. They and their friends, however, continue to dominate the management, because that management is good and there is nobody among the stockholders to challenge it, not any feeling of discontent among the stockholders to make them wish to change the management.

This concern is beloved by many people who are competent to judge to be in the very front rank of efficient corporations. Its growth is built upon that efficiency. There is nothing in the least mysterious about it. The men at the head have breadth of view and the faculty of leadership that enables them to keep the company well equipped in three essentials, adequate finance, organization, and technical skill.

Magnesite Production and Markets

By Samuel H. Delbear

Magnesite from foreign countries was less available in 1915 than in the previous year. From the Austria-Hungarian deposits some shipments were received until March of last year. The Greek mines continued to export occasional cargoes to the United States, and doubtless would send more were it not for the scarcity of ships. The following gives imports that reached American ports from foreign countries, in short tons, being for the year 1915:

Austria-Hungary	52,086	Netherlands	3,554
Germany	722	England	129
Greece	4,437	Scotland	150
Denmark	103	Canada	948
Italy	710	Venezuela	508

These figures do not mean that all of the countries named are producers of magnesite. High prices in the United States caused re-shipment from some of these countries. Total imports into the United States during 1915 are reported as 63,348 tons of calcined and 18,731 tons of crude material. Prices rose during the latter part of the year. Imports of calcined magnesite decreased heavily, whereas nearly five times as much crude was imported as in 1914.

CALIFORNIA. The domestic production of magnesite in the United States during 1915 was 30,325 tons of crude, which includes 10,951 tons of calcined; as against 11,293 tons, estimated as crude during 1914. Production during 1916 will no doubt greatly exceed that of any former year. Because of the difficulty in securing imports, the demand for the Californian product has been active and many new mines are now shipping ore. Tulare county continues to be the most important source. The chief development in that region has been the re-opening of the deposits abandoned by the Tulare Mining Co., and purchased by the Porterville Magnesite Co., and the operation of a new mine of great promise adjoining that of the Tulare Mining Co. on the south fork of the Tule river, 14 miles north-east of Porterville. A 5-mile rail-extension has been made, and a tramway built, giving excellent transportation. The development of this mine was commenced by S. R. Coghlan and T. E. Frederick in the latter part of 1915, the mine being sold subsequently to R. D. Adams of the Lindsay Mining Co. Doyle & Smith have opened another new deposit in Frazier valley; so have Cook & Langley in the vicinity of Deer creek, where an excellent grade of ore is being mined. The California Magnesite Co. operated several leases in the Porterville district, and commenced the erection of a large calcining plant. Their work was later interrupted by litigation. Aside from the mines mentioned there are many smaller ones yielding one or more carloads per month. Shipments from

the Porterville district in May, 1916, totaled 127 carloads.

The Tulare Mining Co. continues to remain the largest producer in the State. All of the product from its Porterville mines is calcined. The company operates two shaft-kilns. It also made shipments of crude ore from its Napa county deposits.

In Sonoma county, the Sonoma Magnesite Co. com-

MAGNESITE VEIN OF LINDSAY MINING CO.

pleted a rotary calciner, and shipped some calcined material. This was hauled 14 miles to Guerneville, the projected narrow-gauge road having been completed recently.

The Refractory Magnesite Co. re-opened the old Creon deposits near Preston in Sonoma county, and shipped several hundred tons of crude ore, which was calcined at the plant of the Pacific Carbonic Gas Co., the carbon di-oxide content being recovered. This mine yields an unusual ore, having a greenish cast due to the presence of iron carbonate. On calcining, the ore becomes dark-

brown, the iron carbonate present being reduced to an oxide that is somewhat magnetic. A shaft-kiln is now calcining ore at the mine.

At Bissell the Rex Plaster Co. extracted several thousand tons from sedimentary deposits, a part of which was calcined in the company's rotary kiln at Los Angeles.

In Santa Clara county the Western Magnesite Development Co. has shipped both crude and calcined ore. The reduction plant is situated near the mine, which is on Red mountain, and motor-trucks are now employed in hauling the product to Livermore, a distance of 35 miles.

At Madrone, in Santa Clara county, H. Sherlock has shipped several hundred tons of impure magnesite. This was calcined at the plant of the Pure Carbonic Gas Co.

cesium salts with alkaline carbonates. The following are representative analyses:

SiO ₂	11.12	11.82
Al ₂ O ₃	0.98	0.94
CaO	5.36	5.20
MgO	36.72	36.40
Loss in ignition	14.15	43.45
	98.33	98.51

Considering that buyers of magnesite have established a maximum admissible limit of 5% SiO₂ and 3% CaO, this product would appear to be too low-grade.

CANADA. Magnesite was mined to some extent in Canada during the past year, in the township of Grenville, in the province of Quebec, and in Atlin township, Yukon Territory, and in the Lilloet district, 93 miles

north of Ashcroft. Canadian magnesite is usually high in lime, much of it containing 10 to 15% CaO. About 1000 tons was shipped into the United States during 1915, and it is believed that there is little likelihood of many future shipments owing to the impurity of the product.

MEXICO. The International Magnesite Co. commenced shipment of crude magnesite from its deposits on Santa Margarita island in the Gulf of California. The ore is brought by water to Chule Vista, California, near San Diego, where it is calcined in a rotary-kiln. The capacity of the plant is stated to be

ROTARY CALCINER FOR CALIFORNIA MAGNESITE CO. AT PORTERVILLE.

at West Berkeley, the carbonic gas recovered, and the residue sent to a paper-mill in Oregon for making pulp.

The White Rock mine, in Napa county, yielded several hundred tons of crude ore, which was shipped from Rutherford. Aside from the more important deposits mentioned, there are many smaller operations being conducted in various parts of the State.

Production of California by counties in short tons is as follows. (equivalent to crude) tons:

Sonoma	3,729
Santa Clara	7,270
Tulare	12,116
Napa	1,050
Other counties	6,890
Total	31,055

NEVADA. The discovery of a large deposit of magnesite in Clark county, a few miles from the town of St. Thomas, has been reported. This is said to be similar to that at Bissell, in California, which is of sedimentary origin. Magnesite is considered to have been precipitated by the contact of solutions containing soluble mag-

nesite with alkaline carbonates.

22 tons of calcined magnesite per day.

MARKET. The price of crude magnesite ranged from \$5.50 to \$12 per ton during 1915. Calcined magnesite sold at a wide margin, namely, \$20 to \$60, hence no fixed price can be said to represent the market. Domestic calcined magnesite in bulk sold for \$25 to \$30 per ton f.o.b. San Francisco, or other California points. When ground and packed in barrels, the price ranged from \$40 to \$60 per ton. Powdered Greek magnesite, when available, brought similar prices at San Francisco. Early in 1915 Austrian calcined magnesite was quoted at \$22 to \$25 per short ton, and Greek caustic magnesite, not ground, \$29 at ships' tackle in Atlantic ports.

MAGNESITE is used in the rubber industry. After calcining, the ore is ground to pass 200-mesh, after which it is put through water. The contained silica precipitates, the lime is dissolved and is taken up by water. The pure magnesite floats. The dried product is packed in paper-lined barrels and sells for 10 to 11c. per lb. to the rubber people.

The Re-Opening of Old Mines Along the Mother Lode, California—II

By T. A. Rickard

The Mother Lode is a gold-bearing fissure that traverses the western foot-hills of the Sierra Nevada in a line parallel with the main axis of that mountain range, which separates California from the State of Nevada. The productive portion of the Lode extends from Ophir in Mariposa county to Placerville in El Dorado county, a distance of 71 miles, but the full length of the Lode is about 125 miles, for it is stated to have been traced from Fresno county to mine workings north of the American river, into Placer county. The richest portion is within Amador county, where a nearly continuous series of productive mines extends along the strike of the Lode for 12 miles, the chief properties in order northward being the Argonaut, Kennedy, Oneida, South Eureka, Central Eureka, Eureka, Wildman-Mahoney, Lincoln, South Spring Hill, Keystone, Original Amador, Bunker Hill, Fremont, and Plymouth Con-

mines has been developed on an eastern spur from the main vein. Likewise across the Stanislaus river into Tuolumne county. But, as stated, the most intense ore deposition and the most successful mining are alike in Amador county, where are the deepest mines. Of these, the Kennedy has reached a depth of 3896 ft. vertically, while the Argonaut, at present the richest mine on the Lode, is down 4500 ft. on the incline, equivalent to 3900 ft. vertically. The recorded production of the Mother Lode region from 1880 to 1914 is \$153,000,000, of which \$69,000,000 is credited to Amador county. Allowing for the production before 1880 and since 1914, it is estimated that the Mother Lode has yielded a grand total of \$230,000,000 in gold, of which \$110,000,000 came from the mines in Amador county.

Statistics for last year, as compiled by Charles G. Yale, of the U. S. Geological Survey, are as follows:

County	Quantity, Tons	Bullion Produced		Gold and Silver Recovered on Plates, per Ton	Quantity, Tons	Concentrate Produced		Value in Gold and Silver per Ton,	Total Recovery, \$	Total Recovery per Ton, \$
		Gold, \$	Silver, Oz.			Gold, \$	Silver, Oz.			
Eldorado	21,428	63,796	418	2.99	403	35,425	540	88.58	99,707	2.65
Amador	819,550	2,519,284	27,144	3.09	17,155	1,364,575	12,521	79.91	3,993,969	4.76
Calaveras	383,808	502,125	4,742	1.31	10,316	388,843	4,824	37.93	895,818	2.33
Tuolumne	248,907	642,948	25,211	2.58	11,226	409,037	1,045	36.48	1,065,297	4.28
Mariposa	48,154	331,282	2,590	6.91	847	52,109	247	61.67	384,981	7.99
	1,521,817	4,059,335	60,405	2.52	39,947	2,249,989	19,177	56.57	6,349,772	4.17

solidated. (See accompanying map).

In this part of the lode-channel the gold-bearing quartz is distributed along one or more well defined fractures traversing black 'slate' (the Mariposa schist) where it is in contact with, or close to, 'greenstone' (diabase) dikes. These ore-bearing fractures have the same strike (north-west) as the country-rock, but they dip less steeply, although usually in the same direction (north-east). The point to be emphasized is the general coincidence of strike and the discordance of dip. In the principal mines the dip averages 65°. Lenticular masses of quartz more than 50 ft. thick are not uncommon, and they are as much as 1500 ft. long, but as a rule they are more persistent in dip than in strike, so that in their shape they resemble chimneys. Thus the Lode is not a single continuous vein but a system of fractures along which gold has been deposited, usually in association with quartz. Where this zone is constricted, the fissuring is almost continuous and the deposition of ore uncommonly persistent. Thus, in Calaveras county, where the Lode is wide and ill defined, the gold veins are scattered and unimportant, except at the southern end of the county, where, at Angels Camp, a group of productive

The counties are arranged in geographic sequence. Silver is estimated at 55.3 cents per ounce. The total of \$6,349,772 for 1915 compares with \$5,075,552 in 1914 and \$4,728,450 in 1913.

In Amador and Tuolumne counties at this time there is increased activity; the productive mines are doing well, and many idle mines are being resuscitated. This has prompted me to make a comparison between economic conditions prevailing, for instance, when the old Eureka mine was in its heyday of prosperity and today, when it is being re-opened. It is assumed by those engaged in unwatering the Eureka workings that the greater cheapness of material and the increased skill of the operators nowadays will enable them to exploit ore that could not be touched 30 years ago and to find ore that was missed by the miners of an earlier period. It will be interesting to enquire into the reasonableness of these expectations.

In 'American Mines and Mining,' a résumé of statistical and other data collected by Rossiter W. Raymond when Commissioner of Mining Statistics in 1871, I find a statement giving the principal items of cost at Sutter Creek on January 1, 1869. It is here appended, with the

TREES GROWING AROUND THE OLD EUREKA SHAFT JUST BEFORE IT WAS RE-OPENED.

corresponding prices prevailing on January 1, 1916.

COMPARISON OF COSTS

	1869	1916
Miners' wages	\$3 per shift	\$3
Surface labor	\$2.25 per shift	\$2.50
Lumber	\$28 per thousand	\$20
Fuel	\$5.50 per cord	\$5
Explosive	\$1.25 per lb.	12c.
Quicksilver65c. per lb.	70c.
Steel	18c. per lb.	6c.
Freight from San Francisco.....	\$20 per ton	\$4.25
Cost of mining	\$4.67 per ton	\$2.50
Cost of milling	\$2.15 per ton	32c.
Average yield of ore	\$20.34 per ton	\$5
Average recovery	74%	90%

The cost of labor constitutes 60% of the entire expenditure, therefore it is an important fact that wages remain practically the same. On April 1, 1916, however, the chief mining companies operating in Amador county, on the initiative of the Plymouth Consolidated, raised miners' wages to \$3.25 per shift. Surface labor is paid \$2.50 to \$2.75. In making a comparison with 1869, it must be noted that the shift then was 10 hours underground and 12 hours for surface labor; now the time is reduced to 8 and 9 hours, respectively. Whether an allowance should be made for the shorter time of work, I cannot say. My own opinion

is that 8 hours is enough for the man who works conscientiously, and that such a worker will accomplish very little more in 10 hours, but superintendents complain that they do not get 8 hours of real work and that the wasting of time reduces the shift to such an extent as to make the labor more expensive than formerly, when the shift was longer and the worker more willing. This is due partly to the spread of trade-unionism and partly to the change in the composition of the population of Amador county. In 1869 the men were mostly native-born Americans from the older communities east of the Missouri; today

they consist largely of Austrians, Serbians, Italians, and Spaniards.

As regards lumber and wood, there is no noteworthy change. Lumber is a little cheaper, owing to better railway transport, and wood-fuel has been replaced to a large degree by electricity. The materials used in mining—steel and explosive—are much cheaper. Just now dynamite costs 19c. per pound, owing to the War, but 12c. was the normal price two years ago. The consumption varies greatly as between neighboring mines, for instance, from two-tenths of a pound to one pound per ton of ore, so that this item is important.* The cost of steel as given covers the average for all kinds of steel material, such as drills, stamp-shoes, turn-sheets, cars,

*How the consumption of dynamite may vary is indicated by the fact that at the Bunker Hill & Sullivan mine, in Idaho, it is half a pound and at the Alaska Treadwell two pounds per ton of ore.

THE BUNKER HILL & SULLIVAN MINE, IDAHO.
SETTLING UP IN 1869

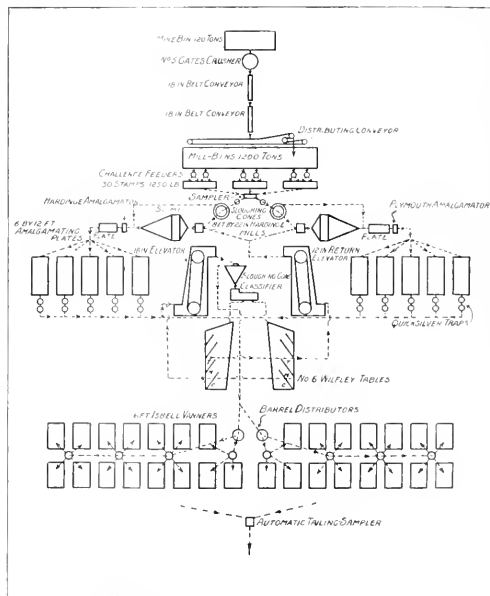

and rails, the last of these costing only $3\frac{1}{2}c.$ per pound, but the others raising the average to $6c.$ All shovels, hammers, and tools generally, are cheaper and better now than they were in 1869. The improvement in this department is emphatic. Quicksilver has been worth \$4 per pound recently, but $70c.$ is nearer the usual price and at that figure it is about the same as 50 years ago; but much less of it is used, and a smaller proportion is wasted, in modern milling.

Freight is important when assembling the parts of a new and large plant, but ordinarily it is not a heavy item in the economy of a gold mine, which requires a relatively small quantity of supplies. An American mining community consumes 12 lb. of supplies per ton of ore produced and a modern gold mine requires only 5 to 6 lb. per ton. Since 1869 the railway has been built from Sacramento to Ione and from Ione to Martel, which is only two miles from Sutter Creek, so that Latrobe is no longer the rail-head for this community, although it still serves Plymouth, which pays \$9 for freight from San Francisco. But, even if the freighting on machinery and supplies be a small item, it is certain that the facilities for the prompt delivery of necessary materials plays an important part in the comfortable operation of a mine.

The cost of mining given for 1869 is that at the Eureka; that of 1916 is obtained from the Plymouth Consolidated, which I quote as typifying the new order of things. The \$2.50 per ton includes 62 cents for development, $40c.$ for construction, and $21c.$ for depreciation; in short, it represents the real cost of mining and is not the illusory figure given so often, namely, the mere operating cost. The cost of milling at Plymouth can be divided into $34c.$ for the milling itself and $31c.$ for the additional cost of treatment and freight on concentrate, which goes to the Selby smelter on San Francisco bay. The total cost of mining and milling is \$3.30 per ton at Plymouth, and this is the figure that the management of the resuscitated Eureka can safely accept as a guide. As to the richness of ore, the old Eureka averaged \$27.38 in 1869 and out of this 74% was recovered; today the Plymouth ore averages \$5.50 and the extraction is 91%; the tailings therefore would contain \$7.11 and 49.5c, respectively in gold. Here we find convincing testimony of the increase of skill acquired by the modern metallurgist. At the Plymouth 30 stamps and 2 conical (Hardinge) tube-mills crush 360 tons per day, or 12 tons per stamp, while the old Eureka mill crushed 2 tons per stamp, in each case the fineness of grinding sufficing for the after-treatment.

The metallurgical treatment is quite different now from what it was in former days. In the old mills the stamps had wooden stems and were shod with iron, dropping in wooden mortar-boxes. Iron and steel slowly supplanted wood in every part. The gold used to be saved by amalgamation first in the mortar itself, on a plate inside, below the screen-outlet, and then on the 'aprons,' which were sloping tables covered with sheets of copper having a carefully prepared amalgamated surface. Screens of 20-mesh were used in the battery.

After the 'free gold,' meaning the gold less intimately mixed with the pyrite, had been extracted by amalgamation, the pulp passed down sluices, as in placer mining, in which the coarser particles of pyrite and other gold-bearing sulphides were concentrated. Blankets were also employed, after a fashion borrowed from Georgia, which derived it from Hungary. In 1871 the concentrate from the Eureka mill went to the chlorination works of Jones & Belding. In the report for 1876 mention is made of Hendy's apparatus, a sort of buddle, which represented one of the earliest attempts to introduce machinery for concentration. The belt machines came much later. For a long time chlorination held the field; even today the Kennedy concentrate is chlorinated; but the other mines now send this pyritic by-product to the Selby smelter, on San Francisco bay, at a cost for wagon-haul, railroad-freight, and treatment of \$12 per ton. The old chlorination mills used to charge \$20 per ton for treatment and pay 90% of the gold in the concentrate. To this, of course, the cost of wagon-haulage had to be added. Ob-

FLOW-SHEET OF THE PLYMOUTH MILL.

viously, the present custom of sending the concentrate to a smelter 152 miles distant is a confession of metallurgical failure. With a revival of technical enterprise, I expect to see the development of a method for treating concentrate locally.

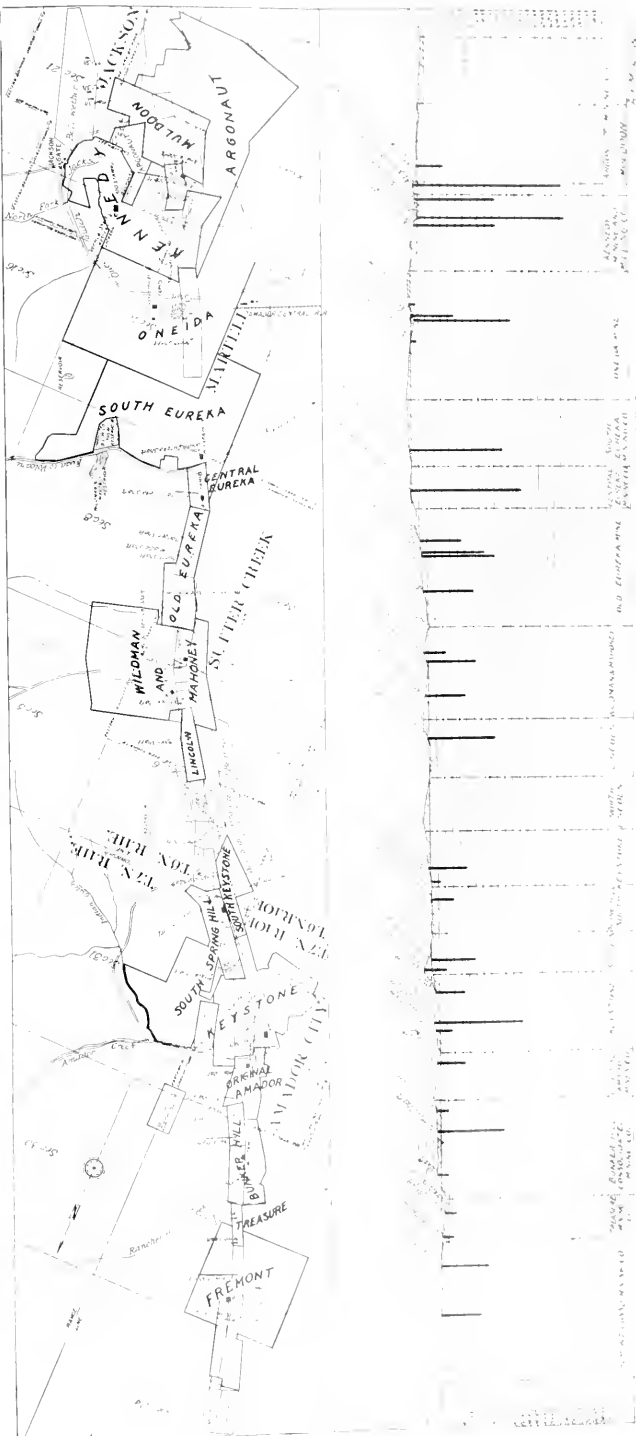

To furnish a contrast with the old metallurgy, I append the flow-sheet of the Plymouth mill, which is the latest, not the last, word in Mother Lode practice. This mill does credit to all concerned. It is clean, dry, and well lighted as compared with the sloppy dark sheds in which the old stamps used to splash. The 'aprons' are covered with silvered copper (1 oz. silver per square foot

of copper; and are uniformly coated with amalgam, in this respect also affording a favorable contrast with ancient days. The ore as it comes from the mine is fed to a Gates gyratory crusher and distributed by conveyors to the mill-bins, from which it is delivered automatically to the 30 stamps. Then the pulp is re-ground by two Hardinge pebble-mills. From these it goes to the amalgamators, which discharge to amalgamating tables. As first designed the pulp went thence to sloughing-off cones, the overflow from which was uniformly distributed to 24 vanners, while the spigot product from the cone went to a two-compartment Richards hindered-settling classifier, the spigot-product from which in turn was treated on two Wilfley tables while the overflow from the Richards classifier went to six vanners. This part of the flow-sheet has been changed because the feed to the six vanners varied so much as to prevent them from operating satisfactorily; the reason for the variation being the changes in the hardness and coarseness of the ore, and the occasional idleness of a 5-stamp battery. The spigot-discharge from the cone now feeds two Wilfley tables, all the tailing from which goes back to the Hardinge mills to be re-ground. A narrow streak of middling returns to the cone, this middling being a mixture of fine concentrate and fine sand, the result of incomplete classification.

However, the feature that distinguishes a modern plant, like this, from the old mills, is the sampling whereby the superintendent really knows what he is doing. An automatic sampler just below the battery gives the average content of the pulp before metallurgical extraction begins, and another automatic sampler outside the mill checks the loss in the tailing. While the old Eureka mill, for example, is credited with 74% recovery, it may be assumed confidently that this ratio flattered the skill of the superintendent, and that 65% is probably nearer the truth.

It remains to note the use of labor-saving devices. Since 1869 the machine-drill has gone far to replace human muscle. Machines have been introduced in many departments. The use of compressed air for sharpening drills and the heating of the bits with oil-fuel, instead of charcoal, may be mentioned; also the timber-framing machine.

Time is money; the mine-manager of today can expedite his work in many ways, and so accomplish a great deal more underground in proportion to the overhead expense. Rapidity of exploration has been gained by the introduction of the machine-drill. Where Hayward's men used to advance 2 to 3 ft. per day in a cross-cut, their successors now make 7 ft. with a machine. In a drift the speed is just double what it used to be. As the orebodies overlap, or follow *en echelon*, it is necessary to cross-cut freely. That the old-time miners, particularly the Cornishmen, would be slow to do. They preferred to follow a good gouge if no ore offered. As one honored veteran remarked to me: "When the Cornish miners got onto a streak of ore, they would stick to it till hell froze over, and never by any chance drive a cross-cut to find out if they had missed anything." Well, it is the second

rule of mining to follow the ore, the first rule being to find it, so I shall not blame them so severely, but when they "got off the pay" they should have shown no hesitation to cross-cut.

The bucket and hemp rope have been replaced by the skip and steel rope. A bucket used to hold from 500 to 2000 pounds; the skip carries from 2 to 5 tons. The handling of ore underground has been expedited. Huge timbers are not now necessary; for there is more back-filling of stoped ground. Ventilation and pumping have been improved; men work under better conditions underground, with better tools and explosives. On surface, electric lighting, the telephone, and the typewriter facilitate business.

All this tends to reduce the number of men 'on top.' In 1869 the Eureka employed 60 miners, 12 blacksmiths and engineers, 25 feeders, amalgamators, and teamsters, or 97 men altogether, of whom 37 were at surface, to produce 60 tons of ore, that is, $\frac{2}{3}$ ton per man. Nowadays the Plymouth reverses the ratio and produces 97 tons for 60 men, the actual average being 1.8 tons per man. This comparison goes to the root of the economics, for 60% of the cost of mining is recorded on the monthly pay-roll.

Thus the question of the cost of winning gold in this mining region is answered confidently in favor of modern practice. The cost per ton is about one-half what it was 50 years ago and the extraction of the gold is 15 to 20% cleaner. But in mining, especially gold mining, the chief problem is to find the ore. How have we progressed in that regard? I dare to put the advance at 50%. Those early operators—men like Hayward—were shrewd traders but they were not mining engineers. They lacked the scientific training of those who are now re-opening the old mines on the Lode. While geology is still a timid guide to the miner, the engineers in charge of development underground know more about the pitch of ore-shoots, post-mineral faulting, and the helpfulness of systematic sampling than the superintendents of 1869. Moreover, the maps and assay-plans are studied today with an insight undeniably greater and the use of diamond-drills, plus the rapidity of exploration obtainable by the use of machine-drills, has appreciably increased the chances for finding ore. Besides, the mine manager today has learned to watch details of expenditure and to systematize the whole of his highly specialized business in a manner foreign to the easy-going superintendent of a more romantic era.

The one thing that has not changed is Nature: the character of the Lode and the distribution of the ore; that still puzzles the most highly technical. Then, as now, some luck is needed—the luck of the miner. And he is entitled to it, for he takes his chances. Whether much ore has been left in old workings depends upon the definition of 'ore,' that is, how rich it must be to warrant the expense of re-opening. One old-timer told me, apropos of the opening of the Eureka: "If ever they get a mine, they'll have to find it." That is probably true. The gleanings will not suffice. But I believe they will find fresh orebodies. The experience of the Plymouth

is encouraging. That mine was closed down on January 1, 1888; twenty-five years later, in 1913, when the work of re-opening began, the water was running out at the top of the shaft. On August 1, 1914, the new mill began crushing. At the end of March 1916 a million dollars worth of gold had been won at a profit of \$300,000. When the new start was made, the main shaft was down 1660 ft., and the bottom level was at 1600 ft. vertical. A winze had been sunk 70 ft. below this level at a point 75 ft. north of the shaft; this winze averaged \$2 per ton all the way, except at the bottom, where a \$17 sample was obtained when the mine was pumped out. Apparently the bottom had not been sampled by those who worked the mine in 1887 or they had not cleaned up after the last round of holes. Anyway, they appear to have

missed the top of an ore shoot. The winze was sunk 130 ft. in ore averaging \$5.50 for a width of 8 ft. The length of this ore shoot, so far proved, is 300 ft. The shaft is now 2750 ft. deep on the dip or 2230 ft. vertically. When driving on the 1500 ft. level another ore body was cut; this has been traced up to within 875 ft. from the surface; it averages \$7.50 for a width of 12 ft. and for a length so far proved of 320 ft. This is a new asset unknown to the predecessors of Messrs. Albert Burch and W. J. Loring, who are now directing operations. Other chances of finding ore remain. This experience should encourage those who are reopening the Eureka. Horizontal exploration, by drifts and cross cuts, should be an important feature, for that is one of the advantages of a mine having a deep shaft.

Chilean Nitrate

The reported production of nitrate of soda in northern Chile during April was 5,337,592 Spanish quintals of 101.4 lb. each (541,231,929 lb.), while the amount exported to all countries was 4,913,379 quintals (498,275,630 lb.). The production for the same month in 1915 was 1,988,101 quintals and the exports were 2,964,136 quintals, and for 1914, 5,589,542 quintals produced and 4,444,371 quintals exported.

The price of nitrate increased somewhat during April, being quoted at \$1.80 per quintal at the end of the month, free alongside vessel, for the ordinary 95% nitrate and \$1.86 for the refined. The rise is due to a better demand from the United States.

There is not the same tendency to rush production that was evident during the latter part of 1915. The largest Chilean company has closed one of the *oficinas* operated by it, and a number of other *oficinas* will close as soon as they finish producing nitrate already contracted by them. Three *oficinas* owned by the *Compañia Salitrera Alemana*, and shipping through the port of Talta have been forced to shut-down, as no shipments could be made by them, due to lack of sacks. The embargo placed by British authorities tends to prevent German nitrate companies from securing the jute sacks used to ship nitrate. —*Commerce Report*.

Pyrite Production

The domestic production of pyrite in 1915 reached a new high level, due chiefly to the unprecedented demand for the mineral in making sulphuric acid. The output was 394,124 long tons, valued at \$1,671,933, an increase of 57,462 tons in quantity and of \$391,587 in value compared with 1911, according to W. C. Platen, of the U. S. Geological Survey. The consumption of ore, that is, the combined domestic production 394,124 tons, and imports 964,634 tons, was 1,358,758 tons, a decrease of 4521 tons compared with 1911. This decrease is due to a falling-off in imports. The general resumption of activity at acid plants especially created a great demand

for both foreign and domestic pyrite, and the imports, particularly of European pyrite, would have been larger if suitable vessels had been available for the carrying trade.

Costs at the McIntyre Mine, Porcupine

During the year ended March 31, 1916, this property yielded 105,758 tons of gold ore averaging \$7.71 per ton, at the following cost:

Mining:	Per ton	Milling:	Per ton
Labor	\$9.8132	Crushing, etc.	\$9.1029
Supplies	0.3063	Ball-mills	0.1502
Hoisting and tram-		Tub-mills, etc.	0.1721

Exploitation	0.0726		
Total mining	\$2.5116	Total Milling	\$9.618

The miner does not profit so much as the smelter by an increase in metal prices. The editor of *McIntyre and Chemical Engineer* remarks that at a part of the stopper of lead, silver, and copper concentrate has been received only 52% of the gross market value of the metal contained in the ore, leaving 48% for the smelter. This was when prices for the metals were high. A year previous when metals were at a lower price, the concentrate of about the same grade brought 66% of the gross market value to the miner and 34% to the smelter. One reason for this discrepancy may be that the smelter who prices are high is too busy to take in the concentrates but is desirous to encourage production when metal prices are low, so as to equalize sales and possibly the amount of ore shipped. A smelter should operate as regularly as possible.

Milling Practice at the Santa Gertrudis

By Hugh Rose

*The properties of the company lie within the Pachuca district, State of Hidalgo, Mexico, connected by three railway lines with Mexico City, 55 miles south-west, and by two lines with Vera Cruz, 250 miles south-east.

The ores were formerly divided by sorting into two classes, smelting and milling, the former averaging about 2 oz. gold and 335 oz. silver, the latter 0.12 oz. gold and 23 oz. silver. The smelting ores were sold to custom plants, principally the American Smelting & Refining Co. at Aguascalientes. The milling ores were treated by the patio process at the Guadalupe Hacienda, at Pachuca. This patio was probably the largest in existence at the time and continued in active operation up to March, 1910.

In January, 1910, the mines and patio were sold to English interests, represented by Camp Bird Limited. Two new companies were formed, the Compañía de Santa Gertrudis, to operate the mines, and the Compañía Beneficiadora de Pachuca, to build and operate a custom cyanide-milling plant. The capacity of the plant is 1100 tons per day.

DESIGN OF MILL. The ore-bins of 600 tons capacity feed two No. 6K gyratory crushers, discharging to a double screen 14 ft. long. The oversize from the 4-in. round-hole screen passes by conveyor to the tube-mill storage-bin, while the undersize joins the oversize of the 2-in. round-hole screen for crushing in two No. 4K gyratory crushers. The undersize from the 2-in. screen, together with the discharge from the secondary crushers, is delivered to a 22-in. troughed belt-conveyor, equipped with a Merriek weightometer.

The 22-in. conveyor discharges over the first of three Vezin samplers, a 5% cut being taken and stored in a sample bin of 15 tons capacity. The reject flows to a 30-in. shuttle-type flat-belt conveyor for distribution into bins of 2000 tons capacity. The first sample-cut is fed from the 15-ton bin through a set of 26 by 15-in. rolls reducing to $\frac{3}{4}$ in. and finer, and discharging to a second Vezin sampler cutting out 10%, which is delivered by a revolving Challenge feeder to the third Vezin, taking a 20% cut. A sample of 1 ton is thus obtained for each 1000 tons milled and is crushed to $\frac{1}{4}$ in. in a size F gyratory crusher, thereafter being cut down by Jones

rifles and reduced in the usual manner. Rejects from the second and third Vezin samplers and from the quartering-floor are returned to the battery-bins by an 8-in. elevator.

The ore passes from the battery-bins through Hoseur feeders to sixty 1550-lb. stamps arranged in units of 10 stamps each, 20 stamps being driven by a 65-hp. motor,

SECTIONAL VIEW OF STAMP-MILL.

belted to a jack shaft. The stamps make 102 drops of $7\frac{1}{2}$ in. per minute; 3-mesh and 4-mesh screens are used, the pulp from the batteries flowing through split distributing-launder to six primary duplex Dorr classifiers, the sand passing to six 5 by 16-ft. tube-mills, the discharges from which are delivered to the launder leading to the secondary classifiers by elevator or by reserve 10 by 54-in. Frenier pumps, one pump to each mill. The slime-overflow from the primary classifiers is laundered to eight secondary duplex Dorr classifiers, which feed the sand to four 5 by 20-ft. and two 5 by 22-ft. tube-mills, the discharges from which are returned by elevator or Frenier pumps to the classifiers.

The slime-overflow from the secondary classifiers

*Part of a paper to be read before the September meeting, in Arizona, of the American Institute of Mining Engineers.

passes to six primary Dorr thickening tanks, 35 ft. diam. by 15 ft. deep, wherein the pulp is thickened from 10:1 to 1.5:1.

The thickened pulp is delivered to a set of 11 primary Brown agitators 15 by 45 ft., operating in series; the discharge from the last tank in the series is by means of an air-lift, submerged in the tank itself, and delivering to a launder where a wash of four parts of mill solution is applied, the pulp flowing to four secondary Dorr thickening tanks, 35 by 15 ft., wherein it is again thickened to about 1.75:1 and delivered to a set of 11 secondary Brown agitators, 15 by 45 ft., also operating in series, the discharge from the last tank flowing to two 35 by 12-ft. storage-tanks equipped with mechanical agitators.

These storage-tanks feed, by gravity at 35-lb. pressure, four 90-frame Merrill filter-presses, size of leaf 4 ft. by 6 ft., width of frame 3 in. The tailing sluiced from these presses flows to four 35 by 15-ft. Dorr thickeners for recovery of water before passing to the tailing-storage dams. The pregnant solution is clarified by passing through four sand-filter tanks, 40 ft. diam. by 10 ft. deep.

Precipitation is effected by the Merrill zinc-dust process in two circuits, partial and barren, in order to economize the zinc-dust.

The precipitate is melted in a battery of eight oil-fired No. 400 crucible-furnaces arranged on the arc of a circle and served by a radial jib-crane, fitted with an air-cylinder for raising and lowering the pots.

All pumping of solution and water is concentrated in two pump-houses, one placed below the filter-plant and the other below the precipitation-plant. The pumps are of vertical triplex-plunger types, gear-driven by motors, and are installed so that one pump is in reserve for two circuits.

An electrically operated inclined tramway runs from the top to the bottom of the mill, delivering material to any floor.

Compactness of design was sacrificed in order to secure a gravity-flow. This was permissible owing to an unusually ample mill site of 17 $\frac{1}{2}$ slope, coupled with a mild climate requiring no housing of tanks. Supervision is made easy because the size of the plants warrants the division into two departments, mill and cyanide, and the tramway is used by the bosses in getting round. The mill is electrically driven throughout, 50-cycle alternating current being distributed at 440 volts.

THE CRUSHING-PLANT design exhibits no points of special interest. The elimination of elevator-returns and the favorable character of the ore make the operation unusually easy and simple. Consumption of steel liners, etc., is almost negligible. The 6K gyratory crushers, driven by 30-hp. motors, take only 15 hp. each. This is again due to the character of the ore and the large percentage of fine, which, if the ore had greater abrasive quality, it might pay to screen out beforehand.

An ample supply of mine-rock for use in the tube-mills, in place of pebbles, is obtained cheaply from the

revolving-screen oversize as described above. The Merrick weightometer is checked weekly against a weighed quantity of ore, the average error being well under 1%. Current weightings are corrected by the weekly factor thus obtained.

Particular attention is paid to securing an accurate sample of the ore delivered to the mill. Ordinarily two classes of ore are sampled separately each day. The rejects from these two are thoroughly mixed and quartered down, to make the mixture sample for the day. The calculated average assay of the two class-samples checks closely the assay-results of the mixture. The usual samples are taken for moisture, which averages about 5%.

STAMPING AND TUBE-MILLING. The design of the stamp battery follows standard lines except in a few minor details. The mortar-box foundation-bolts are crossed, as shown in the sketch, thereby permitting a broken bolt to be removed easily; none has broken thus far. A traveling crane, as well as a crawl, installed with the building, was found useful in erecting the battery and in making current repairs.

The stamp-duty averages 21.1 tons through 3-mesh and 4-mesh screens. Crushing is in mill-solution, 10 parts of solution to 1 of ore. Screen wear is of no importance. Steel wear per ton is: Shoes 0.16 lb., dies 0.08 lb., liners 0.60 lb. Life of shoes, 9 $\frac{1}{2}$ in. diam. by 14 in. long, averages 90 days; of dies 97 days; of liners 43 days. Shoes and dies are forged steel. Liners are cast-iron made locally. Manganese-steel liners have been tried, but the cost per ton crushed was considerably higher. The 65 hp. motors, each driving 20 stamps, are overloaded about 8%.

A trial was made of introducing the battery solution through nozzles in the back of the mortar box above the dies, but without success. Stationary screens placed between the feeder and the mortar-box to take out the fine were also tried and abandoned, the benefit being doubtful while requiring more supervision.

Average screen-analyses of feed and discharge of the stamp battery, equipped with 3-mesh, No. 32 wire screens, are:

Inches	Dis-		Inches	Dis-	
	Feed,	charge		Feed,	charge
	%	%		%	%
2	0.5	1.0	10	1.4	4.1
4	18.4	16.3	20	2.2	6.7
6	13.8	11.5	30	2.0	6.2
8	8.0	7.6	40	0.7	2.7
Mesh			50	0.8	3.2
10	18.7	16.3	60	0.4	1.7
20	11.5	10.2	80	0.1	2.7
40	1.8	7.6	100	6.0	21.2
60	8.5	11.8			
80	3.9	8.7		99.5	99.9

Distribution of the pulp from the battery to the primary classifiers by means of split launders could be improved by a mechanical distributor of one of the successful revolving types. The classifier platforms were built on an incline to save head room over the tube-mill

gears as well as to follow the slant of the classifiers. Returns to the classifiers from the tube-mills are by elevators with individual Frenier pumps as reserves. A better design, following later practice, would be to effect such returns by means of the classifiers themselves.

Tube-mill grinding is done in two stages, using 5-ft. mills throughout, the primary series being 16 ft. long and the secondary series 20 ft. and 22 ft. Comparison of this system with single-stage grinding has failed to show conclusive results in its favor, although a slight benefit is apparent. This benefit is, however, insufficient to warrant a repetition of this refinement of design unless in conjunction with water concentration, not required with this ore.

Danish flint pebbles were used for a considerable period, but their increasing cost led to the adoption of mine-rock. A supply is obtained mechanically in the crushing-plant as described and is sent separately over the regular conveyors to a compartment in the battery-bin from which it is transferred by chute to the primary tube-mill floor where it is distributed by ear. Part of the rock is introduced into the mill through the feeder. As the trunnion opening of the mills is not as large as it should be, rocks over 5 in. as well as occasional large boulders, 12 to 15 in., required in the primary mills for efficient grinding, are loaded into the mills through the manholes once per day; 130 lb. of rock is required for each ton of ore milled and is credited to the total tonnage treated.

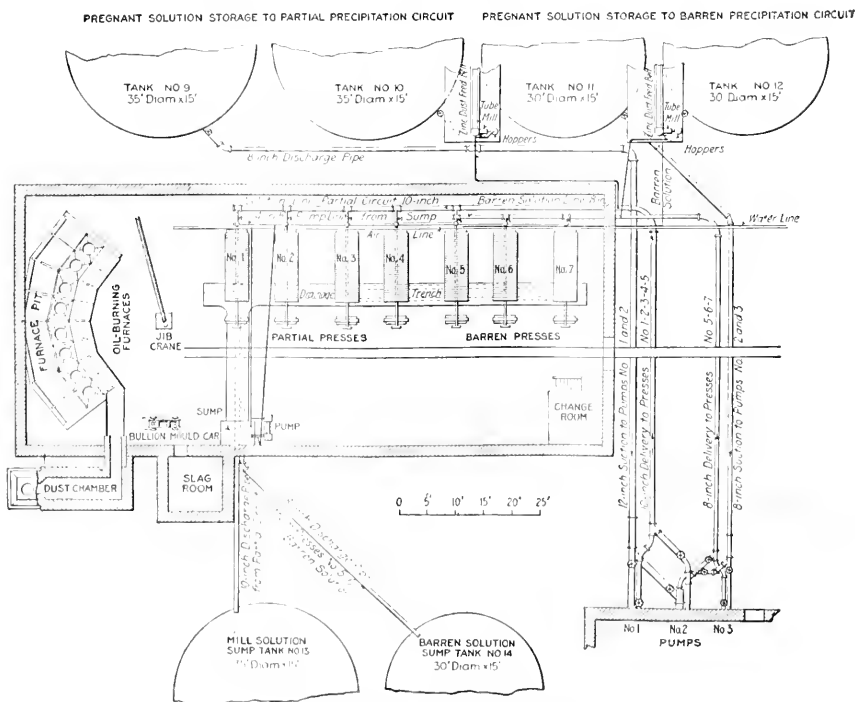

Tests are now in hand using cast-iron balls in place of rock. Results thus far obtained indicate a capacity increase of 33% with finer grinding. Power load shows an increase of 33%, from 65 to 90 hp. per mill. Forged-steel balls ordinarily used for such grinding were not obtainable but it is quite probable that chilled cast-iron or semi-steel balls and liners will prove more economical, taking into account the low cost of locally-made castings, 2.5c. per pound, as against high first-cost plus importation expenses of steel balls. Ball wear is 1.7 lb. per ton milled. Tube-mill liners are of modified El Oro type, of hard cast-iron, the average life being 6 months; cost 2.2c. per ton of ore milled.

The motor driving each mill through a flexible coupling and one reduction of spur gearing is of high-torque induction-type, 65-hp., 230 r.p.m. Allis-Chalmers make. Its ample design easily carries the over-load. But the power factor of this motor is low, 75%, and an improvement would be to use a higher-speed motor with a single reduction of herringbone gearing.

The economical grinding point is taken at 75% through 200-mesh. Screen-tests of feed and discharge of primary and secondary tube-mills, using mine-rock and at a plant-capacity of 1000 tons per day, are as follows:

Moisture, 35 to 40%. Operating without return, 175 tons of ore passes through tube-mill per 24 hours.

Moisture 35 to 40%. Operating with return, in closed circuit, 200 tons of ore passes through mill per 24 hours.

AGITATION. An extraction of 55.5% of the gold and 18.6% of the silver is made in the mill before the pulp reaches the Brown agitator system.

Cyanide of sodium, either 128 or 120% as obtainable, in lump or in brick form, is added at the first tank of the primary series, at the rate of 4 gr. sodium cyanide for each gram of silver in the ore delivered to the mill. The sodium cyanide consumed is 3.15 lb. per ton, including mechanical loss. The strength of solution at the beginning of agitation is 0.55% KCN; of the mill solution, 0.4%.

Protective alkalinity is maintained at about 0.75%; the lime, fed dry into the ore at the crushing-plant, is low-grade, averaging about 65% available, the consumption being 20 lb. per ton. Arrangements are in hand to improve the method of feeding by emulsifying the lime, adding it either to the primary tube-mills or to the Brown agitators.

Crude litharge, between 85 and 90% PbO, adopted in place of lead acetate as being both cheaper and more efficient, is ground in a small tube-mill, 24 in. diam. by 37 in. long, discharging into the first Brown agitator at the rate of 0.6 lb. per ton of ore. The best results are obtained with 72 hr. agitation although 60 hr. gives within 2% as high extraction. The air pressure is 27 lb., 75 cu. ft. per minute being required for each tank.

No difficulty has been experienced with the series operation of the Brown agitators. Connections between tanks are made by 10-in. horizontal pipes, placed 3 ft. from the top, the joint between two abutting pipes being made leak-proof by a wrapping of tarred canvas. This joint takes up the tank vibration and effects an easy connection. To avoid undue accumulation of slime on the inside of the tanks, they are emptied and sluiced once a month. This operation requires about 3 hours per tank, using a 3-in. Traylor slime-pump for the return.

Screen-tests of the inflow and outflow of the system

are practically identical, showing that there is no segregation or short-circuiting of sand or slime.

FILLING. This step in the process is difficult, owing to fine grinding of ore containing a considerable amount of colloidal matter. Also, the dissolved metal in the pulp to the filters is high, 3.5 oz. silver per ton of solution. After extended working scale tests of several types of vacuum and pressure filters, Merrill presses were adopted, using the centre system of filling. A press cycle occupies 75 min. made up of

	Min.
Charging	26
Barren solution wash	15
Water wash	13
Sluicing	23
	75

Bristol recording-pressure gauges are attached to the filling pipe of each press, the cycle curves from the chart giving an excellent check upon the care taken by the attendants in operating the presses. The sluice-valve bar and the filling valves are electrically connected so that both cannot be coincidentally opened without ringing an alarm-bell. The cakes average 1½ in. thick, thereby leaving ½ in. space in the centre of the 3-in. frame for entrance of washes. Dry pulp handled per cycle, 11.5 tons. Sluicing water is at 90 lb. pressure and five parts are required to clean out a press. The bulk of this water is recovered in dewatering tanks as explained heretofore.

No. 6 cotton duck, 72 in. wide, is used regularly, after extensive trial of several other weights. A set of cloths lasts about 2500 cycles. Acid washing to remove lime is done in the press every 10 days, using a 0.75% sulphuric acid solution.

Much care is taken with the nozzles of the sluice bar. The bar of each press is taken out and tested every 18 hr., any defective nozzles being replaced. Nozzles are ordinarily ½-in. cast-iron plugs, drilled ¼-in. hole; these last practically as long as special steel nozzles and are much cheaper.

The unwashed metals in the press discharge averages a trace of gold and 0.08 oz. silver, showing an efficiency of 97.7%.

PRECIPITATING. All solutions to be precipitated are first passed through ordinary sand filter tanks. The addition of about 40% by volume of sawdust to the sand considerably improves the clarifying efficiency of the filtering medium and at the same time reduces the frequency of slime-skimming and sand cleaning. The latter operation is effected by shoveling the sand from the tank to a launder leading to a small trommel where the sand is washed free of slime with small loss, and returned for reuse.

In this way, 4500 tons of solution is filtered daily at a cost of 0.28¢ per ton of solution. Possibly Merrill clarifying presses would be an improvement, although no comparative figures are available. At any rate the existing equipment does the work efficiently and cheaply.

The Merrill zinc dust process of precipitation has justified its adoption. Its efficiency, safety, cleanliness,

etc., compared to the zinc-shaving method are too widely known to need further elucidation here. The ease and rapidity with which a clean-up can be made gives it a further special advantage in a good-sized mill treating silver ores with the consequent considerable production of precipitate. Formerly the process enjoyed the advantage of a lower price for zinc-dust than for zinc-shaving; the difference now is practically negligible.

The solution from the sand-filters averages 0.015 oz. gold and 3 oz. silver. Two circuits are maintained, one precipitating to barren solution, sufficient for the filter-press washing, and the other circuit to an effluent containing from 0.9 to 1.2 oz. silver per ton. To accomplish this, a slight excess of zinc-dust is fed to the barren circuit in the proportion of 1.1 oz. zinc-dust to 1.0 oz. fine bullion; to the partial circuit 0.8 to 1.0. The average zinc consumption of the plant is an ounce of zinc for each ounce of fine bullion.

Clean-ups made at the middle and end of the month, and sometimes oftener, provide an accurate check on current work.

MELTING. The only drying of the precipitate is done by blowing air through the presses at 25-lb. pressure for an hour, reducing the contained moisture to about 30%. The precipitate is removed from the presses into rectangular steel cars, 5 ft. 10 in. by 6 ft. 4 in. by 1 ft. deep, in which it is weighed. Based upon the calculated dry weight of the precipitate, flux consisting of $1\frac{1}{2}\%$ each of borax and bottle-glass, is added on top without mixing, and the charge is then shoveled from the car into No. 400 crucibles. To permit the introduction of a high column of precipitate, a discarded pot with the bottom out is temporarily fitted into the crucible, being removed after the charge has melted. This procedure reduces dust losses and accelerates charging and melting.

The eight furnaces are oil-fired, built flush with the floor of the melting-room, on the arc of a circle with fire-pit at the rear. This arrangement has proved satisfactory and is to be recommended as convenient and labor-saving.

The crucible, upon being lifted from the furnace by tongs attached to $\frac{1}{2}$ -in. wire-cable raised or lowered by air-cylinder on the post of the jib-crane, is swung around to one side to the pouring-carriage containing the bullion-molds. The slag is first skimmed off, using sand. As the bars are poured, sticks of wood are laid on top and, igniting, prevent too rapid cooling of the centre of the bar with the consequent subsidence and holing.

The precipitate averages 85% fine bullion; the Doré bars weigh 1000 oz. and assay 5.0 gold and 940 silver fine. The No. 400 crucibles contain an average of seven bars per melt with a maximum of 10 bars. The average life of a crucible is 10 melts or 70 bars, which may be considered satisfactory.

With bullion of this fineness, no difficulty with matte formation is experienced. The bars are carefully cleaned and all chips and corners removed before sampling and weighing. Drill-samples are taken, one on the top of the bar, one-third the distance along the diagonal toward the

centre, and one on the bottom of the bar at one corner; each hole is drilled half-way through the bar.

Melting the precipitate in an electric furnace, built after the Alaska Treadwell and Lluvia de Oro design, is under trial. Alternating current at 120 volts is used, the input being about 600 amp. working at full heat. Trouble has been experienced with dusting and with burning a hole through the bottom of the furnace; a renewable iron plug may provide a convenient remedy for the latter. The dusting is probably due to the precipi-

ELECTRIC MELTING FURNACE.

tate being wet, the intense heat at the electrode setting up a central draft of steam and air. Either the precipitate should be dried or some dust-collecting apparatus attached to the furnace-top. The advantages of this system over the oil-fired crucible method of melting are rapidity of melting and discontinuance of the use of crucibles and oil, both of which require a long-distance haul.

Exports to the United States during 1915 totaled \$1,778,600,000, which is about the normal amount. Of this, more than one-third came from the British dominions; the next largest contributors were Cuba, Brazil, and Japan. Exports totaled \$3,547,500,000, which is a tremendous increase. Of this nearly one-half was to the British dominions. The next largest customers were France, which took 14%, Italy which took 7%, Russia, Holland, Cuba, and Scandinavia.

BROMINE production of the United States in 1915 was 855,857 lb., worth practically \$1 per lb., an increase of 278,866 lb. and \$653,213 over 1914.

Concentrates

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

RAILROADS of the United States consume 24% of the total coal production of the country.

GRASS VALLEY MINES, including Nevada City, yielded \$11.14 in gold and 7 cents in silver, or \$11.21 in both metals per ton in 1915.

ELECTRIC-POWER costs at the mines of the St. Joseph Lead Co. in south-west Missouri, range from 0.55 to 1.56 cents per kilowatt-hour. Gas-producers and gas-engines as well as steam-turbines and Corliss engines are used to generate the power. Coal is cheap in the region.

DWELLINGS owned by the Calumet & Hecla company and rented to employees number over 800, and 1000 other employees own houses on the company's land. The dwellings are piped with clean Lake Superior water, and the company removes all garbage. No stores are on the company's land, but many school-houses are.

AMONG Mother Lode mines the Eagle-Shawmut, in Tuolumne county, is remarkable because 85% of the yield of gold is won from the concentrate by means of chlorination. The concentrate has an average assay-value of \$39.21 per ton. Only 76 cents per ton, or 15% of the total yield, comes from the amalgamating plates.

PIPE-THREADS are cut differently on English pipe and fittings than on those of American manufacture. The number of threads per inch and the shape of the threads are different. Inconvenience frequently occurs at mines in foreign countries where part of the fittings are American and part are English. Care should be taken when ordering supplies in foreign countries to specify which thread is wanted.

RED WRAPPERS for dynamite sticks have been requested by the Alaska Treadwell Gold Mining Co. of the du Pont explosives company. Such wrappers make dynamite more conspicuous when scattered about or in missed holes. The idea was suggested at the Treadwell mine by a miner competing for the quarterly safety-first prize offered by the company, but is not new to the explosives manufacturers.

COST of mining and delivering ore to the mills in the lead district of south-east Missouri averages 85 cents per ton, of which 11c. is paid to miners extracting ore on contract by a per-ton basis. Compressed air for drilling costs 5c. per ton, and explosives 8c.; the cost of keeping roofs and backs safe is 3c. Trimming with mules or power-haulage underground costs 5c. exclusive of track work. Pumping costs 8c., the amount of water raised in the district averaging 12,000 gal. per minute against a head of 500 ft. The cost of diamond drilling and pro-

pecting may add 5 to 15c. to this amount. The output of ore per man for all underground labor is about 5.7 tons per day; that for all employees, including those engaged in mines, mills, and prospecting, is 3 tons per man-day.

HIGH-GRADE spelter is used for galvanizing telegraph and telephone wires that are required to stand sharp bending. If impure spelter is used, it cracks and peels off the wire. Cadmium is especially harmful for such use, as it makes spelter hard and brittle if present in amount of 1 or 2%. Some authorities, however, assert that the high temperature of brass pots causes so much of the cadmium impurity to volatilize that the remainder has little deleterious effect.

SHAFT-SINKING costs of 30 years ago are illustrated by the figure of \$61 per foot for the Tamarack No. 1 shaft at Calumet, Michigan. This vertical shaft was started in February, 1881, and struck the Calumet & Hecla conglomerate lode at 2100 ft. depth on June 20, 1885, 4½ years later. The lowest rate of sinking was 42 ft. per month, and the highest 70 ft. This was in tough solid rock, and uncertainty existed all the time as to whether or not the undertaking would be a success.

SHOVELING machines for loading broken rock into cars underground are being used in mines where the cost of shoveling is high on account of handling a large amount of low-grade ore, such as at the Lake Superior iron mines, and the underground porphyry-copper mines. Several types of mechanical loader are on the market. They are operated by electricity and are as compact as possible to enable working in a narrow drift. A patent has recently been granted to H. H. Talboys of Duluth for a particularly light-weight loader that will permit of easy transportation and have a low first-cost. This loader has no continuously moving parts, but follows the steam-shovel design of requiring motion only when the excavating bucket is doing work. This bucket is actuated by an arm much as on a steam-shovel.

CINNABAR float found on a hillside should be located as a placer, not a lode, claim. The rule is that "if a discovered deposit satisfies the law as to its mineral character, and it is not found in veins of quartz or other rock in place it may be appropriated under laws applicable to placers." ("Lindley on Mines," Sec. 119.) The element of commercial value, its susceptibility of being extracted and marketed at a profit, are the controlling factors in determining the question. It has been held by the Supreme Court of Nevada in *Rogers v. Cooney*, 7 Nevada, 213, that abandoned re-mining that has been suffered to flow and accumulate in vacant and unappropriated public land is subject to placer location. It would seem, therefore, that if in original deposit of this kind can be located as to placers so much the more would the mineral-bearing rock that is reached in its present position be subject to placer location. The being merely the result of a course be not a basis on which to predicate a lode location.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

ANCHORAGE

In the Broad Pass district there are about 30 prospectors busy, with a number going in. The Government camp at Talkeetna has facilitated transportation. Recently E. Miller and others opened rich silver-lead and copper-gold ore on Ohio creek. This area is expected to develop into an important lode district.

On July 22 the Government held a sale of town lots at An-

chorage. A total of 131 were sold, realizing \$28,740, at prices ranging from \$75 to \$700 each.

In Bulletin 642-F of the U. S. Geological Survey Stephen R. Capps discusses gold mining in the Willow Creek district. Work continued during 1915 on about the same scale as in 1914. The output is derived mainly from the three mines that have been operating for several years, namely, the Alaska Free, Gold Bullion, and Independence. These are equipped with mills, the first two with cyanide-plants, and employ a total of about 120 men during the season. Other mines of the district are the Mabel, Rosenthal, Shough, Jap, Mammoth, and McCoy. Some hydraulic mining was done. The total output in 1915 was \$843,901 gold and \$1828 silver.

CORDOVA

Shipments of copper in ore from Alaskan mines during the first five months of 1916 are as follows, in pounds:

	1916	1915	1914
January	9,365,733	2,149,476	2,784,802
February	10,913,458	3,678,880	1,859,360
March	10,992,707	2,149,272	2,133,980
April	12,992,523	2,845,980	1,319,110
May	12,405,421	3,525,600	603,492

At present the Kennecott company contributes 10,000,000 lb. monthly to the total.

JUNEAU

During July the Alaska Gastineau mill treated 140,043 tons of ore, yielding \$1.24 per ton.

SEWARD

A meeting was held at Seward on August 1 to consider the question of erecting a smelter there. The copper mines tributary to Prince William sound are estimated to contain 1,000,000 tons of ore. The smelter at Tacoma is unable to handle all that is offered.

ARIZONA

COCHISE COUNTY

BISBEE. During the second quarter of 1916 the Shattuck-Arizona Copper Co. produced 4,194,873 lb. of copper, 192,459 lb. of lead, 1047 oz. of gold, and 70,350 oz. of silver. The cost was 10.44c. per lb. of copper. Profits were \$689,615, against \$781,380 on the first quarter.

GILA COUNTY

MIAMI. Fifteen miles south-east of Miami, near the properties of the Pandora Copper Co., Arizona Zinc & Lead, Cole Development Co., Independence, Pinal Development Co., Troy & Arizona, Gila Development Co., and Ray Eastern & Whitcher is that of the Greater Miami Copper Co. A fair amount of development has been done, and veins containing gold, silver, copper, and lead exposed. More men are to be employed in charge of N. W. Tanner. Road construction is under way.

On one day last week the Inspiration mill treated 16,900 tons of ore. Steel workers are busy on the extensions. Carpenters are erecting trestles for tailing launders in Warrior canyon.

GLOBE. The North Dominion Copper Mining & Development corporation is being organized by A. Billard and S. Sutherland of Globe to develop the Mercer property at Radium, near Globe. Past work indicates promising results.

OFFICIAL MAP OF PART OF THE RAILROAD UNDER CONSTRUCTION
IN ALASKA.

MOHAVE COUNTY

CHLORIDE. At a depth of 120 ft. in the Schenectady mine rich zinc-silver ore has been opened. It is similar to that at 1400 ft. in the Tennessee.

OATMAN. All kinds of rumors are current concerning the Big Jim mine. Engineers representing various syndicates have been examining the property. A consolidation with adjoining mines is mentioned. The daily output is 30 tons. At 400 ft. the vein assays \$46.36 per ton for the 184 ft. of openings. The 500-ft. level has been opened for 195 ft. Close to the Big Jim shaft the Tom Reed company is sinking a shaft.

The Sunnyside mine, adjoining the Tom Reed, has been financed by Los Angeles people, including Seeley Mudd and John Wuseman, involving \$85,000.

PIMA COUNTY

AJO. The New Cornelia Copper Co. has 750 men employed. Excavation, foundations, and other work at the mill-site is well advanced. Overburden is being removed from the ore-body. Streets, water and sewer systems, and stores at Ajo are making good progress. The town plaza is finished.

YAVAPAI COUNTY

JEROME. It has been hinted by James S. Douglas, president of the United Verde Extension company, that a smelter and other treatment plant are eventually probable. High-grade ore continues to be shipped to smelters. This company is also developing the Jerome-Verde mine from the Extension's 1400-ft. level.

YUMA COUNTY

(Special Correspondence.)—Work on the plants of the Yuma Consolidated and the Plomosa company's is progressing as fast as the great heat and transport delays allow. The Plomosa expects to begin operations not later than September. The Yuma company will have a 2000-yd. and the Plomosa a 1000-yd. plant. At present great interest is being centred on a deep hole on the Yuma ground, the first of its kind in that district, intended to be an experiment and a demonstration of what had been considered heretofore by old-timers to deep to be of much value. This hole, which is 140 ft. deep, has been a revelation. At the surface the gold was rather fine, at various depths rich seams were cut averaging 12 to 20 in. in width, and worth up to \$12 per yard. A hard strata of cement was then penetrated, which also carried finer gold and then the layer of bedrock gravel was met with, which was found to be thick. Of this seam, 15 ft. above bedrock averaged better than \$6.65 per yard, while the whole bed of gravel and cement to the surface yielded over \$2, thus proving that for work in a large way the deeper ground of the district may be found to be even better than the partly worked and shallower ground; the later areas still have ground that will return \$12 per yard.

Regardless of the hot weather many engineers are visiting the district to see the test-plant operating, erected at a cost of \$65,000. Runs were made, the pulverizer and Stedins dry concentrator doing good work, practically 97% of the gold being recovered. A large influx of mining people is expected on the approach of cooler weather, and as a consequence every foot of ground has been covered for 15 miles.

Quartzite, July 31.

CALIFORNIA

BLIND COUNTY

(Special Correspondence.) The Mineral Slide drift mine near Magalia, owned by L. Cohn, J. Gooday, and S. Moody has been bonded by John Cowan and associates of Salt Lake City. C. E. Hand of Los Angeles is in charge. Work has been proceeding steadily during the past month. Twelve men are at work and the old flume and ditch are being repaired. When this work is completed a 1500-ft. bedrock adit will be driven on a sluice-grade to cut the gravel at depth. Mucking ma-

chines will be used and all labor-saving appliances possible. The price fixed on the property is unknown, but is thought to be about \$100,000. This property has produced approximately \$1,000,000 in gold since first opened and is still considered good. Apparatus to save the fine gold and black sand will mean success for this property, as it would with many other drift mines in this State. The present company has the money. Visitors at the Exposition will remember the gold exhibit in the California building. Nearly all the gold in the Butte County exhibit was from the Mineral Slide mine, one nugget being worth \$193. The gold in this property is coarse, and much platinum is found in the black sand.

The Lucky John mine, adjoining the Mineral Slide on the east, owned by J. D. Hubbard and others of San Francisco, has completed the work on a 1000-ft. adit and 96-ft. raise, and will soon be washing gravel. This property is up stream from the Mineral Slide and holds excellent promise to become a steady producer.

Magalia, July 30.

CALAVERAS COUNTY

(Special Correspondence.)—The manager of the Calaveras Copper Co., S. M. Levy, reports that the company is doubling the flotation plant, bringing the capacity to 500 or 600 tons daily. The new installations will include one 8-ft. Hardinge conical ball-mill, a 20-ft. Dorr thickener, 11 pneumatic flotation-cells, and a 11 ft. 6 in. Oliver filter. The flotation process has proved a success here. Concentrate from the old method was never higher than 6 to 8% copper, while the flotation makes a product of 15%, which could be raised to 18%, but would probably result in a greater tailing loss. The new 3-compartment shaft is completed to the sixth level. A new machine-shop has been erected at this shaft, where all repairs for mine and mill may be made. A new rock-crushing plant has been erected near the mill, to be in commission within two weeks. This plant will be capable of crushing 1500 tons of 14-in. and smaller size, in 24 hours. Power is supplied by the Sierra & San Francisco Power Co. Coffey & Trask, lessees in the upper workings of the mine, are producing 10 to 15 tons of shipping ore per day.

A. Wetzel is mining and shipping chrome from W. F. Hendsch and Campbell & Perry's properties near Copperopolis. About 100 tons has been shipped. Rant & Deane of Felix have shipped 60 tons. While there seems to be an abundance of chrome in this area, freight rates, owing to bad roads and distances, make the margin of profit an uncertainty. Mr. Wetzel will soon open a body of manganese ore on the Stack-pole ranch near Milton, and has taken a bond on another manganese property near Bear mountain.

The American Asbestos & Manufacturing Co. of San Francisco is developing a large deposit of asbestos near here. A plant for separating the fibre from the rock is being installed at present. Excavating for the mill is being done with 12 men. A large body of asbestos which can be worked practically as a quarry in benches, is under the control of this company, and as soon as roads and other freight problems are solved there will be a great quantity extracted. J. A. Voorhes is manager of the company.

Copperopolis, August 1.

INYO COUNTY

BISHOP. The new 30-ton mill of the Tungsten Mines Co. is practically complete. Development continues satisfactory.

NEVADA COUNTY

NEVADA CITY. Mining men of the place and Grass Valley have bonded the old Bell mine near Columbia Hill. R. Temeroux, of the Charpen mine at Grass Valley, is in charge.

GRASS VALLEY. At the Allison Ranch mine building construction is well under way, nearly ready to receive machinery. Foundations for the hoist frame are being poured.

and grading has been started for the mill. A water ejector is to be used in unwatering the first part of the shaft. A larger drum has been fitted to the main-shaft hoist of the Brunswick mine.

PLUMAS COUNTY

COLFAX. The new mill at the Walker copper mine is practically complete. Assays of the vein in the face of the 1000-ft. adit average 7.14% copper, 3.6 oz. silver, and \$1.20 gold per ton.

SIERRA COUNTY

ALLEGHANY. In the U. S. District Court at San Francisco the Twenty-One Mining Co. is being sued by the Sixteen-to-One Mining Co. for \$100,000 and an injunction, alleging that the Twenty-One is trespassing in the Sixteen-to-One's ground.

TULARE COUNTY

PORTERVILLE. On pages 225 and 234 of this issue will be

OUTCROP AND OPEN-CUT ON MAGNESITE VEIN OF LINDSAY MINING CO., PORTERVILLE, CALIFORNIA.

found some interesting notes on the magnesite situation, directly affecting the Porterville district.

COLORADO

LAKE COUNTY (LEADVILLE)

It has been found that a creek flowing down Evans gulch was pouring into workings of the Harvard shaft of the U. S. S. R. & E. Co., preventing the pumps from draining the ground. At first this was thought to be a natural flow in the mine. This surface water is to be diverted.

The Tarsus shaft on Yankee hill has been repaired to 600-ft. depth. On the bottom level a large vein assaying 89 to 309 oz. of silver and 11 1/2 copper has been found, and promises to be persistent.

The Connors lease at the Ibez last week shipped one ton of ore, yielding gold metallies worth \$2470 on screens, after which is assayed 105 oz. per ton.

OURAY COUNTY

OURAY. The H. A. C. Tunnel & Mining Co. has been incorporated with a capital of 1,000,000 shares at \$1 each, to develop 30 gold-silver claims in the Uncompahgre district, 2 1/2 miles from Ouray. An adit has been driven 800 ft. to cross-cut the property, and in 400 ft. the first large vein is expected, which has a good surface outcrop. Some interesting work is contemplated.

TRILER COUNTY (CRIPPLE CREEK)

The Roosevelt drainage-tunnel is now in 850 ft. east of the Elktion shaft, in breccia formation. A little over 12 ft. is being advanced daily. The flow of water is 11,200 gal. per minute, a decrease of 2500 gal. since July 1.

The July gold yield was as follows:

Plant	Tons	Average Value	Gross Value
Golden Cycle	34,000	\$18.00	\$612,000
Portland	12,000	20.00	240,000
Portland	18,000	2.79	50,220
Portland	14,550	1.92	17,936
Reid-Gold Sovereign	1,350	2.50	3,275
Worcester-Rubie	250	2.90	725
Smelters	4,750	55.00	261,250
Totals	84,900	\$13.96	\$1,185,406

Dividends paid totaled \$210,000, \$90,000 by the Victor, \$90,000 by the Portland, and \$30,000 by the Golden Cycle.

KANSAS

CHEROKEE COUNTY

COLUMBUS. Several farms 5 miles south of this place have been leased to Picher and Commerce, Oklahoma, men, who are to prospect the 1200 acres by drilling. They consider that an extension of the Miami, Oklahoma, field is possible. This marks the third prospecting campaign started recently north of the Oklahoma border. A total of 6000 acres is to be tested by all concerns.

MICHIGAN

THE COPPER COUNTRY

Houghton. It is probable that the Mayflower company will sink a shaft in the near future, although officials do not affirm the rumor. Farmers working on the surface have been told not to plant their next crops. The geology of the property has been studied recently.

An assessment has been made by the Keweenaw. Crushing of ore may start in September.

In connection with the Tamarack mine and G. M. Hyams, several shareholders are to bring suits against him for his interference in the sale of the property to the Calumet & Hecla, whereby they may lose a good deal of money.

MISSOURI

JOPLIN DISTRICT

JOPLIN. On account of the great increase in mining activity in the district the use of natural gas has advanced 25% during the past two years. The Kansas Natural Gas Co. reports that in May of the past three years the consumption was 41,000,000, 55,000,000, and 75,000,000 cu. ft., respectively.

The past week was uneventful in the ore market. The district's output was 4550 tons of blende, 66 tons of calamine, and 954 tons of lead, averaging \$66, \$44, and \$72 per ton, respectively. The total value was \$374,172.

Owing to prices of zinc blende only averaging \$66.30 per ton during July, miners will receive 25c. per day less.

The Ramage No. 6 mill is now ready to treat 1000 tons of ore daily, one of the largest in the district. Wilfley tables, Dorr thickeners, sand rolls, jig, screens, etc., costing \$18,000 were recently installed.

GALENA. The new smelter of the Eagle-Picher Lead Co. commenced operating on July 27. It is thoroughly modern, costing \$100,000. Considerable attention has been devoted to a change-house for employees. John McClaren is manager. Coke from Collinsville, Illinois, is being tried; if successful, it means a large saving over coal.

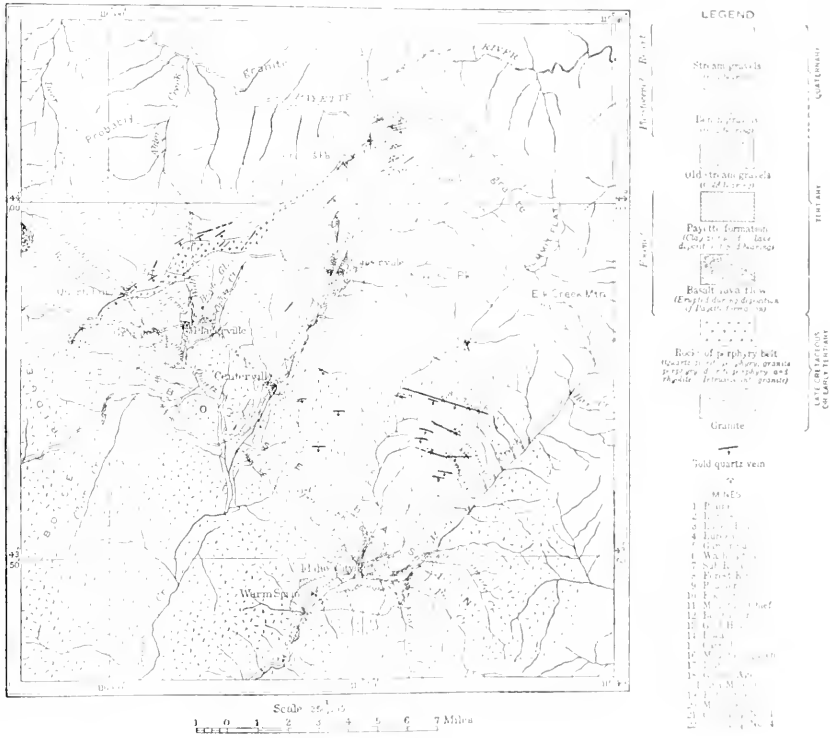

IDAHO

BOISE COUNTY

QUARTZBURG. Lode mining in the Quartzburg and Grimes Pass porphyry belt on Boise Basin is described by E. L. Jones, Jr., in Bulletin 640-E of the U. S. Geological Survey. Idaho City, Centerville, Placerville, Quartzburg, and Pioneerville are

the principal centres of the region. The Basin has a population of 700 people, compared with thousands in the early days. Roads connect the towns. Quartz mining commenced soon after the placers were found. In 1867 there were 10 mills in operation, treating free-milling ores. The refractory ore, now attracting attention, a process having been devised. Gold output of the district from 1863 to 1914 is estimated at \$53,096, 995. Large dredges are now working creek-bed gravels, the yield in 1912, 1913, and 1914 being over \$500,000 per year. Natural conditions are favorable to mining, including timber, sites, water, and power. The future of the area will depend largely on the adoption of suitable treatment for the ores, which are becoming increasingly base. Veins occur in zones of sheeted granite, the Quartzburg and Grimes, and Gambrius belts being the most persistent. Oxidation only ex-

reorganizations at Spokane. A new mill soon to be completed. The Consolidated Interstate Coal Co. reports as follows for the second quarter of 1916: One milled (25.08), zinc, tons 18,000 One and concentrate shipped 18,000 and 48,000 zinc, tons 18,000 Zinc in products, pounds 26,850 Cost of mining, per ton \$1.97 Cost of milling, per ton \$1.49 Profit \$71,675 Compared with the first quarter net earnings were \$60,000 less, yet they were more than sufficient to pay the quarterly dividend of \$1.50 per share. MURRAY. The new mill of the Empire Copper Co. is about

GEOLOGIC MAP OF THE BOISE BASIN, IDAHO.

tends a short depth below the surface. Pyrite and sphalerite are the most widely distributed minerals. The report devotes a good deal of space to notes on the several mines.

IDAHO COUNTY

ELK CITY. H. L. Herkath and others of Spokane have secured a bond for \$15,000 on the Gold Drop claim, six miles away. The mine has been fairly well developed, showing 270 ft. of \$9 gold ore. A 15-ton mill is to be erected.

SHOOSHONE COUNTY (COEUR D'ALENE)

KELLOGG. Lead miners of the Coeur d'Alene received the bonus of \$1 per day for July.

BURKE. The Hecla Mining Co. pays 15¢ per share, or \$10,000, on August 29. This makes \$950,000 for 1916.

The Marsh and Ambergis companies recently completed

the north fork of the Coeur d'Alene river is treated 2,000 tons daily and will soon be into the larger capacity. Concentrate contains 22.5% copper.

WALLACE. In its two years the Hecla mine has now treated 150,000 tons of ore daily. A good deal of ore being shipped direct to smelters. The mine is now developing a new vein of high-grade ore.

HOVAT, IDAHO

IDAHO COUNTY

At the head of the Snake River, at the mouth of the Boise River, the Coeur d'Alene Co. is developing a new vein of high-grade ore. The mine is now developing a new vein of high-grade ore. The mine is now developing a new vein of high-grade ore.

GALLATIN COUNTY

THREE FORKS. Within three months the Three Forks Copper Mining Co., 7 miles north, will be shipping ore. Reserves are considerable down to a depth of 425 feet.

LEWIS AND CLARK COUNTY

HELENA. Claims in the Scratch Gravel and Grass Valley districts are to be developed by the Cruse Consolidated Mining Co., recently formed. R. A. Weisner of Helena is secretary.

SILVERBOW COUNTY (BUTTE)

At 1000 ft. depth in the Butte-Detroit the company is to put in a cross-cut 800 ft. to cut the vein opened on the 500-ft. level. The Ophir mill is to be started early in September.

During the second quarter of 1916 the North Butte Mining Co. treated 146,190 tons of ore, yielding 6,974,742 lb. of copper, 264,400 oz. of silver, and 442 oz. of gold, compared with 131,071 tons, 5,749,193 lb., 244,976 oz., and 365 oz., respectively, in the first quarter. A good vein was cut in July, 15 ft. below the 3500-ft. level in the Granite Mountain shaft, 500 ft. below the present deepest working level.

Owing to the lower price of copper in July, wages at Butte have been reduced from \$4.50 to \$4.25 per day.

The 2000-ton zinc-ore concentrating plant of the Anaconda was expected to start work on August 5, also the electrolytic zinc refinery at Great Falls on the 10th.

According to the manager, W. L. Creden, the Davis-Daly gives most hopeful indications of ultimately developing into a sizable and profitable mine. Prospects lie on the Hesperus orebody, which has been definitely found on the 2500-ft. level. At this point the orebody has been opened for 450 ft., with an average width of 12 ft., the ore assaying between 5 and 7% copper. The breast of the drift on this level is still in ore. Development of this orebody contemplates openings above and below 2500 ft. and to this end a drift is also being put in on the 2400-ft. level, where it is expected that the vein will be encountered in about two months. The new hoist should be in commission about October 1, at which time production should be doubled from the present total of about 135 tons per day. There is, however, no attempt being made at present to extract ore except that which is met with in development. The aim is to keep income and expenditure balanced pending the time when the Hesperus orebody has been developed to a point where a substantial tonnage of ore can be economically mined. With copper at its present prices it is calculated that the Hesperus will easily pay for its own development. Aside from the favorable showing in the Hesperus, Davis-Daly has an asset of potential value in its Hibernia claim, next to the Nettie which the Anaconda company is developing as a zinc mine. No work is being done on the Hibernia at present.

At 500 ft. in the Butte & Great Falls mine a heavy flow of water has necessitated installing a 500-gal. pump and 100-hp. motor. The Dewey vein is close at hand.

NEVADA

ELKO COUNTY

(Special Correspondence.)—The following notes cover the Gold Circle district:

The Gold Circle Queen is being opened by lessees. So far they have milled 200 tons, mostly through a two-stamp mill. Some was crushed at the Elko Prince, but the haul to the latter mill is expensive and the service decidedly unsatisfactory. The lessees announce that they have secured a lease on the Rex five-stamp mill, and will haul the best of their ore there. The gold is generally very fine, but is readily amalgamable. The Rex is equipped with a modern cyanide plant, the stamps being followed by a tube-mill, but it is not known whether the lessees will attempt to make use of it. The ore-shoot developed in the Queen is a little over 80 ft. long, and varies from 1 to 8 ft. in width. Four feet of this, in the north

drift, assays \$50. The whole shoot, as far as developed, would be first-class mill ore if a plant were on the ground.

Early in July the Elko Prince company sent out nearly 1300 lb. of bullion, the June clean-up. No information as to its value is available, but it is estimated locally at \$70,000. Recently the Prince completed the cross-cut to a parallel vein on the June Bell claim. It has proved to be of good milling grade, resulting in the addition of a substantial supply for the mill, and a rise in Elko Prince shares, which are now around 40 cents.

On the Gold Circle group, Randall brothers have opened a shoot of high-grade ore for 20 ft. The vein is from 15 to 18 in. wide, with an additional 24 in. worth \$12 to \$15. Silver has predominated so far, but the gold-content is increasing with depth. This strike brings a new section of the district into prominence. Bamberger's \$10,000 pocket on the Midas ground is not far from the Randall find, but the Bamberger strike had become ancient history, and many of the newcomers were inclined to become skeptical as to the existence of rich ore. So this latest find comes at an opportune time. Lessees would be all over this ground if there were adequate milling facilities close at hand. The Prince mill is in an out of the way place and has a monopoly of the custom business at present. There should be more here.

Noble and Stone have completed their road to the Lucky Boy shaft on the Grizzly group, and will begin hauling ore to either the Prince or Rex mill.—Lessees on the Missing Link claim are mining some shipping ore, and have a fair tonnage of mill ore on the dump.

Midas, July 31.

ELKO COUNTY

(Special Correspondence.)—An experimental plant, costing about \$50,000, is being erected one mile south of Elko for the extraction of gasoline from the immense beds of shale in this neighborhood. Tests indicate each ton of shale will yield approximately 200 lb. of paraffin. The project is financed by R. M. Catlin of New York.

The Tobar zinc mines at Tobar, a new town 80 miles from Elko, are being operated by the Nevada Zinc Co. It is stated that enough ore, much of it high grade, is opened to warrant building a smelter, and officials of the company recently inspected the new plant of the Anaconda company in Montana.

Salt Lake City people are vigorously developing the Clipper mine south of Tecoma. The ore contains a good deal of silver and lead, with traces of gold. In sinking the main shaft, now 90 ft deep, there is still ore in the bottom. From the 80-ft. point driving is under way and small shipments of ore are going to Utah smelters. The group comprises six claims, situated between the Tecoma and Copper Mountain mines, both noted early-day producers.

Elko, August 6.

ESMERALDA COUNTY

GOLDFIELD. The estimated production of the Goldfield Consolidated during July is \$183,600 from 26,700 tons of ore. The profit is \$30,000. During June net costs were \$5.11 per ton. The second section of the mill should be converted to flotation by August 15.

CUPRITE. Thirteen miles south of Goldfield the Los Angeles Sulphur Co. owns large deposits of sulphur, recent shipments being paid for on a basis of 75% pure sulphur. A camp is being erected for employees, and a contract has been arranged for 250 tons of ore per month. A. W. L. Dunn, with headquarters at Goldfield, is in charge. Sulphur is worth \$30 to \$32 per ton in San Francisco.

HUMBOLDT COUNTY

(Special Correspondence.)—News has been brought to Winnemucca of an important copper discovery in the Jackson mountains, about 32 miles from Jungo, a station on the Western Pacific railway. According to the reports of miners there

are two distinct copper-bearing lodes in a monzonite formation, traceable for 12,000 ft. with a width of 1800 ft. One vein contains carbonate, the other consists of sulphides. Assays range from 1 to 15% copper. Arrangements have been made to ship the best ore to Jungo by mule-teams, and negotiations are proceeding for the building of a 50-ton plant.

The new 20-stamp mill at the Kramer Hill gold mine, two miles from Golconda, has been tested and is ready to start crushing. A large reserve of good-grade ore is exposed.

Work has been resumed at the Adelaide copper mine in the Gold Run district, 12 miles south of Golconda. Several buildings are under construction and mine workings are being placed in shape for a large output. The property was recently acquired by John G. Kirchen and associates of Tonopah. Charles Kirchen is superintendent.

Walker brothers of Salt Lake City have taken an option on the Granite Creek tungsten mine, 20 miles north-west of Golconda, and started work. The orebody in places ranges from 20 to 50 ft. wide, and assays from 1 to 20% tungstic acid. The mine is owned by G. W. Carty, P. V. Sanders, Carl Stoffelt, and George Farris.

The Hatch lease has completed the tramway from the Buckskin National to the mill, and construction of the plant is proceeding rapidly. Development continues highly pleasing. The Gayer & Defenbaugh lease has driven its adit 90 ft., and expects to intersect the Buckskin National vein within 80 ft. This lease has also started work on a block of ground in the Buckskin Mary.

Golconda, August 5.

LINCOLN COUNTY

PROCE. On September 1 the Prince Consolidated pays 5c. per share, equal to \$50,000. The gross yield for the first quarter of 1916 was \$294,643. The output of ore is 12,000 tons monthly. The new tailing-treatment plant at Bullionville is at work.

Development in the Hamburg mines near-by is reported to be improving. Thirteen cars of ore have been shipped, netting \$15 per ton. Machinery is to be installed.

NYE COUNTY

(Special Correspondence).—The Ralston Mining Co., recently formed with 1,000,000 shares, has acquired control of the K. C. group, adjoining the East End mine, for a reported consideration of \$18,000. The ground is east of the Halifax mine. It is stated that extensive work will be started shortly, and considerable machinery installed. Charles E. Perry is president; William Foreman, vice-president; T. A. MacDuff, secretary-treasurer, with J. H. Evans and R. J. Highland, directors.

Tonopah, July 31.

TOSORAN. Last week's output of 10 mines at Tonopah amounted to 9662 tons valued at \$199,996.—From its final clean-up for July the West End shipped 67,388 oz. of bullion. —The Extension has resumed development, after 60 days' idleness, in the Victor mine. At \$60, 1140, and 1200 ft. in the Sand Grass claim, the Tonopah Mining Co. is doing considerable work. A large new hoist is to be erected at the shaft.

WHEELING PLATE COUNTY

(Special Correspondence.) The Nevada Consolidated will average 12,000 tons per day during August, of a better grade than usual, just under 25 copper. On the surface of the Ruth mine, the company is mining some 50 and over carbonate ore, which is found by opening some of the iron-quartz veins, wherever carbonate stain is found. A considerable tonnage is being obtained in this manner, part going to the McGill plant for direct use in the converters for its silica content, and part to Utah smelters. Work has been commenced to increase the crushing capacity, all material having been ordered. Some of the Wilfley tables are being double-decked to take care of the increased tonnage.

The Consolidated Copper Mining and Smelting Co. has four drills at work.

The tungsten industry is quiet. The Independent company, after spending about \$100,000 on a complete plant, has shut down indefinitely. The Consolidated Tungsten Co., just south of the U. S. T. Co., has also closed. The Nevada Scheelite Co. (Minerva property) is mining and selling some ore to the U. S. T. Co.—Tilford brothers are running the two stamp mill, selling the product to the same company. It is expected that the U. S. T. Co. will have to close as soon as its present contract with the Midvale Steel Co. expires. Present prices are too low.—The Tungsten M. & M. Co. is running steadily, and making a high-grade concentrate. The company has large ore-bodies, cheaply mined, and it can make a profit at present prices. Some property in this vicinity has been bonded recently, the principals being unknown.

Ely, August 1.

NEW MEXICO

Socorro County

(Special Correspondence).—The Socorro Mining & Milling Co. produced 19 bars of gold and silver bullion and a large quantity of concentrate during the first half of July.

Delivery of machinery for the hydro-electric power-plant of the Socorro Power & Lumber Co. has been promised early in January, and it is now thought that the plant will be in commission by April. It is designed to generate 250 horse-power.

M. L. Nanqu, operating a fleet of oil and freight trucks between Silver City and Mogollon, reports a loaded truck-mile cost of \$0.341, based on a total of 5236 truck-miles and an average load of 6500 lb. It is divided as follows: repairs, gas and lubricating oil, \$0.023; tires, \$0.028; labor, \$0.062. The average mileage per set of tires was 1396. The grades exceed 2% for short distances in a number of places.

The proposed road from Clifton, Arizona, to Mogollon is again receiving consideration. It is understood that the Arizona factors will construct a first-class highway to the State line, and the Mogollon interests are now surveying from the Silver City road at Cactus Flats to determine the feasibility of the route. It is said the distance to railroad would thus be shortened by 20 miles with a reduction of \$5 per ton in freight charges. As the in-and-out freight for this district amounts to many thousand tons yearly, the saving would be appreciable.

Mogollon, August 1.

OKLAMOYU

Orlowski Company

COMMERCE. The Croesus and Bethel, each of 200-ton capacity in 10 hours, three miles north of this place, have made their initial 'turn-ins' of concentrate. Miami people control the properties.

In the Oklahoma field the Lehigh & Zinc Co. is to employ 50 drills in prospecting its 3000 acres of land near Picher.

SOUTH DAKOTA

$$L_{\infty}^{\infty}(\mathbb{N}; \mathbb{R}) \cong C^*(\mathbb{N}) \cong \ell_{\infty}(\mathbb{N})$$

FERRON. At the Works No. 1, etc., in addition to mining 500 to 600 lb. of wolfram daily, the mill is supplied with 250 tons of gold ore each year or ten.

(T.M.)

11. (C)

There is a thin line between the two. The difference is a total of 100,000 barrels a day, or the equivalent of about one-third of U.S. oil production. The difference is collected with 173 cents per barrel, or 1.73 dollars per barrel. The difference is 173 million dollars a day. The difference is 62 billion dollars a year.

and determined by the following equation: $\text{Ea}(\text{kJ mol}^{-1}) = 10.5 \log A - 16.1$ (Shen et al., 1997).

20 ft. of ore worth from \$20 to \$50 per ton. The daily output from the mine is 50 tons.

EUREKA. The superintendent of the Chief Consolidated Mining Co., Cecil Fitch, reports as follows for the first half of 1916:

Development, feet	9,692
Ore shipped, tons	42,144
Gross value per ton	\$30.08
Net profit	\$355,702

The ore averaged 0.124 oz. gold, 20.02 oz. silver, 11.79% lead (on lead ore), 1.95% copper (on copper ore), and 30.36% zinc (on zinc ore). Flat deposits between 600 and 800 ft. yielded a considerable part of the output. A new 'system' of ore has been developed at 1800 ft. Dividends absorbed \$88,182. The balance is \$381,589. At present production is curtailed owing to ore congestion at smelters.

It seems that the smelter situation in Utah is improving, and in a short time the Tintic district mines will be able to market their normal quantity of ore. Generally the district is prosperous.

PIUTE COUNTY

MARYSVILLE. Grading for the new potash plant of the Florence Mining & Milling Co. is progressing on a ranch south of the D. & R. G. railway depot.

The Log Cabin mining district is 11,000 ft. above sea-level, and almost above timberline.

SALT LAKE COUNTY

ALTA. On August 10 the South Hecla company distributes \$40,000, its initial dividend. The daily output of ore is 50 tons. Machine-drills are being installed. Power drills are being increasingly used in the Cottonwood districts, replacing the 'single-jacker' and hand work.

BINGHAM. The Bingham Coalition Mines Co., a new Boston concern, represented by G. A. Packard, has taken over the Utah Development, Massasoit, and Butler Liberal claims, also the Markham mill. The properties are fairly well equipped and developed. Lessees have made good profits in the past.

Owing to lower prices prevailing for copper, employees at the Utah Copper Co.'s mills had their wages reduced 25c. per day last week.

SUMMIT COUNTY

During July the Park City mines shipped 7780 tons of ore and concentrate worth \$350,000. About a dozen properties contributed.

WASHINGTON

OKANOGAN COUNTY

CHESAW. The British Columbia Copper Co. has taken a 24 months' bond on the Ramshorn and Cariboo mining claims on Copper mountain, five miles north-east of Chesaw. The mine is to be opened at once. A tramway to carry ore from the property to the Great Northern line, a distance of over 4 miles, is contemplated.

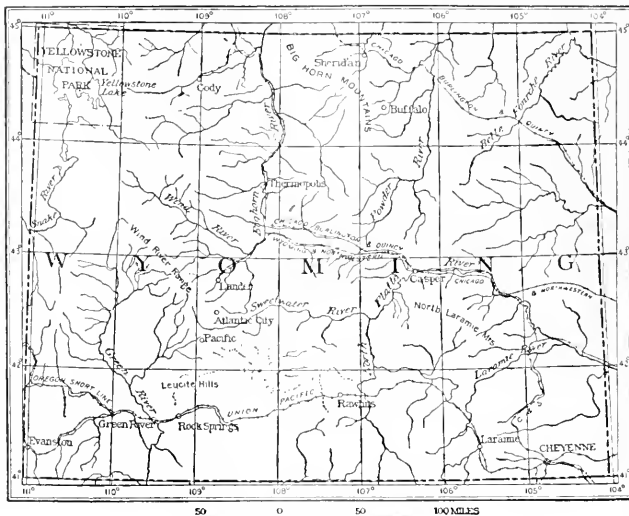

STEVENS COUNTY

CHEWILAH. The United Copper mine is producing 300 tons of ore daily, soon to be increased to 400 tons. Tailings is to be re-treated. A motor-truck and trailer carries ore and concentrate to the railroad.

WYOMING

In Bulletin 626 of the U. S. Geological Survey, the Atlantic gold district and the north Laramie mountains of Fremont, Converse, and Albany counties, are described by Arthur C. Spencer. With maps the publication covers 85 pages. Eleva-

tion of the Atlantic district is 7683 ft. It is 25 miles from a railway. Rocks are crystalline schists, in layers with north-east strikes and steep dips. Diorite intrusions are most abundant. Placer gold was discovered in the Sweetwater district in 1842. Small stamp-mills—12 with 161 stamps—were erected to crush the gold quartz by 1871. It is estimated that to 1911 placers yielded \$1,725,000, and lode mines \$4,137,000. The bullion is 850 fine. According to the State geologist, L. W. Trumbull, the veins are found in the schists, diorite, andesite, and in one case, in granite. On account of lack of near-by rail transport the immediate outlook for a general

MAP OF WYOMING.

revival is not encouraging. The veins are considered to persist in depth. Development, ore treatment, transport, and cost of power are the main considerations for success here. Most of the alluvial gold has been won by working in a small way. Recent production has been small and sporadic. The small gravel deposits offer little promise for the future.

In the north Laramie mountains there has been a search for copper ore, but the prospects opened so far do not seem encouraging. Chromite, magnetite, and asbestos occur, but not in large quantities. Details are given of some of the properties developed.

CROOK COUNTY

BEAR LODGE. The Warner Peak Mining Co. has resumed work in this district. The 5-stamp mill will be used to test the value of the ore.

CANADA

BRITISH COLUMBIA

On August 15 the Rambler-Cariboo Mining Co. pays 1c. per share, equal to \$17,500. This makes \$70,000 for the current year.

ONTARIO

PORTFOLIO. Good progress is reported on stamp-mill and cyanide-plant foundations at the Hollinger.

A report on the reserves of the Dome Lake mine by the manager, G. G. Thomas, shows that the total is \$2,600 tons worth \$1,246,500, to a depth of 600 ft. Indications point to persistence below the bottom level. The shaft is to be sunk to 600 ft. The enlarged mill will treat 200 tons daily.

Recent Patents

1,189,830. METALLURGY. Henry Swift Kimball, St. Louis, Mo., assignor to American Zinc Lead & Smelting Company, Boston, Mass., a Corporation of Maine. Filed Feb. 4, 1914.

1. The method of promoting and insuring liquefaction by condensation of a metal from a gas thereof, which consists in subjecting the metallic gas when at or near the temperature of condensation, to a field of electric stress, thereby accelerating the agglomeration of liquefying particles and preventing individual oxidation thereof.

1,186,617. EXCAVATING AND LOADING MACHINE. Henry H. Tatboys, Duluth, Minn., assignor of one-third to Alexander M. Gow and one-third to Stacy H. Hill, Duluth, Minn. Filed Feb. 10, 1914. Serial No. 817,774.

1. An excavating and loading machine, including a supporting frame, a transverse shaft journaled thereon, a vertically swinging hoisting arm rigid with the shaft and carrying a dipper, a wheel loose on the transverse shaft, an operative connection between the wheel and the dipper, counter-shafts journaled upon the supporting frame and arranged parallel to the transverse shaft, gearing positively connecting one of the counter-shafts and the hoisting arm, gearing positively connecting the other counter-shaft and the wheel, and independent motors geared to the respective counter-shafts for simultaneously swinging the hoisting arm and dipper to impart a crowding movement to the dipper and swing the hoisting arm upwardly and rearwardly to discharge at the rear of the machine.

1,188,705. PROCESS FOR THE RECOVERY OF METALS FROM ORES AND THE LIKE. Charles S. Vadner, Butte, Mont. Filed Feb. 14, 1916.

1. The process which consists in recovering manganese and other metals from naturally oxidized or sufficiently roasted sulfid ores containing manganese and other metals by spraying the finely ground pulp of said ores into sulfuric fumes containing sulfurous gases, oxidizing the solution and riddling the solution of other metals contained therein by precipitating same from the cold solution by means of a sufficient quantity of finely pulverized calcium carbonate and recovering the manganese.

Obituary

EDWARD FORGER THORNTON died at Berkeley on August 6 at the age of 73. He was a native of the State of New York and a graduate of Yale in 1868. After graduation he came to California and during his long and honorable career took a leading part in the mining industry, along the Mother Lode. In 1885 he joined A. D. Day & McNamee in opening the Canyon mine in Calaveras county. Later he became one of the best controllers of the property in Amador county. He was a partner in the El Dorado copper mine and was manager for several years in the development of the Central copper at Buena Vista, Amador county. His many affairs and mining operations showed that he was a successful and a keen desire for profit leading. He is survived by a wife and five children.

THE METAL MARKET

METAL PRICES

San Francisco, August 8.

Manganese: 50% product, f.o.b. cars California, ton.....	12.00-16.00
Magnesium: crude, per ton.....	7.00-9.00
Molybdenum: 50% and over, per pound.....	0.60-1.15
Tungsten: 60% WO ₃ , per unit.....	20.00

At Boulder, Colorado, the Primos Chemical Co. has made a new scale for its tungsten lessees, who were paid \$12 to \$20 per unit. Ore containing from 3 to 32% WO₃ is to receive \$8 per unit, plus 25c. for each 1% above the 32%.

New York, August 2.

Antimony: The market is uncertain, and business difficult, in view of the situation in the metal. The nominal quotation is \$1.25 to \$1.50 per unit.

Tungsten: Buyers and sellers are still far apart. It is reported that one company declined to accept \$27.50 per unit for high-class scheelite, holding for \$30. Small lots are said to have sold in the West as low as \$20 per unit, but these sales involve only hundreds of pounds, not tons. Large quantities could not be purchased at that figure. The market for ferro-tungsten is quiet at around \$5 per pound of contained tungsten. Near June 1 it was quoted at \$7 to \$8.

EASTERN METAL MARKET

(By wire from New York.)

August 8.—It is reported that copper is being bought for export; lead is dull and easy; spelter is dull and weak.

The past week's prices seem to indicate speculation, with a firm undertone. China has been a factor for some time, and is expected to continue so. The moratorium proclaimed in that country may result in silver moving to the Treaty Ports; then sales to India and London. The permanent currency requirements of the country must also be considered. Shipments of silver from London to India up to July 19 total £1,052,500, against £2,810,000 in this period of 1915.

Eastern Metal Market

New York, August 2.

The best showing made last week was in lead, for which there was an active demand for carload lots to be delivered promptly—an indication that consumers' reserve stocks are low. Prices, however, declined, and there is still a feeling that the market must come down to start any heavy movement.

Copper has a much better undertone, and is higher, as a result of the absorption of re-sale metal, and the feeling that the time is near for the large producers to announce a price which will interest consumers.

Zinc is extremely dull and lower, with betterment depending on the brass mills replenishing their supplies.

Tin is quiet at well maintained prices, but the outlook is not favorable for the dealers and brokers, because of the large available supply especially of Banca which is offered at concessions.

Antimony continues stagnant despite lower prices.

Aluminum is dull and unchanged at 58 to 60 cents.

The large orders which have been placed for 6 to 12-in. shells in the past 10 days will not help the metals to any great extent, inasmuch as they are of steel and do not require brass casings. Inquiry for the steel, amounting to several thousand tons, is before the trade. Export buying of steel products is heavier than at any time heretofore, and if it continues will adversely affect the domestic consumers who delay too long in covering future needs.

Pig-iron production in July was 3,226,719 tons or 104,088 tons per day, against 3,211,588 tons in June, or 107,053 tons per day, a falling off of 3900 tons daily. Weather conditions and repairs occasioned the falling-off.

Heavy lathes for shell making are in great demand.

COPPER

The market is stronger, not because there has been any buying of large proportions, but because the metal in second-hands is gradually disappearing; and more particularly because of a feeling that the time is drawing near when the leading producers will take action to stimulate business. Their quotations for months have been of a nominal character, and their attitude one of content in executing the huge contracts on their books. It is expected, almost any day now, they will fix a price at which business will go forward in fourth quarter and next-year deliveries. The better tone of the past few days caused prices to advance from 25 to 26.25c, for spot electrolytic. September electrolytic is around 25.50c, and November around 24.75c. Quotations have anything but a narrow range, and all that will steady the market is some indication of what price the big producers are willing to make. Lake is nominally quoted about 1c. higher than electrolytic. Copper for delivery in the first quarter of 1917 can be had around 24 to 24.50c. Meanwhile, near-by metal is rather scarce. The president of the Crocker-Wheeler Co., at Amper, N. J., S. S. Wheeler, manufacturer of electric motors, and a large consumer of copper, in commenting on the copper situation said: "I do not think that the present high price of copper will continue. But it will be a long time before it returns to its former level of 15c. How could it do so in the face of the unprecedented consumption that is still going on? Granted that production in America is greater than ever, most of this is under contract before it is shipped from the smelters, and there are practically no accumulations of metal to be found in middle-hands." He went on to say that many manufacturers had turned to substitutes for copper, but that they would return to its use when normal conditions are restored. The London market for spot electrolytic yesterday

was £125 against £122 a week ago. Exports in July totaled 35,018 tons, a satisfactory quantity.

ZINC

Another slump has hit zinc, and the market is dull and weak. Prompt and August were quoted yesterday at 9.25 to 9.50c, St. Louis, and 9.50 to 9.75c, New York, and it is probable that these figures might be shaded. September was about 9c, St. Louis, and last quarter about 8.50c. Brass-mill special is easily obtainable at 10.50 to 11c. The London market declined 25 yesterday, dropping from £60 which was the spot quotation a week ago. Not much change in the situation is looked for until the brass mills draw near the end of the contracts under which they are now being supplied with metal, and this may not be for a few weeks. Meanwhile, it would not be surprising if the metal dropped to a level in which some of the newer and smaller producers would find little profit. It is hinted that some of the strength of a week ago was due to a few interests which were short, and whose endeavors to get metal sent the market up and created a short-lived scarcity. Plenty is to be had today. Exports in July were large, amounting to 7979 tons. The new shell orders recently placed are all for the large sizes which do not require brass casings. Japanese spelter is becoming more of a factor in this market as well as abroad. Sheet zinc is unchanged at 15c.

LEAD

Fair activity has been shown in this metal in the past week, and these are indications that a movement of importance is not far away. The A. S. & R. Co. adheres to its quotations of 6.50c, New York, and 6.42 1/2c, St. Louis, and declares that it is taking business at these prices. The trade cannot understand the statement of the big company, in view of the fact that the smaller producers, all of whom have been taking orders, are quoting as low as 6.20c, on spot business, and down to 6.10c, for September. A notable feature in the past week is that the call has been principally for carloads of prompt shipment, an indication that consumers' reserve stocks are running low, and it is believed that should the leading interest drop to 6c, New York, heavy buying would ensue. Interspersed with the buying referred to were some fairly large export orders. The business done was handled almost entirely by the producers, dealers and second-hands doing little. The spot quotation at London yesterday was £28 7s. 6d. against £28 5s. a week ago. Exports in July totaled 2541 tons.

TIN

Business was fair on one or two days in the week, otherwise the market has been dull. The large stock available does not indicate strength for the near future. Deliveries into domestic consumption in July totaled 4172 tons, of which 832 tons came to the East via Pacific port. In stock at London on July 31 was 5928 tons. About on August 1 was 626 tons. The market, so far as the sellers are concerned, is adversely affected by the large quantity of Banca tin here and which, as usual is selling at substantial concessions from the price of Straits tin. Spot Straits was quoted yesterday at 78s. while Banca has sold at 37c.

ANTIMONY

This metal presents a similar picture. A few brands are down to 13c, duty paid, but still there is no demand. Some of the holders are said to possess stocks which they sold 30c per lb. The anxiety of the owners of such metal to dispose of their stocks, despite the fact that the market price is at a considerable loss, is likely to bear down the market even more than the lack of demand.

Recent Publications

COEUR D'ALENE MINING INFORMATION, 1916. Compiled by Wm. Wagner of Wallace, Idaho, between April 15 and June 15, 1916. P. 174. Index. May be obtained through the MINING AND SCIENTIFIC PRESS. Price, \$4.

The Coeur d'Alene mining district includes Shoshone county, Idaho, and the western part of Sanders and Mineral counties of Montana. It covers a considerable area, and contains many well-known lead-silver and zinc mines, as well as minor properties yielding copper, gold, and antimony; in fact, the Coeur d'Alene is one of the most important regions in the country. This little pocket-book has been carefully compiled and arranged. Alphabetically are given the names of 336 companies, their respective capital, officers, situation, and brief notes on the property. Several pages are devoted to production and profits; also something on the Wallace Exchange. We consider this a useful work, right up to date, although a map would have added to its value.

Industrial Notes

Information supplied by the manufacturers:

In Price List No. 65 the CHAIN BELT Co., of Milwaukee, gives the cost of its 'Mogul'-steel bushed chain-belt, 'Durex' combination chain-belt, malleable iron elevator-buckets, and sprocket-wheels for detachable chain-belt.

The 'P. & H.' single-line grab-bucket of the PAWLING & HARNISCHFEGER Co., of Milwaukee is described in Bulletin 101. It is made of the best steel, with good mechanical details, and for handling sand and other fine material the machine has proved satisfactory.

The SULLIVAN MACHINERY Co., of Chicago and London, has established an agency in Holland with Messrs. Petrie & Co., Heerengracht, 141-145 Amsterdam, as its special representatives, who will sell the Sullivan products in the Netherlands. This new arrangement replaces the Sullivan agency previously at the Hague.

The INGERSOLL-RAND COMPANY has issued a catalog in Spanish under the title 'Productos de la Ingersoll-Rand.' This is attractively and well bound, and contains 124 pages replete with illustrations of descriptive matter and tabulated data. It should be of great service to Spanish speaking users of pneumatic machinery.

The third number of 'Roebeling Wire Rope,' the technical wire-rope bulletin of the JOHN A. ROEBELING'S SONS Co., Trenton, N. J., has been issued. It contains information on aerial wire-rope conveyors (continued), the right and wrong way to measure wire rope, the oldest suspension bridge in America, the Roebeling galvanized drop-forged wire-rope clip, wire-rope practice, incline planes, Roebeling wire-rope slings and ready reference tables. The information given is all of practical value.

The use of oxy-acetylene in cutting and welding metals is expanding rapidly, and like the pneumatic hammer it is difficult to see how engineers could get on without it. In Form W-308, the PREST-O-LITE Co., of Indianapolis has published a 45-page instruction book on this subject, written by H. Sidney Smith and A. F. Brennan. This fourth edition is sold for 50 cents, and will be found thoroughly practical. Details are given of the oxygen and acetylene apparatus, the blow-pipe, flame, preparation of materials, fluxes, actual welding, notes on the metals, and useful hints.

On account of change from steam to electricity, the steam power-plant of the Arkansas Valley plant of the American Smelting & Refining Co., at Leadville, has been purchased by the MORSE BROS. MACHINERY & SUPPLY Co., of Denver, and will be removed to its Denver warehouse for re-sale. The Lord Byron mill at Sagar Loaf, Colorado, is being dismantled by this firm and shipped to Denver. The Flint mill near Rollinsville, Colorado, erected two years ago, operating three weeks as a cyanide-plant has been purchased also. The Colorado & Eastern railway, a line running out of Denver to Seranton, Colorado, was recently purchased by the firm, which will dismantle and ship all the rails, locomotives, etc., to Denver for re-sale. The large plant at Leadville known as the Yak mill, situated near the portal of the Yak tunnel, was recently purchased. This was a 500-ton zinc-lead mill equipped with crushers, rolls, roasters, dryers, Cleveland-Knowles magnetic machines, tables, etc., all electrically driven. The original cost of the equipment was over \$200,000. The Geyser mine at Westcliffe, Colorado, equipped with the largest hoisting engine in the State and a complete boiler-plant, compressors, rails, cars, drills, pipe, etc., is being dismantled by the firm for shipment to Denver.

At the Buckeye Belmont mine, Tonopah, recent tests on the Dreadnaught drill were of considerable interest.

EDITORIAL

T. A. RICKARD, Editor

ANNOUNCEMENT of the resignation of Messrs. William B. Phillips, as President, and F. W. Traphagen, as Professor of Metallurgy, in the Colorado School of Mines draws attention again to the mishandling of this useful institution. When will the people of Colorado take steps to put the control of their School of Mines in good hands and take it out of petty politics?

POLITICAL discussion of the Mexican mess during the presidential campaign will have one good result: it will give our people an intelligent idea of the conditions in Mexico and of our responsibilities in the matter. Thus it should prepare the way for a consistent policy. The nomination of Mr. Franklin K. Lane on the Conference Commission has given keen satisfaction in the West.

MORE crude petroleum was marketed in the United States during 1915 than in any previous year, according to final figures just issued by the U. S. Geological Survey. The total was 281,104,104 barrels, valued at \$179,462,890. This is a 6% increase over the output in 1914. Prices were lower, however, the average for the country being 63.8 cents, against 80.6 cents per barrel in 1914. Only in Colorado and Wyoming did prices improve. At the present time quotations are rising steadily, and prospects of the industry are brighter. In 1915 California had to give way to Oklahoma for first place on the list of producing States.

METALLURGY nowadays wins more than one metal, sometimes three or four, out of an ore, so that it becomes difficult to decide under what category to classify a mine. For instance, in 1915 the group of copper mines in Shasta county, around Kennett, California, yielded 315,549 tons of ore from which was won

\$477,684 in gold	or \$1.51 per ton	
396,183 " silver	" 1.26 " "	*
3,772,218 " copper	" 11.96 " "	
1,022,722 " zinc	" 3.24 " "	

the total being \$5,668,897 or an average of \$17.97 per ton, as against a total of \$3,087,279 and an average of \$12.70 per ton in 1914.

IN a report recently written on a Californian mine we find the following: "In a rather hurried survey of your vast estate, taken from the back of a mountain pony, I saw many evidences that you have a valuable property, quartz croppings on hills and mountain tops, in gulches and canyons, and almost everywhere was seen the remains of extensive placer mining." This is

out of date, of course. Twenty or thirty years ago it was not so improper to inspect mines from the carriage deck of a mule or to appraise an ore deposit from the small end of a telescope, but the naivety of the gentleman is to be commended. He deceives nobody. His predecessors in the act of seeing mines where only holes exist were less scrupulous.

MINING men are returning to Mexico, despite the lack of protection from the Administration at Washington. Passports are refused by the State Department, yet the managers and owners of mines are going back because they know that this affords the only chance of protecting their property. On another page we publish the exchange of telegrams between a mining engineer and the State Department. We are informed that other engineers have had exactly the same experience, being told peremptorily that they must leave Mexico or stay at their own risk. It was the threat of war that made it dangerous to stay and not interference from the Mexicans, so say those operating on the West Coast more particularly.

SPELTER had a flutter during the last two weeks of July, rising from 9.25 to 10.50 cents, but soon receded to a new low point in the present market, namely, 8.25 cents. One smelter in Kansas is shutting down a block of furnaces, while others are not buying more ore than necessary. A mid-year statement on the metal has been issued by the U. S. Geological Survey, covering the first half of 1916. The supply totaled 330,922 tons, including 14,253 tons of stocks at the beginning of the year, 267,449 tons from domestic ore, and 48,756 tons from foreign ore, also 464 tons imported. There was withdrawn 20,197 tons for foreign export, 58,007 tons for domestic export, while stocks on June 30 were 21,000 tons. The apparent consumption was 228,700 tons. In addition to the retorts erected at the middle of the year, 193,696, there were 22,188 building or contemplated.

CONFUSION still exists among prospectors as to the basis on which ores of tungsten are bought and sold. It is possible to misunderstand, for instance, the meaning of "concentrate of 50% tungsten oxide" and to think erroneously that this means concentrate consisting of 50% scheelite or wolframite, which contains only about 60% of tungstic oxide, or tungstic acid. The confusion arises from the fact that tungstic oxide, which is the acid radical WO₃, cannot be visualized by a miner. He understands that a 10% zinc or copper concentrate means 10% of zinc or copper, rather than 10% of sphal-

erite or chalcocite, because he has seen zinc and copper in their metal forms. But he never has seen any tungstic oxide. A price of \$30 per unit of tungstic oxide means \$30 for each percentage, or 1% or 20 pounds. A price of \$30 per unit for 60% concentrate means \$1800 per ton for concentrate containing 60% tungstic oxide.

Stamp v. Ball-Mill

This case is on trial in the great assize of experience. We might have headed our article 'The passing of the stamp-mill,' but that heading has been used so often during the past twenty years and the stamp-mill has shown such stolid refusal to pass that it seemed wisest not to tempt the refutation of events so confidently. Any mechanical device that has withstood the whips and scorns of scientific observers for a time longer than the lives of most of its critics, and that still persists in holding its ground despite the onslaughts of competing inventions of greater ingenuity, must have sterling merit. Even its best friends, however, do not claim that as a crushing machine it is a model of efficiency, for the ratio between power consumed and work performed suggests a radical defect. The more frequent claim for the superiority of stamps is their simplicity both of construction and operation.

People are apt to regard the things they understand as simple, those they do not understand as complex. Is not this the real reason for the alleged simplicity of the stamp? Consider the innumerable adjustments that have to be made and the tendencies to a break-down. The foundation-bolt nuts must be tightened frequently; the screens watched with a vigilant eye; the chuck-blocks lowered and the false dies replaced as the shoes and dies wear down; the shoes and dies themselves must be replaced when worn out; broken stems have to be replaced and welded; tappets must be set so as to compensate for the wear of the crushing surfaces; the lining of the mortar is abraded; cam-shafts break, and so on. The 'fingers' that 'jack-up' the stamps have to be manipulated with careful skill; the clean-up inside the mortar is a time-wasting nuisance. The indictment becomes formidable.

Designers allow $2\frac{1}{2}$ horse-power for the operation of a stamp weighing 1000 pounds dropping 100 times per minute from a height of 6 inches, although the actual energy, as measured in foot-pounds, is equivalent to only 1.6 horse-power. What the efficiency is, based upon the power required for crushing ore in a theoretically perfect device, we do not know. Ordinarily, the capacity of a stamp such as is mentioned above may be taken at from 1 to 5 tons per day of 24 hours, with $1\frac{1}{2}$ -inch feed crushed to pass a 30-mesh screen, or not less than half a horse-power per ton of ore milled. The low output of the stamp is due in great part to its inability to discharge the crushed product when once reduced to the desired fineness. Various devices and improvements in design have been offered from time to time in order to overcome this defect. Multiple-discharge mortars of many

types have been invented, but, while they increase the capacity, it has been done at the expense of what is really the greatest point in favor of the stamp-mill, its service as an amalgamating machine. This, combined with the ability to effect a greater proportionate reduction in a single stage than any other device, plus the familiarity of the average mill-man with its many vagaries and complexities, constitutes the real reason for the hold it retains upon the affections of the miner.

It is not to be supposed that the stamp-mill has been able to retain its astonishing supremacy during all these years without a struggle. A bewildering array of competing apparatus has been introduced, good, bad, and indifferent. Every form of mechanical motion under the sun has been tried, from high-speed centrifugal machines that pulverize everything, including themselves, in no time at all, to some of the so-called pulverizers that gently massage the rock in a leisurely manner until it finally falls apart from sheer weariness. Some of the various roller-mills have found a comparatively limited field of application in the crushing of soft ores, or in performing their part in one stage out of a three or four-stage crushing operation. That is why the stamp more than held its own until the introduction of the cyanide process started a revolution in milling practice that shook the old battery to its very foundations.

It will be remembered that, in the development of cyanidation, leaching came first. Then, owing to the long contact required for taking the coarse gold into solution, fine-grinding was introduced, with its inevitable sequel, filtration, and with it the more or less complete rejection of amalgamation as one of the means of extracting the precious metal from the ore. When the need for a simple and effective fine-grinding apparatus was manifest, the engineer, casting about for something ready-made that would fill the bill, jumped over the fence into the field of cement machinery and lifted the tube-mill bodily into the domain of ore-dressing. It was soon discovered that the highly diluted pulps produced by the stamp did not give the best results in tube-milling, so pulp-thickening and de-watering devices were employed, until finally the classifier was introduced into the fine-grinding circuit, returning the oversize for re-grinding and sending the fine product to the cyanide annex for the extraction of its metallic contents. And still the old-fashioned battery thundered in the canyon, taking the product from the primary crushers at about 1-inch cube and delivering a 10- or 20-mesh product to the tube-mills. In a few instances, rolls and Chilean mills were substituted, but, generally speaking, our friend the stamp, after five hundred years of usefulness, continued to prove his marvellous adaptability by being ready to meet the latest of emergencies.

It would be interesting to know just what started the ball-mill epidemic. Here is another instance of borrowing the implements of the cement industry; in fact, as far as the crushing department is concerned, cement machinery has been annexed almost bodily by the metal miner. However, the ball-mill as a competitor of the

stamp is now an insistent fact, and it really begins to appear as if our old friend before long will have to join the innumerable caravan of the obsolete, retiring with horse-drawn vehicles and sedan chairs into the limbo of discarded things. There is nothing irrational about the popularity of the ball-mill. Speaking of simplicity, here is the real thing! Take a hollow shell; put a head at each end; provide means for rotating it at comparatively slow speed; punch a hole in one end for feed, and in the other end for the discharge; line it in such a way as to afford a readily removable shell on the inside; throw in a few tons of balls; and there you are; no hair-trigger adjustments, take-ups, or any other form of nuisance attending the operation of a stamp-battery. Each ball is a stamp that crushes and grinds; the rotary movement of the shell lifts the balls and drops them upon the pulp, which is actuated from the feed to the discharge by perfectly natural forces, and is gradually comminuted meanwhile. The coarse product will gravitate to the periphery, while the finer particles will work their way to the centre of gyration, in other words, the centre of the mill, and finally escape through the hollow trunnion at the discharge end. The pulp is agitated by the balls so as to be kept constantly stirred, breaking every particle. As for results, here are some typical figures made public by a well-known manufacturer of ball-mills. A mill in Canada had been operating eighty 1250-pound stamps and crushing 800 tons per day through 2-inch screens. The consumption of power per stamp, therefore, would appear to have been about 3 horse-power, or 0.3 hp. per ton of ore milled. By way of experiment, one ball-mill was installed, and, after four months' trial, it proved itself able to crush 498 tons per day, using 113.2 horse-power, with a charge of 28,000 pounds of balls, or 0.225 hp. per ton of ore milled. The floor-space occupied was about the same as would be required by ten stamps, or one-fifth that taken by the stamps per ton of ore milled. And there were no counter-shafts, pulleys, belts, tighteners, broken stems, cam-shafts or tappets to set up, or any of the other things that characterize the 'simplicity' of the stamp. That is also the opinion at Jumeau, where ball-mills are displacing stamps. The time has come to revise our opinions.

The Business of Mining

In a recent issue we published a commencement address delivered by Mr. J. R. Finlay before the Colorado School of Mines; on another page we reproduce the larger part of a similar address made by Mr. W. R. Ingalls before the Missouri School of Mines. These two engineers, besides giving nearly simultaneous lectures to our young men on a kindred subject, both served as secretary and president successively of the Mining and Metallurgical Society of America, an organization that has proved more influential than representative. Of course, the address by the editor of the *Engineering & Mining Journal* is as interesting to older men as it must have been to the particular

part of the audience for whom it was primarily prepared. Mr. Ingalls regrets the absence of regulations disciplining the mining profession. The Mining & Metallurgical Society introduced some semblance of regulation by restricting membership and it is conceivable that had it not been stranded on the shoal of exclusiveness it might have exercised a salutary influence on the profession. But the idea of forbidding a man to practice any profession is one unlikely to come into favor in this democratic country. The ideal of equality of opportunity is too precious to be endangered either by legislative restriction or oligarchic taboo. The definition of 'profession' as given in Webster's dictionary and quoted by Mr. Ingalls is not a good one, but it is good enough to introduce the suggestion of commercialism. Undoubtedly mining is a business, to which the profession ministers, and any mining engineer that expects to succeed must understand the various phases of this business to which his advisory functions are dedicated. Young men with high professional ideals may become disillusioned when they discover that the striking successes are won by financial shrewdness rather than by technical ability; but then comes the test of the true professional man: the love of his work, compensating him for the monetary gain that he sees escaping him. Doctors, lawyers, clergymen are recognized as members of professions because they treat their respective occupations as a vocation, although many of them might enrich themselves readily by selling automobiles, promoting mines, teaching the one-step, or dealing in real estate. So, we presume, there will continue to be simple-minded whole-hearted men willing to remain professional when they might so easily become predatory. However, it is good advice that Mr. Ingalls gives in urging misfits to change their employment. The square peg in a round hole is the type of misdirection. A good sales agent is the superior of a bad engineer. Those are fortunate that find the work for which they are adapted, and it is a splendid characteristic of American life that the change from one occupation to another is so easy and so reputable, affording men the opportunity to discover what they can do best, and giving them a chance to do it. Mr. Ingalls mentions four representatives of the 'generals' of mining. Let us add four representative 'staff-officers', E. P. Mathewson, E. H. Hamilton, Philip Argall, and Albert Burch. And to that we may append four representatives of the 'war council,' the men of proved sagacity in directing the broad lines of a campaign: H. C. Perkins, D. W. Brumton, D. M. Riordan, and E. T. McCarthy. These are merely typical; each reader can add to the number out of his knowledge and acquaintance. It is at least a sign of the times that the famous members of the profession, or business, are to be found in the class of 'generals.' They are men that were technicians until they became connected intimately with big enterprises and then, in some cases almost automatically, they participated in the buying and selling of mines, finally playing a hand in the big 'game,' as it is called in the West, of promotion and speculation. The stories of the late Mar. is Daly and

Mr. John D. Ryan are apropos, for the engineer must learn that the basic purpose of mining is to make money, not to dig holes or to spoil the scenery. We associate ourselves with Mr. Ingalls in his admiration for the work done by Mr. H. C. Hoover. He gave to the cause of Belgium what money could not buy—disinterested service and executive ability of the highest order. But we must demur to the Walsh story of the discovery of the Camp Bird. That story would furnish an excellent text for a commencement address if it were true. It is not. Mr. Ingalls mentions that the account as given by the late Thomas F. Walsh to an admiring class of students was re-printed in the journal of which he is now editor, but the true story was printed in the same journal before he became the editor of it. In 1899, three years after the event, and ten years before the official myth was propagated, Walsh told the present writer, in the presence of Andy Richardson, while all three stood close to the scene of discovery, how he had stumbled upon his fortune. His story, corroborated and corrected by his faithful retainer, Richardson, was recorded on the spot and the gist of it was published in the *Engineering & Mining Journal* of July 18, 1903. If that first published account had been incorrect it is probable that Walsh, or his manager John Benson, or other persons cognizant of the facts, would have corrected it at that time. It is not unusual for the finding of a rich mine to be credited wrongfully to scientific acumen. The simple facts become smothered in romantic details until a gorgeous myth passes current as history, to be retailed even by the discoverer himself, who finally persuades himself that it is true. In the same way W. S. Stratton was given credit for knowledge of chemistry and mineralogy, and, on the insistence of his friends, credited himself with them, although he had pottered around the one conspicuous outcrop in the Cripple Creek district for many days before at haphazard he chipped a piece of the decomposed granite, which proved to assay 19 ounces in gold per ton. Then the millwright graduated as a mineralogist, and in course of time he forgot, as also did his friends, that he had told the true story to a person able to record it. As to Walsh's story, "a slide of reddish pyritiferous porphyry" would be no "indication of gold" in a district where the andesitic mountains are red as radishes; nor does the Camp Bird ore carry tellurides "in circles of glistening black mineral." The thin dark bands consist of fine-grained galena and blende, the proportion of telluride being not only minute, but doubtful. Walsh heard about the 'telluride' long afterward, when Mr. F. L. Ransome had published his report on the Silverton quadrangle. The pink mineral that attracted Walsh's attention on the Gertrude dump was rhodonite; he mistook it for fluor-spar, with which he had become familiar at Cripple Creek and with which he associated the occurrence of gold.

What Mr. Ingalls has to say regarding the play of character in a technical career is well stated. So is the final insistence on the main purpose of both mining and metallurgy—to make money, not to apply geological

theories or to use pretty machinery; in short, as his whole address emphasizes admirably, the winning of the metals from the earth is not a scientific pursuit but a business.

Surficial Signs of Copper

The last of the series of articles on this subject appears in this issue, and we feel confident that our readers will feel under pleasant obligation to Mr. Frank H. Probert for his painstaking and illuminating analysis. The information he has given and the suggestions he has offered can, and will, be put to practical use by those in search of the metal that plays so important a part in civilization, and in the attempt to destroy it. The colors of the landscape, particularly in the South-West, will henceforth have a new meaning for the observant prospector, geologist, and engineer. Yellowness, rather than redness, will attract the eye of the seeker after another Miami or a second Chuquicamata. In his last article, the author, not content with his own observations, has been wise enough to gather the views of a number of engineers closely associated with successful copper explorations, adding thereby to the value of his own conclusions. Another phase of the subject, that of rock alteration, is reviewed, indicating the principal parts played by silicification and kaolinization. Here also Mr. Probert has drawn on the experience of other observers, submitting the opinions of mining geologists connected with important enterprises in Arizona and Mexico. His own successful diagnosis of the Ray deposit affords a striking example of the direct application of geology to mining and illustrates the economic value of these scientific studies. We hope that some of the gentlemen quoted by him will add further to the value of the essay by contributing comment and criticism. We are glad that Mr. Probert should conclude his present writing with a quotation from Mr. R. A. Penrose's paper on 'The Superficial Alteration of Ore Deposits,' for we believe that that particular article did a great deal to stimulate intelligent curiosity in regard to the nature of outcrops and proved of direct value to mining engineers in many parts of the world. That is what Mr. Probert, in turn, will have done. Such publication of individual observation and experience is a contribution to human progress that every man should aim to make, in return for the heritage of knowledge given to him gratuitously by others. We venture to close by referring to a pathetic incident. Among those lost on the *Lusitania* was C. T. Brodriek, a Harvard graduate and a young geologist of the greatest promise. He had been studying secondary enrichment and its allied problems in the Siberian copper mines and elsewhere, and on his last journey he carried with him a mass of invaluable manuscript recording his observations. This went down with the gallant ship when she was assassinated. If he had only had a multiple copy made, or if his notes had been printed, they would have been preserved as a fitting memorial to a truly scientific man and would have perpetuated the work to which he had applied himself so devotedly.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters relating to mining and metallurgy. The Editor will accept expressions of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Americans in Mexico

The Editor:

Sir—The following telegram to the Department of State, and the reply, may be of interest.

TELEGRAM

San Francisco, July 30, 1916

Department of State, Washington, D. C.

I am an American citizen. July 8th left Manzanillo, Mexico, against my wish, after seeing telegram from Department saying 'Americans must leave.' Went to Mexico nine years ago after investigating and finding I had right to go there to live. All I have is in Mexico and remembering exodus of 1914 and the hardships caused have left my wife, mother and two small children at our home in Guadalajara, Mexico, with wife's father who is German. Wishing to return to my home please authorize passport and transportation or failing in this please authorize funds for bringing my family to this country and for our maintenance here and subsequent return to Guadalajara where we have the right to live and be protected as American citizens. There is no war with Mexico and having been advised to abandon the results of our work in Mexico by the State Department does not alter our rights nor the obligations of the United States towards its citizens. Awaiting favor of prompt reply so I may make plans accordingly.

R. S. BURDETTE,
Hotel Sutter.

ANSWER TO ABOVE TELEGRAM

Washington, D. C., Aug. 2, 1916, 2 pm.

R. S. BURDETTE, Hotel Sutter, San Francisco.

Your telegram July 31. Department does not deem it advisable for the present to withdraw the advice previously given American citizens to remove temporarily from Guadalajara district or to make exceptions thereto. Department will be glad to consider advisability issuing passport to you as soon as it is satisfied conditions in Guadalajara district warrant such action. You are in error when you state Department said in telegram Americans must leave Mexico. What it did was to advise Americans to leave Mexico temporarily for their safety. Department has no funds at its disposal that could be used for your maintenance in this country or for your return transportation to Guadalajara. You are further advised that only destitute American citizens in Mexico can be furnished transportation to their homes in United States.

FRANK L. POIK,
Acting Secretary of State.

Before I left Guadalajara, on July 3, the following telegram was received by the Americans remaining in Mexico:

Consular Department informed several hundred Americans in various parts of Mexico intend to disregard this government's advice to leave Mexico. This government feels that it cannot be responsible for any such Americans unless they

leave immediately. Unless they leave now the abilities to assist them in their exit will inevitably be rendered extremely difficult to accomplish. Impress on all Americans still in Mexico districts that they are assuming grave responsibilities if they should elect to disregard this advice.

(Signed) LANSING.

The telegram saying "Americans must leave immediately" I saw on board the *Maryland* at Manzanillo on July 8; for this the State Department denies responsibility in its answer to my telegram. This telegram was shown to me by U. S. Vice-Consul Stadden at Manzanillo on board the *Maryland* in the presence of the captain of that ship. I believe the telegram was signed by Admiral Fullan and both Stadden and the captain of the ship gave me to understand clearly that it came through the State Department and called my attention to the word "must" used in the telegram. I was anxious to go back on shore and return to my home in Guadalajara but decided to leave in view of the telegram and the urging of the Consul and captain.

Comparing my telegram and the reply received one can easily see how discouraging it is to be an American citizen in Mexico. In general, those of us who have lived in Mexico consider our Government's policy grossly inefficient. Through incompetence or stupidity it is causing the ruin of over 90% of the people of Mexico both financially and morally. The richer classes have in large measure moved to other countries, the middle-class has for a long time been living without hope and pawning their little valuables; the poor class has been forced to trade their women and daughters for a bare existence. Hunger makes many men do things that are ordinarily condemned by well-fed human beings.

I do not speak disparagingly of the Mexican people. The conditions thrust on that country, largely by the action of the United States, have made it impossible for many millions to gain a livelihood, and I doubt if the behavior of any other race would be better if placed in the same helpless position through circumstances beyond their control.

It is easy for some one to suggest that the Mexicans should free themselves from these conditions. The problem is a large one, but Mexico would probably have come to a solution before now if our special representatives had been competent and the information they gathered had been acted upon, instead of trying to make the case fit the impossible policy of our administration during the past four years at the cost of thousands of innocent lives while our State Department talks of "humanity."

and dodges all of its real obligations to Mexico as a nation and to its own citizens in and out of Mexico, as well as to foreigners who must be protected if the Monroe doctrine is to hold.

R. S. BURDETTE.

San Francisco, August 4.

The Burden of Mailed Advertising

The Editor:

Sir—With ever increasing volume the desk of the mine manager is burdened with advertising matter that comes through the mail in the form of letters until it has become a nuisance and a pest. Mining men are proverbially up-to-date in their business affairs and constantly on the look-out for improvements in machinery and methods; but this does not mean that busy men give their time cheerfully and patiently to running through a mass of letters addressed to them only to discover that none of it has any particular value for them. They would not give half an hour a day to a book-agent or a peddler; why be expected to give it to a solicitor that gets into the office surreptitiously through the mails? Mining men look to the columns of their professional and trade journals for information as to advancement in the line of mining and ore-treatment; and they look to the advertising columns of these papers for information concerning machinery and supplies that are safe to buy. Some of the largest advertisers in the trade papers are the most persistent solicitors through the mails, but I cannot believe it pays. In an experience of more than twenty years I do not recall buying any sort of an article because my attention has been called to it by a mailed circular. Invariably I consult the columns of the Press or other paper. Somehow that seems to be the legitimate method of soliciting trade. It is open and above-board, and in the long run must be able to stand competition and investigation. Not so the mailed circular, which can make any sort of claims regardless of actual facts. Editors even of high-class journals do not of course guarantee the statements of their advertisers, but they do not long tolerate advertising by unreliable concerns; and thus the appearance of an advertisement in a journal like the Press carries with it a certain air of respectability and worth. The concern publishing it at least keeps good company. The mailed solicitor, on the other hand, comes along like a thief in the night, and even if he is thoroughly honest he bears no signs of a good character. But the worst of him from the busy man's standpoint is his impertinence and his waste of valuable time. He comes in without knocking, plants his feet on your table, and there remains until you can find time to discover whether he has a legitimate right to your time or is an imposter. By law all advertising matter appearing in publications must be specifically marked as such either by form or by label; the law should provide that all soliciting sent through the mails should be plainly labeled 'advertising matter' on the wrapper. The busy

manager could then consign it to the waste basket without loss of time and patience.

R. N. FLETCHER.

Reno, Nevada, August 1.

[We sympathise with our correspondent. The only corrective to the nuisance is a large waste-paper basket, like our own.—EDITOR.]

Cyaniding Flotation Concentrate

The Editor:

Sir—In your issue of June 24, M. G. F. Söhnlein disagrees with sundry points in my article appearing in the issue of April 8, 1916.

Mr. Söhnlein is quite right in what he has to say regarding classifiers and the Frenier pump when used with ordinary mill-pulp. My description of these machines applies only to the treatment of clean sulphide minerals, which is quite another matter.

The Frenier spiral pump can best be applied for low lifts up to 10 ft. in the case of clean sulphides of high specific gravity. However, I prefer a well-designed centrifugal pump (of the Byron-Jackson type), for elevating the sulphide-pulp overflow (200-mesh material) from a Dorr combined hydraulic and rake classifier to the thickeners or agitators. I am certain this arrangement will give the minimum of trouble. The most recent plants for treating concentrate are using the centrifugal.

Belt-bucket elevators have not met with much favor at cyanide-mills treating concentrate. However well designed they may be, it must be admitted that they cause as much trouble as any machine about the mill. Long elevators give more trouble than the short ones. Such has been my experience.

Mr. Söhnlein agrees that "when a pulp is so fine as to pass 100-mesh, pumps are also satisfactory and cheaper to install." Such is the case with a cyanide-mill treating concentrate (clean sulphide from tables, vanners, or flotation) where all the pulp (product to be elevated) overflowing the Dorr classifier will practically pass a 200-mesh screen. What he has to say about the combined hydraulic and mechanical classifier applies only to the usual mill-pulp containing minerals of widely varying specific gravity. His statements do not strictly hold for the classification of a more homogeneous material (clean sulphide) concentrate, at which my article was aimed. The figure of 30 to 35% moisture in the coarse concentrate is too high. This is my mistake. There is every reason to expect a less moisture when the discharged coarse material contains less undersize.

A. E. DRUCKER.

London, July 25.

[Evidently Mr. Drucker's experience with elevators has not been satisfactory, yet in many plants they work well at low cost. In our issue of February 15, 1913, we described an elevator at Goldfield.—EDITOR.]

Synthetic Nitric Acid

By F. H. Mason

The daily papers, from time to time, have been impressing on capitalists the desirability of erecting a plant for the manufacture of nitrates in the United States, and one enthusiastic booster, in a San Francisco daily, pointed out that a nitrate plant and a health resort should be established at the same place, because the former would help the latter by removing nitrogen from the air, and thus leave a more invigorating atmosphere for the invalids. It is not necessary to say here that in the synthetic preparation of nitric acid from the atmosphere more than twice as much oxygen as nitrogen is removed, but the enthusiast need not be afraid that such a plant would injure the Californian climate, for even if a plant were started it would have no more effect on the composition of the atmosphere than the salt-plants on the shores of San Francisco and San Diego harbors have on the salinity of the Pacific ocean.

The American business man is not slow to grasp opportunities, nor does he, as a rule, require to be urged by the daily press; the latter more often trails along in his wake, inaccurately reporting his aims and ambitions and the progress he is making in the industries to which he has turned his attention. We may be assured, then, that there is some good reason why capitalists of the United States have not taken up the manufacture of nitrates from the air. Certainly the reason is not lack of raw material, for it has been calculated that above each square mile of the earth's surface there is some 20,000,000 tons of nitrogen and 5,000,000 tons of oxygen; enough raw material, in all conscience, without taking into consideration the law of diffusion of gases. We know, also, that extensive water-powers are available in both the United States and Canada to supply the necessary energy. We must look, then, for some other cause, and in doing this it will be well to see what has been done in Europe, where plants for the synthetic preparation of nitrates have been in operation for several years.

The preparation of nitric acid from the atmosphere is no new discovery. When Cavendish, in the 'eighties of the 18th century, was making his historic experiments on the composition of water, he noticed that when hydrogen and air were exploded in a eudiometer* the resulting water was invariably acid, but when hydrogen and oxygen were exploded the resulting water was neutral. From this he rightly concluded that the nitrogen, as well as the oxygen and hydrogen, had taken part—though only to a small extent—in the chemical reaction, and, in 1784, he demonstrated this by preparing nitrate of potash by passing electric sparks through equal volumes of oxygen and nitrogen in a globe contain-

ing a small quantity of a solution of caustic potash. It was found to be necessary to remove the nitric peroxide as soon as made—as with caustic potash, for instance—or that already made would be decomposed into its original elements by continued action of the electric discharge, and it is this that has been the stumbling-block that has held back the commercializing of Cavendish's discovery for a century and a quarter. The simple equation $N + O = NO$ is reversible, and unless the nitric oxide made is immediately removed from the conditions that brought about the combination of its elements the reverse equation takes place.

With increased facilities, however, Birkland and Eyde, in 1903, were able to prepare nitric acid from the air on a commercial scale, and four years later they erected a plant at Notodden, in Norway, utilizing a water-power of 40,000 hp.; and other works, using other kinds of furnaces, quickly followed.

The furnaces employed for the manufacture of nitric acid from the air vary considerably, but the object of all of them is to bring the air into intimate contact with an electric arc, for, it is generally conceded, electricity, as well as intense heat, plays an important part in uniting the two gases. In the Birkland-Eyde furnace, the electrodes are two copper pipes, cooled by water, through which a high-tension alternating current of 5000 volts passes; poles of a powerful electro-magnet are placed at right angles to the electrodes at the point where they approach each other, and flare the arc into a disc; this is enclosed in refractory material, and air is blown through the disc-like arc, where it is raised to a temperature of from 3000 to 8000 °C. The gases issuing from the furnace are cooled as rapidly as possible to 500 °, because it has been found that while temperatures above 3000 ° are best suited for the formation of nitric oxide the range between 2500 ° and 1000 ° is favorable to its decomposition. The gases are passed under boilers, where they are used to generate steam, into the oxidizing-chamber, kept at 50 °, where nitric oxide is converted into nitrogen peroxide by surplus oxygen. From the oxidizing-chamber, the gases are passed to a series of absorption-towers, where they pass up through broken quartz and meet a descending shower of water or acid, which converts the nitrogen peroxide into nitric and nitrous acid:

It would appear from the equations that such nitrous acid is formed, but in practice this becomes unstable with increasing concentration, and splits up thus:

*A graduated glass vessel used in volumetric analysis.
EDITOR.

the NO is oxidized to NO₂ as it passes through the towers. The weak acid obtained from the last tower is pumped into the one preceding it, then into the next one, and in this way the tower nearest to the furnace is made to produce an acid of 40 to 60% strength that it used to decompose limestone, forming nitrate of lime, which, after evaporation, is ready for the market.

If the combustion of the air were complete in accordance with the equation

—too much to ask, of course—the gases issuing from the furnace should contain 40% nitric oxide, instead of which if they contain 2.5% of that gas the furnace is considered to be doing unusually good work. The weak point, then, about the process is the inefficiency of the furnaces. The issuing gases from the Birkland-Eyde furnace contain 2% of nitric oxide, many furnaces produce less, few more. One reason for this low efficiency is that the atmosphere contains four parts of nitrogen to one of oxygen while the proportion required for the reaction is equal parts of each gas, so that 60% of the gases passing through the furnace serves no useful purpose, while it absorbs an immense amount of heat. It has been found experimentally that by adding oxygen in the proper proportion to form nitric oxide to the gases entering the furnace as much as 14% of nitric oxide was contained in the gases issuing from the furnace, but this, of course, is impracticable commercially on account of the cost of oxygen.

Here, then, in the inefficiency of the process, seems to be the reason that the American business man has not turned his attention to the manufacture of nitrates. There are innumerable uses for electric power that will bring an infinitely better return, and, now that power can be transmitted economically long distances from where it is generated into electricity the man who develops the power usually looks for a better return on his investment.

There is, however, an indirect method of preparing nitric acid from atmospheric nitrogen that gives greater promise, and seems likely entirely to supersede the direct combustion of the atmosphere. This, like the other, represents the commercializing of knowledge that has been the common property of chemists for a number of years. Soon after the discovery of ammonia it was found that its combustion with oxygen produced nitric acid and water, and as long ago as 1830 Kuhlmann produced nitric acid by the oxidation of ammonia by aid of a catalyst. But in these days ammonia was far too costly for the process to be economically successful. Recently, ammonia has been prepared by a number of different ways, directly and indirectly, from atmospheric nitrogen; it is made by direct union of its elements, the nitrogen being separated from the oxygen of the atmosphere either by fractional liquefaction or by passage over heated copper. By the latter way, an almost oxygen-free nitrogen can be obtained, while the copper oxide formed can be rehabilitated by passing coal, water, or natural gas over the heated oxide. The nitrogen and hydrogen are made to

unite by the aid of a catalyst—generally uranium is used—at 500 to 700° C., and the best results are obtained under a pressure of 3000 lb. A simpler process for making ammonia is that of passing superheated steam over cyanamide, the last having previously been made by passing nitrogen through calcium carbide heated to 800°. Another method of preparing ammonia is that of first preparing nitride of alumina by heating bauxite and carbon in an atmosphere of nitrogen in an electric furnace. The nitride is treated with caustic soda when the following reaction takes place:

By neutralizing the sodium aluminate with acid a pure alumina, that can either be marketed or used for the production of more nitride, is obtained. Calcium and magnesium nitrides also have been used.

The ammonia, by whatever method obtained, is mixed with ten times its volume of air and passed rapidly over a catalyst consisting of platinum, the face of which is covered with platinum black. The preparation of the catalyst is all-important, as if an excess of plating black is present there is a tendency to get the reaction:

instead of the desired one:

The mixed gases are passed through porcelain-lined or enameled-iron tubes into a chamber containing the catalyst where the oxygen and ammonia unite; the resulting nitric acid, water, and nitrogen are led through a series of towers packed with broken quartz or earthenware where the nitric acid is condensed by a stream of acid falling through the earthenware.

When nitric acid is made by the oxidation of ammonia it is usually neutralized with ammonia, forming ammonium nitrate, which as a fertilizer contains 35% of nitrogen, as opposed to 16.5% in sodium nitrate, and which is used extensively in the manufacture of some explosives.

It will be seen, then, that the indirect method has the great advantage that, beside being more economical of power, the site of the plant is not confined to the neighborhood of a huge water-power.

IMPORTS OF CRUDE AND SCRAP ALUMINUM in the 11 months ended May 31, 1916 were only 7,551,063 lb., against 11,978,283 lb. and 14,868,574 lb. for the same periods in 1915 and 1914, respectively. In 1915 imports were 8,534,834 lb., compared with 23,185,775 lb. in 1913. On the other hand, exports have increased. For the 11 months ended May 31, 1916, they were valued at \$5,156,342, against \$2,994,476 and \$1,040,686 in 1915 and 1914, respectively. Decreased imports are a supporting factor of the market, now 58 to 60 cents, and new uses of aluminum continue to be found.

THE URYANHAI PROVINCE of Siberia is considered to be of considerable promise by some English mining men who were investigating the area last year. Asbestos, coal, copper, and platinum deposits have been found, as well as gold.

Surficial Indications of Copper - V

By Frank M. Probert

In the four preceding articles I have attempted to review, in sequence, the factors that influence the outcrop and tend toward the concentration of copper salts to form ore. It is not necessary to summarize the ideas already expressed, although I would again emphasize the fact that metal mines are found in connection with igneous rocks, that these are present in mountainous districts, that conditions favoring fairly rapid circulation increase the possibilities of oxidation and enrichment, and that the erosion of the surface causes a lowering of permanent water-level. These features should be studied, and inferences drawn from topographic and climatic conditions.

In appraising the value of prospective mineral land, there is seldom anything but the bare surface of the ground and the engineer's experience to guide him. It has been said that "analogy is a dangerous weapon in the hands of the inexperienced."¹ It is, but the Latin idiom *"experientia docet"* may be freely translated "experience does it." Examining a new district, with little or no underground development, we must interpret the surface signs by the light of experience. The key to the door of a mine may be found in the outcrop.

The color scheme of the earth's surface defies the palette of an artist; how much more so must it baffle the description of a mining engineer! Still the color or discoloration of rocks is important. I have said that any unusual surface feature warrants investigation. Striking colors, particularly the reds and deep purplish-browns, beckon the prospector. The presence of copper is often denoted by the color of iron oxides, this on account of the universal association of the two metals, the predominance of iron, and the strength of the red as a permanent pigment. The surface coloring of vein outcrops is generally more striking than that of the disseminated deposits because of the greater concentration of metallic salts per unit of area, and again, because most of the 'porphyry coppers' have suffered long continued erosion and they are only commercial because the chalcocite zone is comparatively near the surface.

The color of outcrops will vary with the nature of the enclosing wall rock. Veins in limestone are more highly colored than those in quartzite or the igneous rocks. Limestone often shows a spread enrichment at the surface, the iron waters replacing the wall-rock for considerable distances beyond the actual limits of the fracture. Hematite coloring is common in the lime sediments, whereas the quartzites may be superficially painted with copper silicates without much iron.

The yellowish-brown color of contact metamorphic

areas is quite characteristic with occasional blotches of copper paint. The outcrops generally weather in bold relief.

The amount of surface coloring increases in the desert areas, partly on account of the more rapid oxidation, and partly because of the high evaporative factor. Then, too, arid sections are seldom forested, so that the coloring of mineral deposits is more conspicuous. Little or no difficulty will be found in recognizing the outcrop of veins, but the disseminated deposits must be more carefully studied. As a little oil will spread out over a large surface of water, so a little copper will stain a large land surface. It is often deceiving. I am no longer attracted by a chain of blood-red hills; they suggest to me the presence of lean pyritic mineralization without enrichment. Red Mountain, near the Three R mine, at Patagonia, Arizona, is brilliantly colored by iron oxide. It can be seen for many miles. On going over the surface of this andesitic porphyry mass, dirty yellowish patches show melanterite stains, and a few inches below the surface the unaltered barren pyrite is found, peppered through the slightly altered rock. Oxidation is shallow but the surface discoloration is vivid. At the Piedras Verdes, a name wholly unsuitable, the same condition exists, although here, as I have already mentioned, there are local segregations of oxidized copper ore.

La Caridad, near Nacozari, presents a most brilliantly painted landscape. The country is extremely rugged, suggesting periodic but torrential rainfall. High on one resistant peak a small orebody of enargite, which, by the way, is extremely persistent even in the presence of strong oxidizing waters, was mined. The rest of the mountain chain is barren. I use this word in a commercial sense. In looking for disseminated copper ores, avoid the intense flush and seek the more neutral tints of creamy-yellow or buff-grey.

The 'porphyry coppers' owe their commercial value to the continued and advanced oxidation and concentration of the copper contents of large masses of low grade sulphides. Chalcocite is the resulting product, scattered throughout a highly altered rock-mass. Chalcocite does not contain iron, hence its oxidation leaves no red stain behind. Such staining as does occur is due to the oxidation of imperfectly replaced pyrite, and the more highly colored the surface of these deposits, the greater the possibility of early impoverishment. At Morenci, Metcalf, Santa Rita, in parts of the Inspiration and Ray districts, and at Bingham, the porphyry or monite is of a creamy yellow color, bleached at the top. It, of course, shows unmistakable evidence of great rock alteration. Local patches of green coloration indicate the greater thickness of the orebody, and incomplete oxidation of the

¹T. A. Rickard. Lectures on Economic Geology, University of California, February, 1916.

protruding knobs of chalcocite. As Ransome says, "the largest orebodies of Miami are not often found under those surface rocks that are most vividly colored by copper compounds or iron oxides."

At Ray and Miami, the ore is found in a sericitized schist. The surface is of a pale chocolate-brown color, in which the pearly sheen of the sericite plates is seen plainly. Frequently a film of copper silicate paints the cleaved surfaces. I would here point out that at Morenci and Bingham such surface evidence of copper as is presented is in the form of carbonates, both the hydrous and anhydrous, whereas, in the silicified sericitized schist, silicate paint predominates. There is marked kaolinization of the monzonitic porphyries, marked sericitization of the schists.

To confirm opinions formed from many years' study of copper deposits, I wrote to a number of engineers asking for an expression of their views. One of our leading copper specialists thus replies: "It is said that if you know a subject you should be able to speak and write about it. I fear, however, that when it comes to describing the characteristics of the outcrop of a so-called disseminated property, I will have to fail." Such a frank statement emphasizes the necessity for systematic study of this subject. I take this opportunity of inviting a liberal discussion of my tentatively expressed ideas. Constructive criticism is more helpful than casual comment.

J. Parke Channing writes me: "The outcrop at Miami was a massive rock, intensely silicified, stained red in patches by iron oxide, and showing only occasionally small green stains of copper. The marked thing about it, however, was the fact that the rock undoubtedly had been intensely altered and while the presence of a small amount of copper was interesting as showing that copper had been one of the primary constituents of the rock, still the fact that there was not very much copper indicated that most of it had been leached and presumably precipitated. The No. 1, or Captain shaft, showed very much more copper on the surface than did the No. 2, or Red Rock shaft, and, as it turned out, the best ore was under the Red Rock shaft. The No. 3, or Red Spring shaft, was sunk in an area where there was a great deal more iron; in fact, the rock was soft and contained large quantities of iron oxide. It turned out that the zone of enrichment there was not over 8 or 10 ft. thick, and I imagine that the primary rock consisted largely of pyrite containing a little copper."

Walter H. Wood says of Miami: "The schistose area of the Miami Copper Company is netted with contraction fractures and later fissuring due to metamorphic changes of volume, accompanying mineralization and alteration. The ore belt is marked by silicification and intense alteration of the schist, a change that fades out into natural gray schist a few hundred yards north of the Miami and Inspiration mines. The ore zone is oxidized and leached to an average depth of 210 ft., this part containing small seams and veinlets of oxidized ore. Below this leached belt a few feet of mixed ore is succeeded by the zone of disseminated glance, a rather soft, much altered rock speckled with tiny glance grains and films."²

Pope Yeatman describes the mineralized surface of the Chile Copper Co.'s property as being gentle hillslopes, in a rainless district, of equable climate the year round, but where dews are heavy. He attributes the crusts that form on the surface to the action of the dew in furnishing moisture for dissolving the soluble salts. The orebody lies in an intensely crushed area of granodiorite. The actual surface is leached, is of a dull-gray color, and much fractured. The ore is the brochantite of the oxidized zone, due to the oxidation of chalcocite. A fresh face in the shovel-pits is green, due to the presence of this mineral. Some sections are iron-stained, but here pyrite is more plentiful. The transition zone between the brochantite and chalcocite is quite wide, hence this deposit differs from those of the disseminated sulphide ores in the United States.³

In summing up an article on "Disseminated Replacement Copper Deposits," C. W. Botsford writes,⁴ "The necessary phenomena attendant on the formation of a disseminated copper-ore deposit of the replacement type are:

1. An intrusion of granitic to monzonitic rock of some size, carrying a considerable percentage of iron minerals.
2. After solidification a general fracturing, while still at high temperatures. This may affect neighboring rocks, which may subsequently be mineralized.
3. The mineralization of large volumes of rock by euphriferous pyrite with the necessary accompanying metamorphism resulting in a quartz-sericite rock with few remains of the iron minerals.
4. Uplift of mass and exposure to atmospheric conditions.
5. Large areas showing residues from leaching.
6. Arid to semi-arid conditions and a rather mature topography where the rate of erosion must be slower than the rate of oxidation.

With these conditions fulfilled, the existence of a disseminated orebody is probable."

J. M. Buntwell describes the mineralized monzonite mass at Bingham as follows:⁵ "The occurrence of disseminated copper ore in igneous rock in Bingham shows that this extensive mass of monzonite carries disseminated throughout its areal extent, so far as known, irregular grains of pyrite and chalcopyrite; that the known mineralized tract is characterized, not by a series or succession of normal fissures, but by multitudes of thin, unsystematized parting-planes; that the rock is exceedingly altered by bleaching and silicification, especially in and adjacent to zonal areas of strong shattering; that assays show copper to be lowest at the surface and in old workings; that in relatively firm unaltered rock the copper ore lies in flat scales and films on the silicified walls of cracks, while in areas of great shattering and alteration, it occurs abundantly both on quartz-coated cracks and disseminated in the silicified bleached walls. In brief, copper is disseminated at depth through-

out the porphyry and occurs most abundantly in areas of maximum crushing, silicification, and alteration. Such general features as this apparently indicate a relation between quality of ore and degree of opening, alteration, and silicification, and suggest that the metallic contents reached their present state through secondary agencies."

In the tenth annual report of the Utah Copper Com-

HEMATITE VEININGS IN ALASKITE. COLOSSUS VEIN, 3 R MINE, PALM ONIA, ARIZONA.

pany, D. C. Jackling states that the ore-area now proved is 226.3 acres, with an average thickness of 455 ft. There is 380,000,000 tons of ore developed, of which 270,000,000 tons is classed as fully exposed. The year's addition (1914) was 10,000,000 tons in excess of that mined. The average assay of fully developed ore is 1.57%. In calculating this average grade, 56,714 samples, representing 334,518 linear feet of development, were taken.

Rock alteration is another helpful factor in sizing up the possibilities of a district. Advanced alteration, decomposition, and disintegration are reflected in the topography and areas of gentle slopes, or rounded hills are more promising for large low-grade deposits than rugged country. Such a surface is also easier to mine by the modern methods devised for the extraction of large daily tonnage.

P. B. Scotland, mine manager for the Arizona Copper Co., writes me: "The productive copper veins of the Morenci-Metalf district mostly occur in the more silicious phase of the porphyry intrusion, and their outcrops are characterized by heavy copper staining, frequently constituting ore. They are generally fault-fissures of varying magnitude and show very prominent outcrops of fault-breccia. The Coronado vein is the most important deposit of this type in the district. Its outcrop shows highly silicified iron-stained fault-breccia with occasional patches of partly oxidized sulphide ore showing. As a rule there is from 200 to 300 ft. of leached vein-matter before the sulphide zone is reached.

The outcrops of oxidized ore are therefore very common that have resisted weathering.

"The outcrops of broad metal-bearing intrusions in this district generally show iron stained open spaces in the matrix and in the joint planes of the porphyry. The degree of iron-staining is not great; it is more favorable to find the iron-staining extensive in area rather than intense in degree. Heavy iron staining may indicate the surface oxidation of a very pyritic deposit or vein with only a shallow and unimportant zone of enrichment beneath. A brecciated and faulted condition of the quartz-porphyry is favorable. A quiescent state of cooling of the magma, indicated by decided joint planes is unfavorable. Surface copper stains if confined to the more silicious and resistant parts of the outcrop are promising indications but in outcrops in more basic porphyry, staining may be entirely absent. Fragments of quartzite and limestone, floated in the porphyry magma, will generally show strong metamorphism.

"Veinlets of secondary quartz are common in copper bearing intrusions, but not necessarily indicative of orebodies beneath.

"The ferro-magnesian or dark minerals are invariably bleached and destroyed in any porphyry intrusion in which mineralization and enrichment has occurred and the feldspar is always changed to sericite or kaolin. The porphyry has always a characteristic crisp and weathered texture that is indescribable. In any particular

HEMATITE OUTCROP, OLD DOMINION MINE, ARIZONA.

porphyry intrusion, the most favorable ore is found where doming of the superimposed sediments has occurred. In other words, porphyry sills are so far ore bearing. I have observed rocks at the base of porphyry stock showed all the favorable outcrops of ore while sills branching therefrom show a more magnesian or dark some (is quite uncertain)."

The outcrop may be enriched not only by increment of metal but by abstraction of other material. Limonite and secondary silica will remain, outlining the casts of eroded sulphides, and these cellular outcrops often contain the precious metals. The completeness of the process of leaching depends on the relative solubility of the rock-constituents and the presence of effective precipitants, which may arrest the migration and cause residual masses of oxidized ore.

Of the many phases of hydro-metamorphism that influence the outcrop, kaolinization is, I think, one of the most important. Kaolinization must not be confused with sericitization, the processes are totally dissimilar. Kaolin is formed by the action of sulphate waters on the alkaline feldspars and their products, whereas sericite denotes hydro-thermal metasomatic reactions. Kaolin may be, and often is, an after-product of sericite. If the rocks, generally acid intrusives, are abundantly kaolinized, it indicates the complete oxidation of original sulphides and suggests enrichment below. Kaolinization is accompanied by a decrease of volume, with increased porosity. It tends to destroy the original structure of the rocks; hence, if on close examination the outlines of the feldspars are sharp, it is reasonably certain that the alteration is superficial.

A letter received from W. H. Emmons says, in part: "The silicification and kaolinization, other than the presence of copper salts, should lead us to the discovery of the porphyry deposits. My detailed work on this subject was done at Cananea. There a distinct segregation of silica was noticeable above some of the altered ore-bearing porphyry."

Silicification of the surface is significant, particularly as found in shear-zones or brecciated areas. Arthur Notman, geologist to the Copper Queen Consolidated, writes me from Bisbee concerning the newly developed porphyry mine on Sacramento hill: "The mineralization of Sacramento hill is confined to certain well-defined areas of brecciation, which have their greatest development at the east and west ends and south of the main axis of the hill, toward the contact with the Paleozoic limestones. The mineralization, consisting of pyrite, chalcopyrite, and bornite, with secondary chalcopyrite and covellite and associated silica, has replaced both the cementing material, largely silica, and the fragments. The proportion of sulphides in the ore so far developed is rather high, as indicated by the fact that experimental concentration shows a ratio of only about four to one. The copper content is materially higher than in most disseminated ores. The large tonnage already developed, including all material above 1.6% copper, shows an average of about 3.5%. In the west end of the hill particularly, the change from the breccia ore to contact deposits in the limestone is very gradual. The boundary of the mineralized zone of the north, away from the limestone contact in the case of the west-end orebody, is marked by a very strong fracture-zone, of apparently pre-mineral origin. At the east end, there are no such clearly marked structures. At surface, these brecciated areas have been altered almost entirely to hematite, limonite,

and silica. Copper-staining is conspicuous by its absence, there being only one or two places that show any traces of the carbonates or silicate. This is true also of the leached zone below surface, which contains practically no oxidized copper, save here and there for a few feet above the zone of secondary sulphides. The depth of the leached zone varies from a minimum of 100 ft. to a maximum of 200 ft., with an average of about 160. Toward the bottom of the leached zone, kaolin and other aluminous compounds appear in rapidly increasing amounts, and continue through the enriched zone, gradually giving way to sericite and unaltered feldspars as the zone of primary mineralization is approached. In all cases, there is a leached zone above the enriched zone."

A silicified outcrop is a favorable sign when the silica is of a crypto-crystalline variety, formed either by magmatic waters, by the carbonatization of feldspar, or by the abstraction of alumina from kaolin. Such silica is frequently found with sulphide ores or in the oxidized zone near the surface. Silicious outcrops often give place to a softer leached zone a short distance below the surface, as at Cananea.

In my first report on the Ray Central mine, I said in part: "The mineralized portion of the Ray field is not characterized by marked topographic detail; the hills present a rolling surface with but few cragged outcrops. Particularly is this the case where diabase comes to the surface, which, on weathering, crumbles to a soft rich brown earth so that it forms gentle slopes and saddles in the landscape. The ore deposit is in a locally crushed quartz-mica-schist, highly altered and silicified. The schist is foliated and cut into angular fragments by an interlacing network of tiny quartz films and veinlets, and by joints stained by films of iron oxide and copper silicate. As a rule, the rock breaks into fragments, the planes of which are not those of foliation."

J. E. Spurr, in his exhaustive geological report on the property of the Ray Consolidated Copper Co., discussed in great detail all the factors that have determined the present orebody. He says: "The Ray orebody belongs to a class of disseminated deposits in schist and porphyry. It has been silicified by the primary mineralization, hence the exposed part west of the Ray fault, being relatively resistant, stands out as a ridge of hills. It is iron-stained from the alteration of the original pyrite. The area of the maximum primary mineralization generally corresponds with that of maximum secondary ore-formation. The main belt of primary mineralization was thoroughly shattered during the fault movements that succeeded the original ore deposition. It contained only a fraction of a per cent of copper, so was not commercially valuable. From it the present orebody, averaging 2 to 3% copper, has been concentrated by downward percolating surface-water, which permeated the shattered rock, oxidized the superficial portions, dissolved out the copper and carried it down to the ground-water level, where it was precipitated as the rich copper sulphide, chalcocite. The primary orebody was first exposed to surface-waters by early Tertiary erosion. Subsequently it was covered up by the various desert wash

OPEN-CUT, SHANNON COPPER CO.'S MINE, METCALF, ARIZONA. (OXIDIZED ORE IN CONTACT METAMORPHIC LIMESTONE.)

CAVING SURFACE OF DISSEMINATED 'PORPHYRY COPPER' DEPOSIT, RAY CON. CO. IN CO., RAY, ARIZONA

and volcanic deposits of the Tertiary, and during this period of burial there was probably no secondary concentration. With the removal of the Tertiary covering, the ore-belt was again exposed to the surface, and climatic conditions appear to have been favorable for secondary concentration throughout most of the Pleistocene."

"Certain conditions have affected the process of secondary concentration. The surface of the secondary ore follows in a general way the larger inclinations of the surface. In detail, however, the apexes of certain sharp ridges are marked by corresponding troughs in the ore. This is believed to be the result of scant rainfall and defective underground circulation. Certain relatively impervious rock-formations have operated to retard the downward passage of surface-waters, so concentrating and localizing the secondary ore-deposition. In the Ray, Parson, and neighboring claims, a relatively thin sheet of diabase has been an important factor of this sort. Where this diabase is fortuitously so placed that it coincides with the ground-water level, it has been very effective in diminishing the thickness and raising the grade of the secondary ore-zone.

"Porphyry dikes, especially when kaolinized, and fault-zones where marked by soft gouge, also constitute relatively impervious layers that have locally deflected the circulation, and affected the localization of secondary ore. The diabase was, at the time of the primary mineralization, highly pyritized, but very little silicified. The alteration that took place tended to make it a soft tough rock not easily permeable to ground-water, hence it commonly contains, even quite close to the surface, a little slightly altered pyrite, while the adjacent granite-porphyry has been entirely oxidized and the copper leached out. These sheets and dikes of diabase frequently check the downward flow of water and concentrate the circulation along their upper margins. Chemically, the diabase appears to have been an unusually active precipitant of secondary as well as primary ore, apparently distinctly more so than either the schist or the granite porphyry. This is probably on account of the large amount of iron contained in the diabase, which is believed to have precipitated the copper from solution. Along the upper contacts of the diabase, therefore, the grade of the ore tends to be unusually high; while beneath, it is often unusually low.

"Strong copper staining at the surface is considered an unfavorable indication and is a symptom that the downward migration of the secondary copper zone has not been able to keep pace with the down-cutting erosion, so that part of the copper in the rocks is being carried away by the surface drainage while another part tends to scatter, seeking lower levels. Throughout the productive area, there are very few copper signs on the surface to indicate the remarkable chalcocite zone beneath."

While discussing the Ray district, it will not be out of place to describe the oxidized indications of an orebody that has no surface expression. The Globe Isabella group of the Ray Central Company, at the time of my examination in 1909, had been systematically drilled by

churn-drills and fairly well developed by underground workings, and, as a result, the bond on the property was relinquished. When I was called in by the old Ray Central company, I made a careful geological survey of the property and prepared glass models so that I could visualize the trend of the diabase sills and the effect of the rock-structure. A churn-drill chart gave the record of a hole that passed through leached schist for nearly 400 ft., and entered, without warning, clean chalcocite ore running 5 or 6% copper, which slowly faded off into leaner material. It was a perfectly good hole with no caving, and no casing was required. The record was blue-penciled "Assays unreliable." From my geologic study and the models, I was convinced that there was a depressed area or basin in this section that offered possibilities of great local concentration that had been penetrated by this drill-hole. I carefully examined the workings on the 400-ft. level and noted in the white silicified schist appreciable quantities of native copper and cuprite. From the sections, I saw that the orebody dipped about 20° to the east, following a diabase sill, and about the same angle to the south. I knew of the Mineral Creek fault to the east and its possible effect. On the 300-ft. level, a drift 400 ft. north of the co-ordinate on which the drill-hole had been sunk, showed a plentiful development of chalcotrichite in a highly sericitized and silicified schist. The general trend of the orebody suggested that this development was in the oxidized shell and, assuming that it maintained its dip, it would pass below the 400-ft. level and correspond with the results obtained in the drill-hole. From these data I outlined the approximate shape and extent of the orebody; as was verified by a small amount of development work. When the property was absorbed by the Ray Consolidated, the engineers estimated the net value of this orebody, allowing for amortization and all contingencies, as being approximately 44 million dollars. It was the salvation of the Ray Central.

I have made excerpts from the extremely interesting paper of Ira B. Jarolemon descriptive of the Ajo district, Arizona. "The mineralized area of about 55 acres, proved to depths of 400 to 600 ft., is a coarse quartz-monzonite originally overlain by a rhyolite cap, subsequently removed by erosion. The mineral is primary chalcopyrite and bornite, with little or no chalcocite. The monzonite is thoroughly shattered and silicified, at times entirely replaced by secondary silica. Pyrite is conspicuously absent. Very thin films of chalcocite are sometimes found immediately below the water-level, which, in this case, has no relation to the surface contours, although the bottom of the belt of oxidation parallels the water-plane. The variations in the grade of ore are due to the intensity of the primary mineralization and not to the enriching after-effects of solution and precipitation. The surface alteration is entirely unlike other low-grade copper districts. The sulphide bodies are capped by a crushed silicified material stained with malachite, limonite, hematite, and a little chrysocolla. The rock is hard, although the feldspars are partly kaolinized, which are in places stained green by absorption of copper from descending waters. The hills are of

EAST END OF THE RIO TINTO WORKINGS.

SACRAMENTO HILL, BISBEE, ARIZONA, AN ORE-CLEARING PORPHYRY MASS - 1901 PHOTO BY U.S.G.P.

(After Ransome, U. S. G. S. Prof. 1907)

a deep red-brown color with splashes of copper paint in protected places. The oxidized zone is constant in value from top to bottom, and in actual copper-content assays the same as the sulphide ore below. Malachite forms 85% of the oxidized mineral. Here, then, is proof that there has been little or no migration of metal or descent of surface-waters much below the exposed surface.

"To the east of this proved orebody, the same monzonite is soft and kaolinized, yellow in color, due to limonite, with but slight copper staining. The section is low and rolling, contrasting strikingly with the bold brown and green outcrops of the silicified ore-zone. The mineralization is pyritic, of low copper tenor, and the outcrop has more limonite and alumina and less silica and copper than the commercial deposit. There is a narrow belt of enriched chalcocite ore below. The ground-water level is constant throughout the district. Post-mineral erosion has been more rapid than oxidation. In the oxidation of the silicious chalcopyritic orebody very little free acid was formed to kaolinize the feldspars. The waters were evidently carbonated and the copper solutions early arrested in their descent. This is largely due to the aridity of the district."

I may add that there are 12 million tons of oxidized ore averaging 1.54%, and 28 million tons of sulphide ore running 1.5% developed in this property.

At the Old Reliable mine near Copper Creek, Arizona, the outcrops are essentially blow-outs or chimneys of rough, craggy, light-colored rock rising several feet above the weathered surface of diorite. The ore is primary chalcopyrite in a gangue of quartz and sericite with accessory tourmaline. Cavities or vugs in the brecciated material are lined with stout quartz crystals. The orebodies are of the pneumatolytic type.

The mines of the Moctezuma Copper Co., at Naco, Arizona, show mixed limonitic and hematitic croppings cementing a friction-breccia of andesitic rock, which weather out as two bold pillars, hence the name Dos Pilares. The outcrops contain carbonates of copper, but not in profitable quantity. The ore below has not been greatly enriched by secondary processes.

At Cananea, in Sonora, Mexico, a district I have not visited for seven or eight years, I remember well noting the great difference in the appearance of the outcrops of the contact metamorphic limestone deposits and the mineralized porphyry areas. The former had conspicuous gossan outcrops, with much silicate of copper, while the latter were leached and indicated the enriched chalcocite below by the rusty surface and general silicification. I should point out that in nearly all the areas in which copper is mined from contact metamorphic deposits, by far the larger part of the total output comes from the enriched ore concentrated in the intrusive porphyritic rock. This is well worth noting. The garnetized areas will resist erosion and attract attention, they will also furnish desirable oxidized ore for the smelter, and they may be included in the indicators of enriched porphyry deposits.

F. L. Ransome ascribes the lack of enrichment at Yerrington, in Nevada, to the impenetrability of the

rock-mass, and to the fact that erosion has kept pace with oxidation.

The Chilean mines owe most of their prosperity to rich secondary ores developed in regions of low rainfall and slow erosion. In the desert areas, oxidation may reach a depth of 1000 ft. locally, and rich masses of chalcocite and oxidized ore are frequent. At Cerro de Pasco, which is situated on the Andean plateau of Peru, 14,000 ft. above sea-level, the oxidized zone, to a depth of 300 ft., carried exceedingly rich silver ore. Famatina, in the Argentine, is in a mountainous and dry region, where erosion is slow and the water-table deep. The gossan has been leached of copper, but carried gold and silver. A zone of oxidized copper ore succeeds, carrying up to 15% copper, with 66 oz. silver, and 1 oz. gold per ton, while most of the primary sulphide ore carries only 4% copper.

At the Three R mine, at Patagonia, Arizona, the country is rugged and there is little opportunity for much of the rain-water to seep into the rock mass, except in the major faults. One such fault, the Colossus, showed considerable fracturing of the alaskite on either side of the main break. Hematitic staining was the sole indicator of the remunerative orebody subsequently mined below. The friable hematite outcrop gave place suddenly to lenses of pure glance. Stopes were mined 20 ft. wide of solid glance in an aluminized alaskite gangue, in an orebody 300 ft. long and 400 ft. deep. The lenses were connected by highly altered rock in which blebs of glance were irregularly distributed. There were a number of parallel faults, but the Colossus was the only one that showed this shattered outcrop and incidentally was the only one that was ore-bearing.

J. E. Carne says of the copper deposits of New South Wales, Australia: "The surface staining is very delusive. The most favorable indications are cellular iron oxide and secondary quartz, but this is only presumptive evidence, and not an infallible guide." The Barra and Moonta, of South Australia, had nothing at surface to suggest the carbonates and chlorides that were mined at a depth of 180 ft. except a concentration of lead minerals and precious metals.

The outcrops of the Great Cobar lode, in New South Wales, form a low ridge in a monotonous level country of Silurian sandstone and slate. Mineralizing agencies have hardened the lode; the sandstone is silicified, and the slate ferruginous. Copper showed only in one place on the surface. At 150 ft. the ore is a mixture of carbonates and chalcocite, while the oxidized zone extends to 250 ft., below which primary sulphides, pyrrhotite and chalcopyrite, are mined.

In Shasta county, California, some of the orebodies do not come to the surface, others have comparatively small outcrops, others have outcrops disproportionately large compared with the small orebodies underneath. The exposed portions of the orebodies have been much altered producing a gossan of limonite, some magnetite, and other ferruginous oxides. Iron has been oxidized and rendered stable to atmospheric conditions. Some of the dissolved copper has escaped into the surrounding country-rock, but most has been concentrated below as

chalcocite, bornite, and chalcopyrite, which, on further reduction, has formed native copper, cuprite, and to some extent, the carbonates. Silver was similarly concentrated. The partly impregnated wall-rock has been sericitized and kaolinized, stained red by iron salts. This has led to confusion and misconception regarding the connection of outcrops with the larger orebodies. The orebodies are of deep-seated origin and have only been exposed by long continued erosion. The present topography is widely different from that at the time the ores were formed. The topographic conditions are no criteria as to the depth of ore.

I have already described the attractive outcrops of similar enriched pyritic masses at Rio Tinto.⁶

Descriptions of outcrops could be multiplied indefinitely until the copper mines of the world were exhausted. Every district, in fact, every mine, has peculiarities all its own; there are no two alike; even so, the more extensive our field of observation and the greater the number of deposits with which we are familiar, the better prepared we shall be to pass judgment. Our ability to observe correctly must be fundamentally sound and we must discriminate between that which is apparent and that which is inferential. Similar conditions will bring about similar results, but we must be sure that conditions are similar, or our anticipated results may never materialize.

In this series of articles I have endeavored to point out the sign-posts to be read in the examination of a copper prospect. In the light of our present knowledge of the subject, it is impossible to make positive statements. In conclusion I suggest that an engineer always look for signs of widespread mineralization. If the metallic vapors have been strong enough to form important orebodies, they will have effected rock-alteration over a large area. There may be but one local concentration, but iron-stained surfaces, pyritic mineralization, veinlets of ore, kaolinization, and other indicators will be found all around. Copper deposits are generous with their outcrops and invariably in districts of productive mines there is ample mineralized territory. The possible size of the orebodies can be determined by an accurate decipherment of the general, aerial, and structural geology, and the grade of ore will be indicated by the rock-alteration, color of outcrop, the climatic conditions, and extent of erosion.

Oxidation tends to obscure the primary mineral relationships and causes a segregation of newly formed minerals. The order of attack by oxidizing influences varies directly as the relative affinities of the several metals for oxygen and inversely as their affinity for sulphur.

It is important to find out the nature of the primary ore. Old workings or deep canyons may show this, and if lean sulphides appear near the surface, no matter how gorgeously colored the outcrop, it is well to consider seriously before recommending the expenditure of money. The nature and extent of leaching, if correctly

diagnosed, other factors being satisfied, will often decide for or against development.

Ransome, in his able paper presented to the Canadian Mining Institute in March, 1910, reviewed the criteria of downward sulphide enrichment.⁷ Summarizing his views, confirmed by my own observations in the field, it would seem that progressive impoverishment of similar sulphide deposits, as depth is attained, in any given district is indicative of secondary enrichment. The change in the zonal arrangement should show dependence upon recent topography. The presence of such minerals as chalcocite or covellite is almost indisputable evidence that the primary ores have been oxidized and concentrated.

The presence of kaolin or alunite at any horizon in a copper deposit must be secondary and is due to attack of sulphate waters on gangue-material. Alunite is quite extensively developed in the so-called porphyry coppers. The pseudomorphous replacement of one mineral by another is, *per se*, evidence of change, as is also the encrusting or veining of one mineral by another.

"Just as a pearl in the oyster is an abnormal segregation resulting in a beautiful gem, so the ore-shoot in the earth is an abnormal segregation resulting in precious metals; just as there are thousands of oysters that contain no pearls to one that does, so there are apparently thousands of favorable receptacles for ore-shoots that yet carry none; just as the pearl diver finds it remunerative to hunt for the oyster that may contain his prize, so the miner finds it remunerative to hunt for the spot that may contain his ore-shoot; and though the paths of both are strewn with disappointed hopes, yet, the possibility of realization leads them on."⁸

QUEBEC province, Canada, produced in 1915 increased amounts of asbestos, chromite, magnesite, and copper-pyrite. The output of asbestos was 114,115 tons of picked fibre, worth \$3,544,392, an average of about \$30 per ton for the various grades. This is an increase over the \$2,895,935 produced in 1914, a consequence of the greater amount shipped to the United States, which is manufacturing asbestos articles for South American and domestic consumption that were supplied formerly by Germany. The output of chromite in 1915 was 14,976 tons worth \$221,287, a value of \$15.70 per ton. More than half of this, 8473 tons, was shipped to the United States. For several years the production of chromite and magnesite in Quebec had been practically nil. The magnesite produced in 1915 was 16,285 tons worth \$137,304, a value of \$8.50 per ton. The output of copper-pyrite ore in 1915 was 112,769 tons worth \$1,029,605, or slightly over \$7 per ton. Much of this came from the Weedon mine north of Sherbrooke, and was shipped by rail to smelters in the United States for treatment. Asbestos from Arizona is competing with that from Quebec and in 1915 the Arizona product brought an average price of \$41 per ton.

The Business of Mining

By W. R. Ingalls

*I have called the subject of my address to you, 'The Business of Mining.' Here is my first exhibition of heresy. Some may think that in addressing a class of embryo mining engineers, I ought to talk about the 'profession of mining.' But no, that does not sound just right. I should say rather the profession of 'mining engineers.' We mining engineers are strongly given to talking about our profession, about its dignity, about its ethics, and so forth.

Now, during recent years I have been wondering more and more whether we are not rather highfalutin' in talking about ourselves as professional men, and if we are not really simply business men and are shutting our eyes to the fact. Of course, this idea does not apply to the mining and metallurgical engineer alone. It pertains to the civil engineer in general, using the term 'civil engineer' in contra-distinction to military engineer, which was its original meaning, long before it became substantially restricted to the railway-builders, bridge-builders, and their kindred. As between the civil engineer, in this broad sense, and the physician, surgeon, lawyer, and clergyman, there is surely a difference. The medical, legal, and theological men all have to comply with certain regulations, either prescribed or sanctioned by the State. If they misbehave, they are liable to lose their right to practice. There is neither such a requirement nor such a penalty in the case of the engineer. He practices of his own free will and he may misbehave grievously without losing the right to practice, although he may lose the esteem of his fellow-men. Furthermore, the medical, legal, and theological men have a certain standing in the eyes of the law. If they are the holders of professional confidences, they are supposed not only to preserve them, but also may not be required on the witness stand to disclose them. The engineer also is under this moral obligation, but he possesses no such legal inviolability. In this respect the journalist probably has more of a legally recognized character than the engineer.

Well, what is a professional man? What is a profession? Let us refer to Webster's dictionary:

"PROFESSION. That of which one professes knowledge; the occupation, if not purely commercial, mechanical, agricultural, or the like, to which one devotes one's self; a calling in which one professes to have acquired some special knowledge used by way either of instructing, guiding, or advising others or of serving them in some art; calling; vocation; employment; as, the profession of chemist. The three professions, or learned professions,

is a name often used for the professions of theology, law and medicine."

This is a definition that illuminates rather than defines. The engineer when engaged in a mechanical operation, and that is the largest part of his work, is inferentially excluded, but when he employs the special knowledge that he professes to have acquired either for instructing, guiding, or advising others, he may be considered a professional man. I might also do some quibbling with respect to the doctors and lawyers, some of whom are charged distinctly with practices of commercialism, and are criticized for not conforming to the principles of altruism that are supposed to govern professional practitioners. Well, let us engineers brush away all pretences. Let us admit that in the main we are engaged in mechanical occupations, the prime purpose of which is to produce. The engineer constructs things and operates them when constructed. He is engaged in a business and needs no code of ethics beyond those that prevail in all kinds of commercial life as a guide of correct conduct. The young man who leaves school and enters into life with any other idea than this is likely to do himself harm.

How often have we seen graduates of mining-schools lingering unsuccessfully in a vocation for which they were unfitted, sustained by a pride in what they call their profession, reluctant to confess that they had made a mistake in going into something for which they were not adapted. I recall a young man of this sort who was graduated from a distinguished mining school and promptly called himself a mining engineer. He was not an engineer then, nor at any subsequent time—he had not the kind of a mind that an engineer must have—but he stuck on, flitting from one petty job to another. I urged him to switch to something else, but my suggestions were not favorably viewed. On one occasion, however, he got so far as to inquire of me what I should advise him to take up.

"Well, Brown," I said, "you will probably be shocked. I feel certain that you were not cut out for an engineer. But I have a notion that you would be a first-rate salesman in some business associated with engineering."

Of course he went right up in the air. The possessor of an engineering sheepskin to be a salesman! Perish the thought! He left me to take the superintendency of a pecayune mine, having a good title, but a dubious stipend. In a few months he was out of a job again and trying to collect arrears of pay for his last one. Then for several years I saw nothing of him. I surmise that he just managed to exist on fitful occupations. But mind you, he was during all this time a mining engineer and a professional man.

*Annual Commencement Address, School of Mines, University of Missouri, May 26, 1916.

One day he was ushered into my office and greeted me effusively. He was arrayed with elegance and exhibited many evidences of prosperity. He informed me early in our conversation that he had quit engineering and had become a salesman; that he had lately closed a half-million dollar contract and was going to be the general sales-agent of his company. He was not even sheepish in his confession; also he had forgotten my own advice to him.

I knew another young man who threw up a good but subordinate position for which he was well fitted to go into the field as advisory engineer. I urged him not to do it, pointing out that he was unfitted for it, and also that the unattached engineer is likely to experience six lean years to every fat one; but unfortunately, he had a fat one, right in sight. After a while the lean ones came and things began to be harder and harder. He used to send me desperate appeals for help and advice. Finally he wrote me that he was quite unable to earn a living by his profession; that he was just managing to get along by selling soap; what should I advise him to do? I replied that if he had found he could not get a living by what he called his profession, but could get it by selling soap, the logic of the situation seemed to me to point to his continuing to sell soap. However, in the course of time, he fell into a more congenial but modest niche in engineering and then was well content to stay there.

My purpose in relating these anecdotes has been to point out to you young men that you should not be led astray by pride in a supposed profession, which really is not a profession so much as it is a business avocation; and, secondly, that you should not hesitate to abandon your now chosen work if you find later that you are unfitted for it and made a mistake in choosing it. We all make mistakes and shall continue to do so as long as we are human. The most that any of us can hope for is not to make the same mistake twice, but, alas! we do even that. It is no confession of incapacity for a young man to say five years after graduation that he made a mistake in studying mining; that he would better have been a farmer or a merchant. It would, however, be distinctly a confession of incapacity to stick to something to which you know yourself to be unfitted, or something that is uncongenial to you.

Now, I am not the materialist that perhaps my words have indicated. On the contrary I am an idealist. All my life I have been doing those things that I liked to do and have not thought enough about what they paid. We have several kinds of engineers. There is first of all the great body of men who operate our mines and metallurgical works. They are the subalterns, captains, and colonels of our army. Fewer in number are those who advise about the development of mines, build metallurgical works, devise new metallurgical processes. They are the staff-officers. Many of them are great scientists, whose work is often inadequately required. Finally there are the engineers in whom the business instinct is highly developed—men like Jackling, Hoover, Hammond, Bradley—who are our generals. I admire the engineers of each of these classes. Each in his own way, humble or

high, is doing necessary work and contributing to the wealth that the mining industry bestows upon the world.

However, in mining, as in everything else, the scarcity is in good officers, and the higher you go, the greater is the scarcity. Every man in the ranks, every one of you, like Napoleon's soldiers, carries a marshal's baton in his knapsack, meaning that the road of promotion is perfectly open. Whether you will travel that road rapidly or not depends upon yourself alone. Now, please note that among our engineering generals the predominant characteristic is their business instinct. Their engineering training has been relegated to the background. There have been and are many generals who have had no engineering training, or have acquired it incidentally, without going to school for it. Such a one was Marcus Daly, a very great general, and among the many stories of him I recall one that illustrates my idea. It is reported of him that he used to say:

"I listen to the reports of my engineers and then I lock myself in my room lest they influence my judgment."

This did not mean that he depreciated either his engineers or their advice, but simply that he had to consider other phases of the question than those of purely engineering character.

And similarly, John D. Ryan, another great general, lately said to me:

"If the Anaconda company should do all the good things its engineers recommended, it would never pay a dividend. They are good engineers, and most of the projects they urge are good, but if we carried out all of them our capital would be perpetually tied up."

Here we have one of the great functions of the business general, namely to control expenditures within the limits of what can be afforded, having in mind first of all the interests of the stockholders, the owners of the business.

I am disposed to think that it is exactly this sense of perspective that the technically trained engineer must seek, especially to obtain, if he hopes to rise high in rank and material success. We have all noticed cases where the engineer upon assuming the duties incident to general management, considered many of his new duties as less important, and more or less subordinate to those of engineering, and would still dwell upon the engineering functions of the business instead of developing the possibilities in his new and broader field of effort. The technically trained man too often overlooks the fact that a knowledge of the markets where the materials and supplies necessary to production may be secured; their purchase, transportation, and storage; the employment and application of labor, supplies, and power; the supervision, compensation, and organization of labor, and the proper balancing of the activities of each department to itself and its relations to the other departments, the adjusting of the business as a whole to the activities of the outside world; the proper planning and analyzing of the operations of the business, the knowledge of the markets in which the production must be sold, together with the

selling of the production; the raising of working capital, disbursements and investment of earnings; are all functions of the business of mining that are separate and distinct from that of engineering and are co-ordinate in importance. And finally, there is ever to be borne in mind the great key of the secret of success in business administration, namely the getting of other people to do things for you, whether they be people that are working for you, people with whom you come in contact as buyers and sellers, or people who can in any way assist you in getting things done. The man who possesses this art is often described as a 'good mixer.' Uncouth and imperfect as that term may be, it expresses nevertheless something of the quality that is important.

In the development and equipment stage of mining and metallurgy, good engineering is all important. With a badly developed mind and a poorly designed metallurgical plant, the best of administrators is bound to have a hard time. It was formerly the custom, in the days when our industry had not attained the organization of the present era, that the mining and metallurgical engineer was a jack of all trades. The same man might develop and equip the mine, design and build the smelting plant, and operate both of them. That day is long past. Not only do we now specialize between mining and metallurgical engineers, but also do we specialize among builders and operators. One kind of metallurgical engineer designs and builds the plant and turns it over to the other kind to operate. In the two branches of work, a different kind of talent is necessary.

But of course the operating men are the great majority of the technically trained engineers engaged in the mining industry. Among them there is no question that we need a greater increase in business efficiency, a greater direction of attention to mining as a business, rather than as an art and science. The great need among our great mining and metallurgical corporations, which have wonderful technical departments and magnificent mechanical equipment, is not so much for more technical and mechanical efficiency, as it is for more business efficiency, more intelligent purchasing, better organization, better recognition of the principles of economics. The genius who possesses those qualities shines the same in whatever he undertakes. The mining industry does not merely obtain its generals sometimes from other fields. Often it gives its own men to other work. Consider Hoover, a mining engineer relatively young in years, who has become one of the great figures of the world. We of the mining industry knew Hoover as a great administrator long before the world at large had heard of him. During the last two years we have seen him, who had been conducting brilliantly mining operations in all parts of the world, exercise the same talents in feeding and clothing a nation.

The story of how the Belgian Commission, under Hoover, supported a people requiring \$65,000,000 per annum in food supplies with but \$10,000,000 in foreign contributions, is one of the romances of business. The British press has consistently asserted that it is not the

generosity of Americans for which Belgium should be most grateful, but for the commission's organizing genius, which is to say Hoover's genius. The problem was huge. It was necessary to utilize the credit of a population deprived of all metallic and almost all paper currency; to do a systematic banking business across enemy lines. Hoover's commission had so to organize its charity that the destitute in Belgium should be aided by their own countrymen. Its direct efficiency is attested by the fact that by careful purchases, the chartering of ships, and the substitution of volunteer effort for middle-men it kept the price of bread in Belgium below that in London and yet made \$6,000,000 profit on its sales during the first year. This was business.

I have dwelled upon some of the matters that you have not learned about in your course in this excellent school. Nobody learns about them in any school. I aim to impress upon you that in leaving your Alma Mater, where you have gone through some hard training under the guidance of able teachers, you have nevertheless been doing nothing but preparatory work. You must realize that your education and training have just begun and if you are to develop in your chosen work, you must keep on studying as you have been doing, but if anything, harder. You are no longer going to come up for examinations at the end of semesters, at which you are striving for marks, but you are going to be examined just the same, by the men who are employing you and their examinations will be the real thing. They will test what you know and that will mean dollars and cents, reputation and even livelihood to you.

How then are you to fit yourself for these coming examinations? I cannot suggest to you any simple *vade mecum*, no pony, crib, or dope-book; not even any plain line of conduct, practice, or study. As well as I can generalize, the broad precept is self-cultivation. Pay attention to everything that you are doing, whether it be work or play. Perhaps the best rule I can give you is: Observe and think. I venture to say that it is precisely that rule that your teachers in this college have been trying to impress upon you. Without any doubt, they have aimed especially to train you to think about the problems in mining and metallurgy that you are going to run into. Probably they have also trained you somewhat in observation, but alas, the training of most of us in observation is defective. We have not the excuse of the blind man afflicted by nature. We possess the sense of vision; but we go around with our eyes open and see not. Sometimes we do not even see enough to take care of our persons, and allow ourselves to be run down by automobiles. One of the most exasperating things in our business is the difficulty of getting young men who will see. In the mine, in the mill, in the smeltery, they will overlook the clues to the riddles, simply for not having been trained adequately to observe and report.

Listen to the story of how Thomas F. Walsh laid the foundation for his great fortune. This was told by Mr. Walsh in an address to the graduating class of the Colorado School of Mines upon an occasion similar to this,

and was re-printed in the *Engineering and Mining Journal* under the sub-caption of "Use Your Own Eyes and Judgment." That is merely a different way of putting what I have already said to you, namely, "Observe and Think."

Along in the '80s, millions of dollars were expended in the development of silver-lead veins and the erection of mills in the Imogene basin, nine miles from Ouray, in the San Juan region of Colorado. The mines proved disappointing. In the course of time the mills and machinery were dismantled and sold. In 1896 when Walsh visited the region, it had been condemned as a failure and exhibited all the aspects of a "busted community."

The country was abandoned, save by one Andy Richardson, the original prospector. One day Walsh went with Richardson to examine a claim near the summit of the range. The trail ran along the slope, and high up the side of a steep mountain. About three-fourths of the way up Mr. Walsh noticed a slide of reddish pyritiferous porphyry, which attracted his attention as having indications of gold in or near it, and he took some samples of it. He asked Andy if gold had ever been found in the basin. Andy replied:

"No, Mr. Walsh, there is no gold in Imogene, except a little associated with silver or lead."

Mr. Walsh said:

"Andy, I believe there is gold in Imogene, and I am going to find it."

His samples of porphyry proved to assay \$2 per ton in gold, and that confirmed his suspicion.

Among the mining claims owned by Walsh at that time was one situated at about the same altitude about 300 ft. east from where he sampled the porphyry. He had never seen the workings of this claim, for a snow-slide that never melted covered the tunnel to a great depth. The idea occurred to him that a gold-bearing vein passed through or near the porphyry dike. Therefore he directed Andy to drive a tunnel through the snow and have samples for him on his return. Upon his return, Andy gave him two or three sacks of samples saying:

"These are what you asked me to get."

Something within Walsh, as he described it, said to him:

"Go and take your own samples. Remember, Andy has been in the basin for 18 years and has never found gold."

Arriving at the mouth of the tunnel, Walsh found a dump of very showy ore containing zinc, lead, and pyrite. Going inside and examining the vein, he found an 18-in. streak of the same kind of ore that was on the dump. Between it and the hanging wall there was three feet of modest-looking quartz. It had none of the shiny mineral in it, and looked so barren that the average miner would consider it no good but as Walsh examined it closely he saw little specks and threadlike circles of glistening black mineral all through it, which experience told him was gold in a telluride form. While he was sampling this grayish-looking quartz, Andy grew uneasy. Thinking that he did not see the metalliferous streak, he called

Walsh's attention to it, saying that it was the pay-streak. Walsh replied:

"Never mind, Andy; I always assay everything in the vein."

His samples from the common-looking rock ran as high as \$3000 per ton. Looking over the situation, he found that the men who had done the work, although they were no ordinary prospectors, had saved the showy low grade stuff and had thrown the modest but rich ore over the dump, from which Walsh afterward shipped it. This mine—the famous Camp Bird mine—produced millions. It was a strange coincidence that the bonanza part of the vein was immediately beneath the spot where Walsh picked up the piece of porphyry on the trail.

Cases of this kind in the history of mining in the United States may be cited in great numbers. This is why there arose in the minds of the administrators of mines during the last decade or two the advantage of having a corps of trained observers in the underground workings, men having nothing to do with execution of the mining work, which opened an entirely new field of employment to the young college graduate. The Anaconda company was the first to develop this system, as it has many others of great industrial importance. D. W. Brunton, who was then consulting engineer for the Anaconda company, remarked in a technical paper in 1906:

"In my judgment, every company operating large mines would find it advantageous to employ, as a separate official, a competent mining geologist, whose duty it should be to follow continuously all workings and surveys, and note with precision those indications which hard-worked superintendents, foremen and surveyors, however intelligent, might easily overlook or fail to record. The proper man for this most important work is a man who has nothing else to do, and will do this one thing with industry, enthusiasm, and technical knowledge."

Just the same thing may be said of mining operation. The efficiency engineer, with his time studies, is above everything else an observer. Of metallurgy, too, the same story may be told. What are our great steps in advance during the last 50 years? In copper, the principle of pyritic smelting, coal-dust firing of reverberatory furnaces, basic converting, and electrolytic refining. In lead, first of all, the knowledge of compounding proper slags, then the filtration of smoke, and finally the blast-roasting of sulphide ores. In gold and silver, cyanide lixiviation. In mechanical concentration, the flotation process. In no one of these cases was the progress the result of a lucky discovery. No one drew a grand prize in the lottery of success. Each one was the result of technical evolution. The germ of the idea dated back a half a century in some of the cases. Scores of investigators had played with it, some of them coming within sight of success. In most cases the thing needful was staring them in the face, but was overlooked through the human failing to observe accurately. When finally it was found everybody was amazed by the simplicity of it.

It is only in the metallurgy of fine that there have been

no major improvements that I think of, yet that does not disprove my point. The art of zinc smelting was transplanted from China to England. From England it was taken to Carinthia, Silesia, and Belgium. America got it from Europe. Both in Europe and America it remains today essentially as it was in China centuries ago and is there still. Our improvements have been in details, chiefly mechanical, the principle remaining the same. Yet it has been by observation that we have improved the art in its multiplicity of details and created a practice that China will some day copy from us, just as we first got it from China.

But it is not enough merely to observe. Observation is of no use without thought. Observation must also be accurate. Inaccurate observation and absence of thought may result in such erroneous deductions as happened from a freak of Jim Gillis of Jackass Hill in the gold diggings of California. Jim was Mark Twain's 'Truthful James.' In the early days the stage road passed Jim's house, or cabin I should say. The old miners used to make sour-dough bread, and Jim had some in a pan trying to make it rise, but it would not. So he said, "I'll make you rise, darn you." So he put the pan out under the oak that branched over the stage road, and put a stick of giant powder under it, and as a result the dough rose and hung all over the limbs of the tree. Just then the stage came along loaded with Eastern women and 'tenderfeet,' looking for curiosities in the gold-diggings. A lady asked Jim what kind of a tree it was. Jim, with a sober face, replied, "Madam, that is a bread tree." "Really, is that bread we see?" "Oh yes," said Jim, "you can take the dough in your hands and work it into bread." Whereupon she took some of it and believed, and told everywhere about Jim Gillis' bread tree of Jackass Hill.

Such imperfect observation and such errors in deduction have led to some very serious mistakes both in mining and metallurgy. Accurate observation and sound thinking have led to brilliant successes. The trouble with most of us is that we neither see nor think. Millions of men before Newton observed apples to drop, but so far as we know, nobody before him gave thought to what caused them to drop. I have no doubt that hundreds of mill-men 30 years ago, or more, observed greasy froths of mineral floating on their mill-water and thought nothing about it, except to pronounce it a nuisance. I happened to be connected with the introduction of the cyanide process in the United States 20 odd years ago. We tested in our laboratory all kinds of minerals and knew accurately respecting the solubility of silver minerals. In a refinery that we operated we produced silver bars from black precipitate coming from some place in Nevada where some one was cyaniding old mill-tailings. Yet none of us thought of the general applicability of the cyanide process to silver ores. That important industrial development came years later, although it was screaming for our attention. But our ears were plugged and our minds were saturated with ideas of gold.

Now it is for correct observation and sound thinking

that your college training has been preparing you. I think there is a certain mistaken tendency among engineers of middle age to depreciate the importance of technical training. You are probably conversant with a questionnaire recently addressed by Prof. Mann of the Carnegie Foundation to 1500 engineers, asking what to their minds are the basic qualities for engineers. The collated replies showed that 41 points out of 100 should be assigned to character, $17\frac{1}{2}$ to judgment, $14\frac{1}{2}$ to efficiency, 14 to understanding of men, and only 13 to technical ability. Dean Marston, of Iowa State College, applied these figures to six acquaintances with whose personal characteristics he was familiar, and found that the banker, the grocer, and the merchant rated higher as engineers than did three successful practitioners of engineering.

There is manifestly here a misconception. The engineers of mature years have seen technically trained men remaining in the background, while non-technically trained men, by virtue of their character, judgment, efficiency, and understanding of men, step in and take a large number of the important administrative positions. Take railroading, for example. It is rather a rarity to find a railway president who has risen through the engineering corps. And in mining and metallurgy we find a large proportion of our chiefs taken from some other line or some other industry. That 1300 out of 1500 engineers—87%—consider some one of the elements that go to make up character the fundamental necessity for engineering success does not mean that the average of these 1500 engineers would rate the elements of character as making up 87% of the necessary qualifications of an engineer. Not one of those engineers would think of taking a graduate of a business college as a technical assistant. Such a one would not even be able to understand the language. No, the meaning is rather, I think, that on top of technical training the elements of character are of supreme importance and that in course of time they outweigh everything else and are those things that make for success in any business man. The technical training is a ground work, and only a ground work. If we find fault with the product of our technical schools it is for their assumption, real or fancied, that technical training is the whole thing, that they are creating professional men, not merely business men.

Thus I come back to my theme—the business of mining. Mining is a business. It should be so regarded. You should consider yourselves as business men. You are not going to be any better or any worse than other business men. You are not going to have any professional dignity to uphold that the honest stockbroker or the conscientious manufacturer of woolen goods has not got to have in mind. Both of them may be just as honorable men in business as are miners and smelters. There is no greater fallacy than when it is told of the miner that he, like the farmer, is one of the producers of clean wealth for the reason that coming out of the ground it does not come out of anybody else, with the implication that other kinds of wealth are more or less tainted. The

value of minerals in the ground inherently is nil. One hundred million tons of gold ore in Antarctic lands might not be worth any more than sand in Florida. By the expenditure of work in overcoming the obstacles of nature, it might become worth a great deal. All wealth is the result of human labor, generally assisted by capital, which is the result of previous labor. The wealth accumulated by the Standard Oil Co. by economies in manufacturing and marketing is just as clean as the wealth that the miner produces out of the ground. The banker, the broker, or the merchant is just as necessary and just as honorable a man of business as is the producer, and men of business who talk in terms of profit are just as honorable as professional men who talk about fees and engineers who pride themselves upon not being concerned with commercial considerations.

The mistake that is most often made in business is to suppose that we grow rich by taking riches from other men, or that nations prosper by depriving other nations of their prosperity. That would be true if riches consisted only of money, and if there were just so much money and no more in the world. But that is not so. Nations grow rich, that is to say, get comfort, ease, and luxury, only when other nations are growing rich too, only because other nations are growing rich. And so it is with individuals.

Consider, therefore, that in going out into the world from this school you are going into business—the business of mining, which is a very interesting business. Consider that you are going into business to create wealth, for if you do not create wealth you will have a hard time of it and might as well not try it. At first you will probably have to make money for an employer and a portion of what you make for him will come back to you as wages or salary. The cycle may not be obvious. It may be delayed. But the principle exists and always will. You will see many things done in ways that by book they ought not to be. You will observe many examples of crude mining, of muscular metallurgy—less now than a quarter of a century ago. But if muscular metallurgy makes money and refined metallurgy does not, obviously muscular metallurgy is the thing to do, for otherwise there would be no bank account and on pay-day there would be gloom. Keep that principle in mind, but observe always and think whether by doing the right thing an improved metallurgy would not make *more* money. Look at things always from the standpoint of the business man and not from that of the pedant and doctrinaire. Rub against your fellowman. Build up your character. Don't be afraid to take chances and accept responsibilities. And when the battle is over, let your friends be proud to read an epitaph like this:

Here lies one who took his chances
In the busy world of men;
Battled luck and circumstances,
Fought and fell, and fought again;
Won sometimes—but did no crowing,
Lost sometimes—but didn't wail;
Took his beating—kept on going,
Never let his courage fail.

United States Mineral Production

The value of the mineral production of the United States in 1915, according to preliminary figures compiled by the U. S. Geological Survey, was approximately \$2,373,000,000, a gain of \$258,000,000, or more than 12%, over 1914. The value for 1915 has been exceeded but once—in 1913—when a total of \$2,432,000,000 was recorded.

The metallic products reached the greatest value ever recorded, having advanced from \$691,000,000 in 1914 to \$987,500,000 in 1915—a gain of nearly 43%. The metals contributing most largely to this increase, their combined gains being 91% of the total, are as follows: Pig iron, increase \$102,630,000, or 34%; copper, \$89,930,000, or 59%; and zinc, \$78,589,000, or 22 1/2%.

The value of the non-metallic products in 1915 has been exceeded in 1913 and 1914 only, showing in 1915 a decrease of less than 3% from the preceding year. The figures for 1914 and 1915 are \$1,423,000,000 and \$1,385,000,000, respectively. The final figures for the value of the non-metallic products in 1915 may be somewhat increased over the preliminary figures given.

The mining activities and output reported for the six months just ended show that 1916 promises to be a record-breaking year in the value of mineral products.

Coal Mining in 1915

The production of bituminous coal and anthracite in the United States in 1915 amounted to 531,619,487 short tons, valued at \$686,691,186, an increase, compared with 1914, of 18,094,010 tons, or 3.5%, in quantity, and of \$5,200,543, or 0.8% in value, according to C. E. Lesher, of the U. S. Geological Survey. Of this total output, 442,624,426 short tons, valued at \$502,037,688, was bituminous coal and lignite, and 88,995,061 tons, valued at \$184,653,498, was Pennsylvania anthracite. Pennsylvania, with an output of 157,955,137 tons of bituminous coal and 88,995,061 short tons of anthracite, ranks first among the coal-producing States. West Virginia, with 77,184,069 tons; Illinois, with 58,829,576 tons; Ohio, with 22,431,691 tons; and Kentucky, with 21,361,671 tons, follow in order of production. Thirty States and the Territory of Alaska contributed to the total, 8 which number 13 States and Alaska had increased production, and 17 had decreased production, compared with 1914. To produce this coal, 731,008 men were employed for an average of 209 days.

THE VALUE of the base metals recovered from scrap in the United States during 1915 was double the value recovered in 1914, being \$111,919,230 against \$57,039,706. This was due to the higher prices received for these metals, and the consequent stimulation in the gathering of junk.

Concrete Stringers for Inclined Shafts

At a recent meeting of the Chemical, Metallurgical and Mining Society of South Africa, the concrete shaft equipment at the Bantjes Consolidated mines was discussed by W. W. Lawrie and G. Jildick Smith. As is well known, longitudinal concrete stringers for inclined shafts are a substitute for timber sills. They have been used in North America, notably at the Lake Superior copper mines and the Sudbury nickel mines. At the Bantjes shaft on the Rand, the incline is 34°, the track gauge is 4 ft. 2 in., and the rails are 60 lb. per yard. The three interior stringers each carry two sets of rails and are 2 ft. 9 in. wide at the top, the angle of batter of the sides being 65°. The two outside stringers are 1½ ft. each. The thickness or height of stringers varies, of course, with the irregularities of the foot-wall, but is usually 1 ft. 9 in. The building of the stringers in the shaft is done from the bottom upwards. The holding-down bolts for fastening the rails to the stringers were placed 6 ft. apart at first, but later were spaced at 4 ft. One white man and nine natives can build an 18-ft. section of concrete in a shift, making the cost for labor 63c. per foot of stringer. Ten bags of cement are required per 18-ft. length of stringer, making 86c. per ft. for cement. The cost for labor and cement is, then, \$1.49 per foot of stringer or \$7 per foot of shaft. The equivalent cost of timber sills on the Rand, as exemplified at the Nourse mine, is about \$12 per foot. In other words, concrete stringers on the Rand are 43% cheaper than timber sills. This is due largely to the high cost of timber there, as the material of the timber stringers costs more than the labor for framing and placing them. On the concrete stringers, the rails rest on thin steel plates bedded in the concrete at 4-ft. intervals at the holding-down bolts. Strictly speaking, the rails only touch these bedding-plates, but in practice the space between the concrete and the chair of the rails soon becomes filled with fine dirt.

The conclusions reached were: that concrete stringers are preferable to timber stringers in incline shafts up to 45° provided there is no movement of the foot-wall of the shaft; skip derailments do much less damage with concrete than with timber; for shafts from 45 to 60°, concrete stringers could be held in position by pegging the foot-wall at intervals.

At the Creighton mine of the Canadian Copper Co. in the Sudbury district of Ontario, a shaft of 55° incline is fitted with concrete stringers. Skips of 10-ton capacity are used. It was not considered safe to place the rails directly upon the concrete stringers, so steel girders were set in the concrete at 7½ ft. intervals for sleepers. Rails of 85 lb. per yard, 3½-ft. gauge, were attached to them, a bit of belting being placed between the base of the rail and the top of the girder. The concrete stringers are 3½ ft. wide and run down the centre of each compartment. These data on the Creighton mine were fur-

nished in discussion of the above paper, by H. Foster Bain who was a visitor at the meeting of the South African society.

In the Lake Superior copper mines concrete stringers have given good satisfaction after several modifications were made from the original design. These modifications included: changing the design of holding-down bolts so that the head is exposed at the side rather than on top of the stringer; employing wooden plank laid longitudinally between the concrete base and the rail to reduce the 'hammering' and noise produced by the bare concrete, particularly in steep shafts of 70°. The jarring on bare concrete stringers made considerable breakage on the skip as well as wear of the bolts in the concrete. Wooden cross-pieces may be used as a cushion.

Early History of Spelter

Spelter was first made in England in the early part of the eighteenth century, but the industry was destroyed by the merchants and importers of Preston, who reduced the price from £260 to £48 per ton (56 to 11 cents per lb.) when their interests were threatened. William Champion was one of the first English manufacturers of spelter, previously imported from India. He had his works at Warnley, a freehold property bequeathed to him by his father. On February 21, 1750, Mr. Champion presented a petition to the House of Commons in which he stated: "That he had spent a great portion of his life traveling abroad, and on his return to England had found the supply of 'tontorage,' commonly called spelter, dependent on the East Indies. Ingrossers had raised the price in 1731 to £260 per ton, and he applied in 1731 for a patent for making 'tontorage' or spelter, and this had expired in 1750. He had erected large premises and made 200 tons, when the importers brought in a large supply, and lowered the price from £260 to £48 per ton, at a supposed profit of £22 to £25 per ton to the importers. Not being able to procure such prices for his spelter as would admit of profit, he was a great sufferer, and he therefore prayed for an extension of his patent." The petition was opposed by traders of Preston and was rejected. It appears that brother of the petitioner, John Champion, in early life went to Holland, there representing himself as a beggar, and got employed there as a laborer during which time he learned the secret to make brass and zinc. When he left he induced several workmen to return with him to England, and with them he set up the works for the production of metal at Warnley. —*Daily Metal Reporter*.

By-products from coke-oven operations in the United States during 1915 were valued at \$78,382,904. These included ammonia, benzol products, and gas—domestic and industrial.

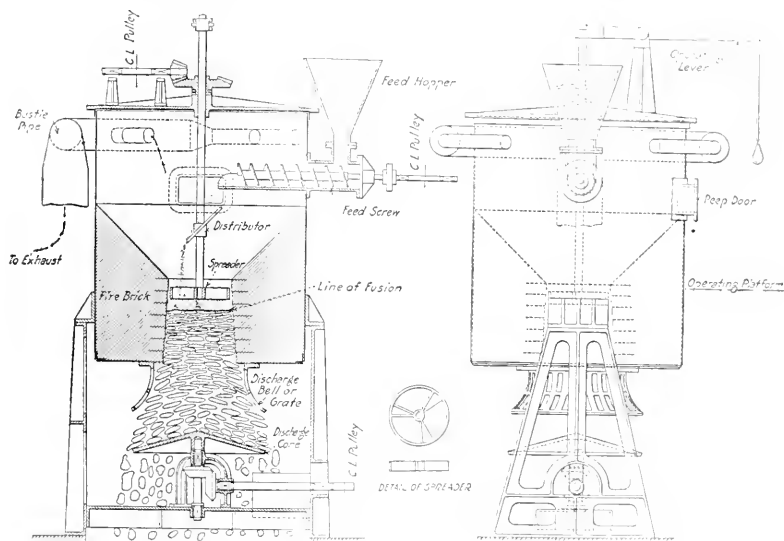

BRICK AND TILE manufactured in the United States during 1915 were worth \$125,794,844, a decrease of 3% compared with the output in 1914.

A Continuous Ore-Sintering Machine

*This machine was designed by P. O. Harding, now with the Braden Copper Co. in Chile, to treat iron ores, and is the result of a study to avoid the burning and clogging of the grate, so detrimental to sintering methods, and to overcome the operating difficulties and expense of igniting successive charges. Other features developed are the tapering tube and the protection of all parts subjected to heat.

From the illustration it will be noted that the machine is screw-fed. The mixture falls to the distributor, and is in turn further distributed by the spreader and

down rapidly, resulting in a burned grate. To effect a screening action of the air, preventing the fine ore from being drawn through the grate, finely-broken limestone is used. This readily dehydrates, as mentioned above, and powders; the grate in this way becomes clogged. In large sintering pans it is customary to 'dig out' the grates after each charge, and to place bricks or large chunks of sintered ore over the burned spots. This is continued until the grate is burned in a sufficient number of spots to cut the effective area to a point requiring replacement.

SECTION AND GENERAL VIEW OF THE HARDING CONTINUOUS ORE-SINTERING MACHINE

pusher. Air is drawn through the tube to the bustle-pipe by an exhauster. The clinkered material descends and is discharged by the extractor to the cars or storage-pit below.

The burning of grates in the down-draft machines is caused by the line-fusion progressing in waves. This may be caused by poor mixing or segregation afterward, and by uneven moisture-content of the mixture. When the peak of such a wave reaches the grate, the operator has his choice between a burned grate or dumping the charge before the mass is entirely sintered; he generally compromises. It is the common practice to protect the grate by a layer of limestone. Unfortunately this method acts as a barrier for only a short time. The heated gases from the combustion above dehydrates it, and where the hot masses of clinker come in contact insulation is broken

As to the ignition, this is continuous in this machine after the operation is once started. No oil is used and burner difficulties are obviated. The cost of oil and the expensive equipment of handling it are thus saved. The flaring-tube not only facilitates the downward passage of the clinkered material, but opens up channels for the passage of air. The clinkered ore is scoured of its dust, and small globules of unfused ore are thus swept back to the zone of fusion. This is important, since experience on unscreened sintered ore in one instance yielded 5% flue-dust at the blast furnaces, the untreated ore only 2.95%.

The pan equipment of the down draft process is subjected to wide variations of temperature. This is extreme, as the volatile content of the flue dust is carbon. This, together with the fact that one of the favorite methods of cleaning the grate is by violent hammering,

*Abstract from *The Iron Age*.

causes the pans to crack. This is applicable to the small pans. The grates of the larger units are 'dug out,' as mentioned, but contraction and expansion difficulties of the pans have been encountered that have not successfully been met.

In this machine the fire-body is enclosed by fire-brick. After the discharge-bell and cone reach their working temperature, this is maintained. They are circular, and therefore admit expansion with minimum internal stresses. The spreader is bathed in the green 'entering' mixture. If the line of fusion should become uneven and burning through the mixture necessary, the spreader can be raised. One feature not to be forgotten is the use of the spreader as a ram when the tube becomes skulled or the clinkered material arches.

The Future of Silver

Our esteemed contemporary *The Financial Times* (London) says:

A little over two months ago the continued rise in the price of silver, which had then reached 37d. per ounce, was threatening to raise serious complications, particularly for the Indian Government, which is pledged to maintain the fixed rate of exchange of Rs15 to the sovereign. By one of those queer turns of fortune's wheel, to which we are becoming accustomed in these disturbed times, the danger was averted just when it became most critical, and the Indian Government was not obliged to take any extraordinary measures to protect itself. The relief came, however, from a source which threatens further difficulty later on. Apart from minor factors, the main cause of the reaction, which has brought the price of the metal down to 30d., has been the selling of accumulated stocks in China, mainly owing to the political uncertainty in that chaotic Empire, and there is some reason to believe that the process has been carried so far as to endanger the currency system of the country. In spite of the high prices ruling there has been comparatively little increase in the production of the metal recently, except in the United States, and this has not in any way compensated for the shrinkage in the output from Mexico. Conditions in the latter country have gone from bad to worse and show no signs of improvement, and in any event it will be a very long time before confidence can be so restored that the output from the mines will be resumed on its former scale. In the meantime the employment of silver for currency purposes continues to increase owing to the withholding of gold from circulation, and the tendency is likely to continue for some time even after the War has ceased. It has even been suggested that after the War Germany and Austria may go upon a silver basis, and though we consider this extremely unlikely, the fact that the possibility is being discussed is in itself significant.

There does not seem therefore to be much likelihood either of a material increase in the output of the metal or of a shrinkage in the present abnormal demand, and

While thorough mixing of the ore and flue-dust is essential for the best operation of the machine, this need not be carried to an extreme, as is necessary with the down-draft equipment. However, a batch concrete-mixer is recommended. The flue-dust addition to the ore varies, but 20% of the 25% carbon-content dust has been found to give good sinter. The dust, however, can be increased, but care must be taken to keep the dilution to a point that excessive skulling does not occur. Sufficient water should be added in the mixing to make the ore take the shape of the hand when squeezed. The diameter of the tube should be 6 ft., height of column 3 ft., and estimated output 125 tons of sintered ore per day, these being the measurements that have been found to give best results.

there are obvious limits to the continuance of the drain upon the stocks of silver in China. As Samuel Montagu & Co. point out in their latest circular, the permanent currency requirements of China cannot be overlooked. At present they are in abeyance owing to the moratorium and the general unrest, and this has facilitated a steady secret flow of silver into the Treaty Ports. How much silver China has parted with during the last year and a-half can only be guessed at. Samuel Montagu & Co. put the shipments on Russian account during the eighteen months at 13,000,000 ounces and those to India and London at 20,000,000 ounces, making a total of 33,000,000 ounces. "No one," they go on to add, "at all conversant with the currency requirements of China can imagine that that country can dispense with so large an amount of its stock for any great length of time, for in normal times China attracts annually an amount of the world's supplies which compares appreciably with the total lately disgorged."

The conclusion is obvious that if and when confidence in the Chinese Government is restored she will become a heavy buyer instead of a seller. Even as it is, no further large quantities of the metal can be expected from that quarter, while there is no evidence of any real slackening off in the demand for coinage purposes. There seems, therefore, every prospect of the market remaining firm while the possibility of a fresh sharp advance taking place should there be any marked improvements in the internal conditions of China cannot be ignored.

THE VALUE of the materials that contain manganese depends largely on the percentage of metallic manganese, and also both on the manganese minerals present and the condition or state of aggregation of the material. This is for use in making ferro-manganese. The consumption of manganese in dry batteries is 20,000 tons annually. The value of an ore for this purpose depends on its manganese-oxide content. Caucasus ore contains up to 92% MnO_2 .

GOLD AND SILVER production of New Zealand in 1915 was valued at \$6,562,422, against \$7,799,291 in 1914.

Mining in Colorado

By George J. Bancroft

Throughout the summer months mining in Colorado has made steady advancement in spite of the fall in the price of the metals. In fact, one of the gratifying elements in recent mining progress is the total absence of a 'mining fever.' The mining that is being done nowadays in Colorado is done for the most part by mining people, not by 'tenderfeet,' and mining people base their plans on average metal prices, not on war-time quotations. For instance, the Vindicator people have gone into tungsten mining and milling in Boulder county.

As predicted some months ago, the quickly made money from the Boulder tungsten districts is supplying capital for neighboring counties. Gilpin has more men at work this summer than for several years and this condition exists in spite of the fact that a large part of her population is still busy digging tungsten in Boulder. That county, of course, is flourishing beyond belief. The slump in tungsten came just at the right time from a public standpoint. The sellers of stock were just beginning to get the "dear public" to buy tungsten shares when the slump came. I do not know that any of these shares sold were bad. In fact, such movements generally start with fairly conservative enterprise, but I think it much better for the mining industry and a whole lot better for the "dear public," if mining speculation is confined to those who understand the game.

Tungsten is still being bought and a good price is being paid for it, but what that price is, it is hard to determine. Unfortunately the tungsten market has degenerated to a horse-trading affair. In spite of this demoralized market, money is rolling into the tungsten fields by the cart-load and the accumulated capital is to a large extent being used in mining ventures of various sorts. As result Boulder, Gilpin, and Clear Creek counties are active along intelligent and conservative lines.

George H. Barnhart of Ouray is building a unique mill, for it is placed underground. The Mountain Top mine has some good ore but it is situated, as its name implies, on the very top of a precipitous peak in the San Juan. There was only one feasible outlet apparent to everybody and that was to connect with the long adit of the Atlas mine (above Ouray) and tram the ore out that way. Even then it meant building a long surface tram. Barnhart conceived the idea of building his mill underground, close to his orebodies. Thereby he obtains an equitable temperature and a closely concentrated operation. The light may not be very good on the day-shift, but at night it will be just as good as it would be outside. He is installing a crusher, ball-mill, two Wilfley tables and a flotation plant. The mill will be driven by electricity; it is about 12,500 ft. above sea-level, and will have an initial capacity of about 50 tons.

Altogether about thirty flotation plants have been installed in Colorado. Of these about one-half are successful. The failures of the other half might be more in-

structive than the successes if one could be sure they had any ore to work on. Two instances, which I went to some pains to investigate, turned out to be mills built for mines that needed an alchemist, not a common metal burglar.

Several interesting points are illustrated by the four big pumping projects now under way at Leadville. Within the last thirty years underground pumping has been done mostly with steam-actuated reciprocating pumps. Prior to that time there were a good many Cornish pumps in operation. Of the various types all have their advantages and disadvantages, but no one type has proved good enough to displace the others. Operations at Leadville have demonstrated a distinct and measurable advance in pumping and hence are worthy of special consideration.

The two pre-eminent steps are the use of centrifugal or turbine pumps, and the driving of the same by an extended vertical shaft. The rotary type of pump is far less heavy and cumbersome than the reciprocating type. It is, therefore, much easier handled in the shaft. The idea has prevailed that centrifugal pumps were limited to low heads, but this difficulty has been overcome by treating the water in several 'stages.' The discharge of one stage is the intake of the next, and in this way pumping-lifts of several hundred feet may be effected. I notice, however, that relay-pumps are still used in high lifts where centrifugals are employed. Of course, the cost of one high-pressure water-column and one high-pressure turbine may be greater than the cost of two low-pressure water-columns and two low-pressure turbines. Then again a mine does not always get all the water on the bottom level. It is often possible to halt the natural downward flow of water at some level that has a fairly good bottom, and connect it direct to an intermediate pump. These considerations, no doubt, had their bearing in designing the Leadville plants, for the greatest single lift is 425 feet.

The advantages of an extended vertical driving shaft are obvious to anyone who has worked with electricity in a wet mine. The farther the motor and wires can be kept from water and drip, the better the manager can sleep at night. The motor actuating the centrifugal pumps is 12 ft. above the intake. Supposing the pump is set 5 ft. above average water-level, that gives 17 ft. of fill before the pump is dead. The turbines have 200 ft. of vertical shaft. They call them 'shoe-string' pumps for this reason, but are thoroughly practical. I designed a pumping plant some years ago for a mine in New Mexico, in which the vertical revolving shaft extended clear to the surface. The relative cost of installing and operating an electrically-driven rotary pumping-plant in the Leadville district is said to be about one-half the cost of a steam-operated reciprocal pumping plant of the same capacity.

The four large pumping schemes at Leadville have been described in previous issues of the Press. The Down Town project and the Iron Hill are using centrifugal pumps. The Leadville Unit and the Wolfton are using 'shoe-string' pumps.

Concentrates

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

BARITE or barytes is barium sulphate; baryta is barium oxide.

THE TIMBER used in building the power-plant at the De Beers diamond mines in South Africa several years ago was brought from the Pacific Coast of North America, and cost \$1 per cu. ft. or \$85 per thousand board measure.

PLATINUM has declined from \$100 per oz. early in 1916 to \$64. Before the War it was \$42. Most of the platinum comes from Russia, where production fell from 300,000 oz. in 1912 to 124,000 oz. in 1915. Colombian mines in the period increased production from 12,000 to 19,000 ounces.

FUMES from blasting are generally worst when unexploded butts of dynamite are found in the broken rock. This shows that instead of detonating properly the powder merely burned. At such times unexploded sticks of dynamite may give trouble in the crushing of the ore on surface. These conditions may be corrected by using stronger detonators.

THE ACID used by the New Cornelia Copper Co. at Ajo for the leaching of oxidized copper ore will be furnished from the Calumet & Arizona smelter at Douglas, where it is a by-product of the reduction of sulphide copper ore. A large amount of lead was recently bought for lining the leaching-vats. Sulphuric acid of 9% strength will be used to leach the ore crushed to $\frac{1}{2}$ -in. particles.

ORDINARY SOCKS are not worn by German soldiers, it is stated. They use a square cloth somewhat larger than a large napkin, which can be wrapped around the foot in 30 different ways, according as it is desired to protect any particular portion blistered by long marches. This method of encasing the foot for the wear of heavy boots is well known to miners, many of whom prefer the square cloth to socks.

THE LONGEST horizontal diamond-drill hole that has been drilled on the American continent is believed to be 1870 ft. bored at the Quincy copper mine, Michigan, by the E. J. Longyear Co. of Minneapolis. The deepest core-drill hole in America is claimed by the Sullivan Machinery Co., which has drilled a hole 4900 ft. deep. Depths as great as 6900 ft. have been attained by drill-holes in South Africa.

WELL DESIGNED TRAM-CARS and good tracks are essential for an underground electric-haulage system. In a mine of the Moctezuma Copper Co., Mexico, a 3-ton locomotive could pull only five loaded cars, each of 20 cu. ft. capacity, when equipped with regular 'Anaconda' axles,

without the wheels slipping. But with cars equipped with roller-bearing axles, the same locomotive pulled six cars of 22 cu. ft. capacity each.

MAGNESITE BRICK of high quality was \$150 per 1000 prior to the War; now it is \$600 to \$650, for large lots. A recent export order for 20,000 at New York was quoted at \$775. Dead-burned magnesite is selling at \$80 per ton. All Austrian supplies are cut off. Considerable Grecian ore is coming to this country. In making magnesite brick the great problem is in burning. American ore is not the best for this purpose as it does not contain sufficient iron, a fault some makers are trying to remedy by adding rolling-mill scale.

IN WIRE-ROPE practice if it is desired to secure a sample from a coil of wire and not having a pair of cutters, the wire is bent backward and forward until it breaks at point of bending. It is surprising how few reverse bends are required to cause failure, and it should clearly demonstrate that if the wire in a rope is subject to similar reverse bends short life will result. The average user of wire rope is fully aware of this, and doubtless has secured samples in a similar manner; yet, how few stop to consider that if their sheave equipment is arranged to subject the rope to this reverse bending they cannot expect maximum rope service.

MOLYBDENUM is a white metal, malleable, ductile, and soft enough to be filed with ease. However, it is seldom produced in the pure state. Its melting-point is in question, although the U. S. Bureau of Standards places it at 2500° C. or 4500° F., which is 1400° C. above the melting-point of copper. Tungsten is one of the few metals that have a higher melting-point. The appearance of molybdenum varies with the method of making it; reduction of the oxide or sulphide by hydrogen, yields molybdenum as a grey powder, which, under heat and pressure, may be compacted into a brittle metallic bar. When drawn into wire, its tensile strength increases with the fineness of the wire. In other words, as with copper and tungsten, the more the metal is worked the stronger it becomes.

DROWNING a mine-fire in Michigan is being done in a thorough manner. The Dober mine, a large underground iron mine of the U. S. Steel Corporation at Iron River, has been burning for five years as a consequence of pyrite in the ore. Several months ago, the gas and fumes from the fire became so bad that nearly all work had to be stopped. An unsuccessful attempt to control the gas by a ventilating blower drove sulphur fumes among the residents around the mine. Now the management has decided to draw temporarily the pumps and machinery from the mine and divert Iron river, a good-sized stream, into the workings. Three days will be needed to fill the mine with water, and 2,000,000,000 gal. will be required. After the fire is extinguished, the mine will be unwatered and mining resumed.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

PLATTEVILLE, WISCONSIN

CONDITIONS IN THE ZINC-LEAD REGION DURING JULY.

The month of July in the zinc-lead mining districts of south-west Wisconsin will be recorded as one of the greatest periods in the history of the region. In shipments of zinc ore, especially with highly unsatisfactory market conditions, a high point was reached. Reserve stocks of zinc concentrate are large. Six new mines, developed within the past half-year and brought up to the producing stage by erection of elaborate equipments, commenced regular operations. Prospecting with drilling machines, the Keystone steamer type prevailing, reached a high point during the month, some operators being engaged with as many as 15 machines each. Rich strikes of zinc ore in virgin soil were numerous, and many areas mined successfully for years were checked up, bringing extensions into existence on adjoining lands which were promptly secured by mining lessees. Building operations continued at all points, 15 new plants being completed. Eighty fully-equipped mines contributed to the production during July, and 10 zinc-ore "refineries" operating at maximum capacity enabled the field to deliver to smelters direct over 12,000 tons of standard 60% commercial zinc concentrate. The zinc-ore refining branch of the industry will be materially enhanced in the near future by the construction of two, and perhaps three, new plants, one of which is to be the largest in this field. This plant is proposed for the Benton district by Indianapolis business interests now largely involved in mining in this field, the purpose being to include all low-grade zinc-ore producers. The new project is to be capitalized at \$500,000, stock to be taken by the companies becoming a factor in the undertaking, and to be paid for at the rate of \$1 per ton deducted from the sale of finished product. Small operators will be permitted to negotiate loans, enabling them to become active shareholders at a low rate of interest. It is proposed to employ the McDougal type of furnace with a total capacity of 200 tons of raw ore per 24 hours. The new plant will cost complete \$200,000.

Prices on zinc ore held nearly all month at \$60 to \$68 per ton, base of 60% zinc for top grades, while on seconds and medium-grade ore the base fell as low at one time as \$53 per ton, including down to 50% zinc-content. Some gain was made at the close of the month, inferior grades being brought up to \$58 per ton base, at which price shipping increased. All low-grade producers, and in this class were delegated all ores under 50%, suffered sharp discrimination in price, many being unable to market their output at all.

Lead ore was in poor demand all the month, and shipments were light. A fair gain was shown in production for the entire field; much of this class of ore being carried over. Prices were unsettled, offerings at the beginning of the month holding at about \$75 per ton, receding to \$70 per ton for 80% metal-content when the month closed.

Shippers of pyrite, and this includes nearly all zinc-ore refineries now in operation in the field, experienced another disastrous month. High prices prevailing for spot acid enhanced the demand for high-grade sulphur from the Louisiana deposits and high-grade pyrite. The average Wisconsin iron pyrite contains, on the general run of fine secured from separating-plants, less than 50 units, and with the exception of one or two shipments of note during the month nearly all the

current production and the reserve of the previous month was carried over. A careful tabulation of this class of ore held in the field at the close of the month was in excess of 6000 tons, and there was absolutely no sign that the situation would be in any manner relieved for a long time.

Producers of carbonate of zinc ore, buoyed up by a false hope early in the month that a buying season had set in, ac-

TOPOGRAPHIC MAP OF WISCONSIN ZINC REGION

celerated production, and a fair quantity was prepared for market. Such shipments as were reported came mainly from the mines of the New Jersey Zinc Co. in the northern centres. The price held strong at \$10 to \$50 per ton, 40% metal-content but sales were light, a little over 1,000,000 lb. A considerable reserve was piled-up and carried over.

Ore deliveries totaled 54,288,000 lb. of blende, 689,250 lb. of lead, and 4,533,500 lb. of pyrite.

LEADVILLE, COLORADO

PROSPECTS OF THE LACKAWANNA-HALFMOON DISTRICT AND THE HILL MINES.

It is no longer doubted that the Leadville district has an other rich and extensive gold-belt in the territory comprising the Lackawanna-Halfmoon section. The remarkable success of the Mt. Champion mine at the head of the Lackawanna gulch, together with the data gathered by geologists who have made a thorough study of the formations, mark this western corner of Lake county as one of the most promising mineral areas in the State. J. V. Howell, assistant professor of geology at the State University of Iowa is now in the Lackawanna territory completing work that he has been two years doing. He has covered Mt. Champion, the location of the Mt. Champion mine, Casco mountain, and Sunset mountain. He is now extending his work to Hunter's pass. Starbuck and Adair mountains, where several rich ore shoots have been discovered. Mr. Howell is greatly impressed with the possibilities of the ground, stating that the outcroppings of veins which are numerous, are richer and stronger in many cases than that of the Mt. Champion mine. The geological work in the Lackawanna

section is being done by the State of Colorado under the supervision of Russell D. George of the State University and head of the State Geological Survey. During the past month he spent several days in the territory looking over many points of interest, and noting the progress of the work under way. He endorsed Mr. Howell's impression of the area, and added that it is to be regretted that prospectors have turned their attention to other fields and neglected the Lackawanna-Halfmoon section with its promising indications. He also inspected the Mt. Champion mine, and considered it a wonderful gold producer with well-defined and extensive orebodies.

The Mt. Champion is the only large active property in Lackawanna, and at present is one of the richest producers of the Leadville district. The mine is near the head of Lackawanna gulch about 18 miles from Leadville, on the south-western slope of Champion mountain. A new 100-ton mill has been erected on Halfmoon gulch at the foot of the northern slope of the mountain, one mile from the mine. A tram conveys the ore from the mine to the mill. Last month the mine shipped approximately 300 tons of concentrate valued at \$100 per ton, and several bars of gold, making the total yield \$40,000. A large vein has been cut in the mine, and is being extracted through three adits. The work that has been done on the vein has opened the ore to a depth of 300 ft., and the deepest development shows the vein to be persistent. Fifty men are employed at the mine and mill.

Lessees have taken charge of the Lackawanna Belle property on Sunset mountain, and the latest report states that a vein of rich gold ore has been cut in the main adit, and is being followed with good results. This property has produced a large quantity of rich ore from workings on and below the adit-level. The vein was lost in the main adit, and water forced the abandonment below, resulting in closing the property. The uncovering of the vein again indicates the continuation of the rich ore-shoot ahead, and extensive development is contemplated. Should the ore prove up to expectations, another adit will be driven in to the vein from the bottom of the mountain, a piece of development that will give unlimited stoping ground and do away with water trouble. All the ore that has been taken from the Lady Belle netted over \$100 per ton.

Other discoveries of rich material have been made in the Lackawanna district, and before the winter suspends surface work many veins may be found. Prospectors recently located a vein on the south side of Lackawanna peak, where the outcrop showed a brown honeycomb quartz that assayed 53 oz. of gold per ton. The development of this vein is now being rushed by locators who have traced it for some distance.

Mining men must now begin to turn away from the old and developed centres and seek new fields for exploitation. Present operations, which continue development of the old mines, are at the high expense of draining and sinking, items that were inconsiderable in the early days when ore was found at the surface. The work now being done through the Penrose, Harvard, and Wolfstone, and that proposed for the Mikado, has been successful in removing the water from the greater portion of the district, but it has cost a large sum. The returns for this expenditure should be great and undoubtedly they will be, providing a high metal market prevails for several years. But it all goes to show that the new mines, the rich mines of the future, must be sought away from the present centre of activity. The Lackawanna-Halfmoon section is extensive and rich, and awaits the time when mining men will fully understand its value and turn their attention to its development. The only drawback to the section is its isolation from transportation, being 18 miles from the nearest railroad siding. Prospectors prefer to work nearer home, it seems, and for that reason more than any other the wealth of this ground has not been discovered.

The manager of the Leadville Unit (U. S. S. R. & E. Co.), H. S. Lee, operating the Harvard and surrounding properties

on Fryer hill, has a new problem to solve before the ground is drained. It appears that after the Harvard shaft was unwatered several weeks ago, water rushed in from supposed workings on the lower level and blocked plans for installing a station pumping-plant at the bottom of the shaft. This flow, instead of being a temporary flood, continues to run in, and its source was not known until recently when the manager, on an inspection tour, discovered an old raise near the western boundary of the mine, where a large water-course has broken through and was pouring into the lower workings. The water was at once known to be from the surface, and could come from only two sources; the stream running through Evans gulch or the reservoir in the gulch just above the Harvard. The reservoir, however, was there when the Harvard shaft was sunk and no water trouble was then experienced. So unless water-courses have gradually worked their way through the interlying formations, the water does not come from the reservoir. The stream is the only remaining factor and steps have been taken to prevent further trouble from that direction. A large flume is being built through $\frac{1}{2}$ mile of the gulch above the Harvard to carry off the water. Mr. Lee states that this work will cost \$2000, but it will effectively block any channels whereby the water has been running underground and in time will more than pay for itself. Aside from the draining, the operations of the Leadville Unit are progressing in a satisfactory manner. Large bodies of high-grade carbonate of zinc have been opened in the Tip Top shaft, and three shifts of miners are extracting ore. The property is now producing 50 tons per day, and the output will be increased from time to time.

Plans are complete for re-opening the old Fitz Hugh property, also controlled by the Leadville Unit, and rated as one of the big mines of the district, now that the water has been drained. Other extensive developments in this territory are proposed, and the coming month should see a heavy production from the mines.

The Wolfstone shaft of the Western Mining Co. is now drained to the 1000-ft. level, where the old steam pumping machinery is again at work, handling the flow from this point directly to the surface. The shaft is being re-timbered, which until recently was under water. Following the shaft work it is planned to drain the remaining 100 ft. to the bottom, and probably sink still deeper. The property continues to ship 350 tons of high-grade carbonate of zinc daily.

Discussing the low price of Alaska Gold shares—\$16—the *Boston News Bureau* considers that this is due to the low value of the ore treated. In the year ended December 31 last there was treated 1,115,294 tons of ore averaging \$1.15 per ton, with tailing losses of 21.9c. per ton. It so happened that for the eight months ended July, including December 1915, the tonnage treated and the average grade of ore were practically the same as for the period covered by the annual report. For the eight months referred to, ore treated was 1,176,097 tons of an average grade of \$1.17 per ton. If losses in tailing be estimated at 22c., the net recovery was 95c. This compares with \$1.50 net recovery estimated when the company was formed. In 1915 average mining, milling, smelting, and miscellaneous costs were 71c. per ton, not including all development. It is safe to say, however, that even as at present operated, Alaska Gold is earning its current expenses and interest on \$3,000,000 bonds, but probably not much more than this. Returns are as follows:

	Tons	Assay value
December 1915	114,183	\$1.36
January 1916	119,914	1.42
February	122,856	1.02
March	162,796	1.03
April	165,930	0.94
May	175,215	1.40
June	164,800	1.06
July	150,403	1.24

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled for the Mining and Scientific Press

ALASKA

The Alaskan mining industry in 1915 is detailed by Alfred H. Brooks and others in Bulletin 642-A of the U. S. Geological Survey. With a map the publication covers 71 pages. Twelve parties were engaged on surveys and investigations, the season varying from 3 to 8 months. Reconnaissance surveys covered 10,700, and detailed geologic survey 200 sq. miles. The areas included south-eastern Alaska, Copper River basin, Prince William sound, Cook Inlet-Susitna region, Yukon basin, Yukon-Kuskokwim region, and a general investigation. The

had been placed on other duty. The suspension of operations at the mills has caused even less disturbance than had been anticipated.

ARKANSAS

RUSH. It has recently been published by Thomas Shiras of the north Arkansas mining district that the producers of that region have thrown away into the tailing piles an average of 4% ore in the last 12 months. This is but one of the many mistakes due to lack of working knowledge which have led to many failures in the early history of the field. Some of the tailing-piles have been found to contain as high as 8%. In an interview with J. C. Shepherd, of Rush, who is the largest producer in the field, he states that a saving of all but slightly over 1% is possible. He has been experimenting for some time on this problem and at present is engaged in building a 200-ton tailing-plant, through which to treat his 25,000-ton dump, as well as all chats coming from his concentrating plant. Mill construction during the early days of the district was poor, as far as it pertained to high recoveries. Few mills had tables or even hand-jigs. Carbonate and silicate ores do not have as high a specific gravity as blende, and in some instances the lighter ores are so closely interwoven with lime that unless ground fine complete recovery is impossible. The mineral is lost in both the fine and the coarse tailing. A radical change in mills has been made during the past few months. Tables of the Wilfley type have been installed, also hand-jigs and additional rolls; the loss generally

MAP OF ALASKA.

appropriation was \$100,000. The mining industry of the Territory was more prosperous than in any previous year, the total mineral yield being \$32,854,229, against \$19,065,666. This great increase was due to \$12,286,195 from copper, and \$937,885 from gold. Considerable attention was given to antimony deposits. The Tolovana district attracted many men. Several pages are devoted to the coal situation, including leasing.

ANCHORAGE. Six miles north of the Gold Bullion mine, J. Garber has uncovered rich gold ore at the head of Paterson creek, in the Willow Creek district. He has been at Anchorage recording his claims.

JUNEAU. On August 1 the 240 and part of the 300 stamp-mills of the Treadwell company were stopped. This started rumors on Douglas Island that the mines were to suspend work for some time. The superintendent, P. R. Bradley, states that there is no foundation for the rumors. He stated further that the shutting-down of the 240-mill and half of the 300-mill had resulted in a process of re-adjustment of labor, rather than in the actual letting out of men; that many of the workmen from the mills had been placed in other departments of the mines, so that the actual number of laborers out of employment, as a result of the suspension of operations at the mills

hereafter will be small.

YELLEVILLE. According to J. H. Hand shipments from the north Arkansas zinc-lead field in July totaled 75 carloads. Many producers are holding their ore for better prices.

ARIZONA

BISBEE. A 5-compartment shaft is to be sunk 1800 ft. deep by the Calumet & Arizona company. The shaft will be concreted throughout. It will serve the Junction and Briggs workings, the former of which are 1800 ft. deep.

MIAMI. During July the Inspiration mine produced 485,000 tons of ore, in spite of day lost on July 4. A locomotive repair-shop is to be constructed on No. 6 level. Two more 10-ton H. K. Porter air-locomotives have been ordered.

RAY. The Ray Hercules shaft was down 338 ft. at the middle of July. The first level will be opened at 455 ft., the next at 1000 ft. or lower. Churn-drills are still at work. The daily output is one carload of 6% copper carbonate ore. The power-plant has been ordered. It will be at Kelvin, near the mill being designed, and includes three 1045-hp. oil engines driving three generators.

WENDEN. Globe people are developing the Wenden Copper

Co.'s property 8 miles north, and 3 miles from Cunningham pass. Prospects of the district are said to be favorable.

CALIFORNIA

COLFAX. The International Smelting & Refining Co. has acquired control of the Walker copper mine, at which a mill is being erected, for \$630,000. Considerable development is to be done under the terms, costing \$25,000. John F. Cowan of Salt Lake City is managing director of the Walker Copper Company.

COPPEROPOLIS. The Southern Pacific company is surveying a line from Milton to Copperopolis, a distance of 17 miles.

GRASS VALLEY. The Golden Center company is to add 20 stamps to its present equipment of 20. C. E. Brockington is superintendent.

The Orleans mine, adjoining the Empire, is being re-opened in charge of B. Crase.

HEROULT. The Noble Electric Steel Co. has three furnaces running, two making ferro-manganese and the other reducing nickel ore from the Grants Pass district of Oregon. There are 125 men employed.

LAWS. The Tip Top gold mine is to be re-opened by the Louisiana Consolidated Mining Co. The company has an option for \$35,000 on the adjoining property. The 10-stamp mill may be added to.

NEVADA CITY. With a capital of \$200,000, the St. Louis Consolidated Gold Mines Co. has been organized to operate in the Willow Valley district. J. T. Hennessey of Grass Valley is secretary.

PORTERVILLE. The district's shipments of magnesite in July were 175 carloads worth \$85,000.

COLORADO

SILVERTON. The July shipments from 31 producers in this district totaled 227 carloads, 118 more than a year ago.

TELLURIDE. The following reduced facsimile of a notice posted at San Miguel County mines is of interest to silver producers:

NOTICE

Effective June 1, 1916, and so long thereafter as the New York quotation for silver shall average by the month sixty-five (65) cents per ounce or more, the undersigned Companies will pay a bonus of thirty (30) cents per shift to every employee who works a full month; but failure to work a full month, if due to sickness, injury or other cause beyond the control of the employee, will not cause a forfeiture of this bonus.

A copy of this notice has been filed with the Industrial Commission, State of Colorado.

THE HUMBOLDT MINES COMPANY

By Bulkeley Wells, President

BOULDER. The Logan Mining & Milling Co. is to erect a 25-ton flotation plant during September. This mine, in charge of H. Lower, produces rich gold-silver ore.

IDAHO

OROGRADE. Washington people have financed the Orogrande Gold Mining Co., which has purchased the Butte-Orogrande property of 340 acres of lode and 145 acres of placer ground, with 200-ton mill, etc. A cyanide-plant is soon to be erected, the machinery is due to arrive soon. Hydro-electric power is available.

COEUR D'ALENE

MURRAY. The Golden Chest mine produces a gold-tungsten ore which is difficult to treat, but a process is to be tried, devised by the superintendent, R. T. Horn, and R. R. Goodrich of the School of Mines at Moscow. As much scheelite as possible is hand-sorted, the ore then being crushed by stamps, the gold amalgamated, and concentration done in Harz jigs, and on Wilfley and Johnson tables. To remove the manganese from the tungsten concentrate it is proposed to try magnetic separation.

NINE MILE. During the year ended June 30, 1916, the Consolidated Interstate-Callahan Mining Co.'s profit was \$3,100,491 against \$1,591,773 in 1914-15. Dividends were \$3,254,930 and \$697,597, respectively. The surplus is \$806,711, against \$1,094,862.

KANSAS

PITTSBURG. One block of furnaces has been closed by the Pittsburg Zinc Co., with more to follow if the spelter market does not improve, according to E. V. Lanyon.

MICHIGAN

THE COPPER COUNTRY

HOUGHTON. Three units of the Calumet & Hecla leaching plant at Lake Linden are in operation. Within three weeks the company's Dollar Bay smelter will have another furnace in blast, likewise at Hubbell, making five and three at each plant.

During the year ended June 30, 1916, the Wolverine Copper Mining Co. treated 388,898 tons of ore, yielding 6,541,492 lb. of refined copper, equal to 0.853% in the ore. This is less than in 1914-15, but the profit of \$735,218 was an increase of \$417,017. Dividends amounted to \$660,000, compared with \$350,600. The surplus is \$862,529.

MISSOURI

JOPLIN. The *News Herald* recently published the following interesting note: Several of the assayers in this district make a practice of saving the remnants of blende samples analyzed during the year. At the close of the year the lot is thoroughly mixed and carefully sampled, from which an average or composite assay for the year is made. Each assay thus represents several thousand lots of ore. In most cases each individual sample included in the composite represents a carload of concentrate. In 1915, a composite made up of 1806 lots was assayed by Evans W. Buskett, and found to contain 56.76% zinc and 2.36% iron. For the same year, W. George Waring analyzed a composite of 9240 samples and found it to contain 57.19% zinc, 2.40% iron and 0.985% lead. This average sample has been assayed by W. W. Petraeus and E. W. Buskett for the last 19 years, and in that time the amount of zinc has not varied more than 1%, the average being 57%. A similar table has been kept by C. V. Millar and W. G. Waring. Their assays, however, show variations between 55.30% zinc, in 1901, and 58.95% zinc, in 1905.

The ore market at Joplin is dull and weak, blende ranging from \$50 to \$70 per ton for 60% product. The week's output was 2737 tons of blende, 122 tons of calamine, and 797 tons of lead, averaging \$59, \$10, and \$66 per ton, respectively. The total value was \$281,796.

MONTANA

In Bulletin 641-C of the U. S. Geological Survey, Eugene Stebinger discusses the possibilities of oil and gas in north-central Montana. The facts observed seem to warrant the

MAP SHOWING AREA COVERED BY OIL INVESTIGATION.

statement that considerable gas territory, on a scale comparable with the Alberta, Canada, fields, may be found and also that the area shows some probability of yielding oil. A rational search for oil and gas in the State should begin with operations in the areas where the rocks are most strongly arched.

BUTTE. The July output of the Butte & Superior was 15,000,000 lb. of zinc in concentrate, recovered from 51,710 tons of ore. This is a slight falling-off when compared with June. The new main shaft is completed and timbered to 1500 ft. It will be sunk to 1900 ft. The Black Rock shaft was damaged last week by a cage dropping for some distance.

On August 4 a serious cave-in took place at 2000 ft. in the Tramway mine of the Anaconda company.

North of the shaft at 1600 ft. the Butte & London has cut mineralized quartz. The south cross-cut is soon expected to cut the vein opened at 1100 feet.

The Tropic mine of Anaconda yielded 250 tons of $4\frac{1}{2}\%$ ore daily during July.

On the 1500-ft. level of the East Butte property a body of good-grade ore is reported to have been discovered.

Re-timbering of the Tuolumne company's Main Range shaft will be completed this month. The Colusa-Leonard shaft is in good order, as far as unwatered.

The Butte-Duluth mine and plant has been leased, by Court sanction, for 5 years to Alfred Frank of Salt Lake City. The mine must be re-opened within 15 days. The plant is to be enlarged to 500 tons' capacity.

The July pay-roll of the district approximated \$2,250,000, of which the Anaconda paid \$1,166,730, Butte & Superior, \$275,000, and North Butte, \$130,000. The wage was \$4.25 per day.

NEVADA

GOLDFIELD. At the Florence mine there is a good quantity of ore available on the 650-ft. level. The enlarged flotation plant is in operation.

VIRGINIA CITY. During July the Union Con. produced 1865 tons of ore, returning \$37,298 net. The cash surplus is now \$104,214, more than the company has had in 40 years. The Union shaft has recently been sunk from the 2000 to the 2680-ft. point, where work is held until the hot water at the bottom can be diverted by means of work that will be done through the Sierra Nevada-Union east winze. There is a working-con-

nection on the 2500-ft. level, and stations have been opened at 2400 and 2600 ft., and there will soon be one at 2300 ft. Within a few months the company expects to begin unwatering from 2700 ft. where are the lowest pumps, to 2900 ft.

Recently it was decided to explore not only the east vein of the Mexican, but also to explore the main Comstock. It was a considerable undertaking at the time as there were many thousands of feet of drifts to open up, and this work had to be done under great difficulties as to ventilation, until air connections were made. Before long will be the opportunity to explore the formation in a number of places and then the real interest will begin. Except for the ore taken out of the Union and Sierra Nevada, and a little exploratory work done in the Ophir, everything else that has been done in the last couple of years has been practically all dead-work.

NEW MEXICO

(Special Correspondence.)—Machine-drills are now in use at the Pacific mine, operated by the Socorro company, and driving is being done on the 500-ft. level. All lumber for the terminal station of the aerial wire-rope tram at mill end is now on the ground, and the ore-bins and head-frame are nearing completion. Timber for construction at the Pacific end is being delivered. No definite date has been set for placing the tram in commission, but it is understood it will be in use in the early future.

Operations for second half of July on the Last Chance mine, conducted by Mogollon Mines Co., yielded 17 bars of gold and silver bullion and 4.2 tons of high-grade concentrate. Ore treated for the period was 2125 tons. The new shaft is now some distance below the 800-ft. level, and sinking continues at rate of 2 ft. per day. The counter-balanced, self-dumping skips recently installed have relieved the congested hoisting conditions.

No. 2 orebody in the Eberle mine of the Oaks Co. has been cut south from the main shaft, and has the appearance of producing a large tonnage.

This district is credited with a total production of \$15,000,000, and is yielding at the rate of \$1,500,000 gold and silver per annum. With the consummation of larger and more centralized operations now pending, decreased mining and reduction costs that will be effected by hydro-electric power installations and more direct shipping facilities, a large tonnage of lower-grade ores will become available, and insure a greatly increased annual output for a long period. The future of the region is considered to be extremely good.

Mogollon, August 8.

OREGON

TAKILMA. At the Queen of Bronze mine a gravity train is to be constructed to the bins on the new railway partly built from Grants Pass to Crescent. The Del Norte Clans Co. of Chicago is setting-up a diamond-drill near Preston Peaks. D. Van Austrand of Denver contemplates erecting a 7000 mill, embodying flotation.—Ore shipments from mines in the Illinois valley are increasing fast. Last week 10 carloads left Waters Creek, at the terminus of the new line. Half of this quantity was copper ore from the Queen of Bronze and Waldo mines, while the remainder was chromite ore. These ores went to Tacoma and New York, respectively. A large quantity of chromite ore is said to be available.

UTAH

TINIC. Owing to lower prices of metals and the 100-day embargo on ore, wages at Tinic have been reduced 25% per shift.

At the Standard mine, a fan capable of delivering 2500 cu. ft. of air per minute is to be installed. A larger compressor

is also to be put in. Development at 1600 ft. has been satisfactory.

BINGHAM. On August 29 the Ohio Copper Mining Co.'s property is to be sold at sheriff's sale.

MARYSVILLE. The Mineral Products Co.'s mill, six miles away, has been re-modeled in charge of the president, H. F. Chappell. The revolving-kiln used to lose a lot of dust, but a dust-chamber and flues reduced this. The 100-ton mill is yielding nearly twice as much potash as formerly. The mine contains a large quantity of alunite of high grade. Near-by the Florence Mining & Milling Co. is commencing to erect a 100-ton mill.

CANADA

BRITISH COLUMBIA

TRAIL. Ore received at the Consolidated Mining company's smelter during July totaled 40,268 tons, making 286,978 tons in 7 months. The Center Star at Rossland contributed 110,177 tons; Le Roi, Rossland, 81,123; Sullivan, East Kootenai, 42,370; Le Roi No. 2, 9680; San Poil, Republic, Washington, 7928; United Copper, Chewelah, Washington, 6131; and Standard, at Silverton, 4209 tons.

Owing to better settlement terms with the Kusa Spelter Co. of Oklahoma, zinc producers of this Province will benefit considerably. As an example, V. W. Newton of the company says that in the case of a 40% ore or concentrate, with spelter at 8c., the difference in favor of the mine-owner under the new basis of settlement will be \$3 per ton.

ONTARIO

COBALT. The Coniagas company is to install a 100-ton Callow flotation plant, which has been ordered.

On August 15 the Seneca Superior paid a part liquidating dividend of 20c. per share. The total for 1916 is \$470,000, and to date \$1,577,526.

Nipissing during July produced \$288,577, from 134 tons of high and 6655 tons of low-grade ores. Development on vein 490 at No. 5 level was good. Surface dumps are now providing 90 tons of ore daily.

PORCUPINE. The Dome in July produced 38,400 tons of \$5.25 ore.

MEXICO

Shipments of mineral products into the United States during July, through Agua Prieta and Naco, were valued at \$1,182,600 and \$1,934,460, respectively. The Moctezuma at Nacozeni sent 7641 tons of concentrate, Cananea 6,515,982 lb. of copper and concentrate, and El Tigre 906 lb. of gold-silver bullion.

HIDALGO

PACHUCA. The Santa Gertrudis company reports that in June 19,775 tons of ore yielded \$154,000, of which \$16,500 was profit. The directors report that the further disturbed conditions resulting from the political tension between the governments of the United States and Mexico have militated more than heretofore against the successful operations at the mine. It became necessary during June temporarily to withdraw the American management and staff, and to arrange for the continuance of operations under English and Mexican management. A policy of future operations was arranged which necessitated the treatment of lower-grade ore than that milled during the last few months. Other causes seriously affecting profits are shortage of timber, owing to disturbed railway communications, higher cost of labor, and increased taxation.

Two fellowships of metallurgical research have been established at the UNIVERSITY of IBAHO, Moscow, by contribution from the mining men of the State. Each fellowship carries \$500. The metallurgist at the University is Robert Rhea Goodrich.

Personal

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

COREY C. BRAYTON is in Montana.

E. R. RICHARDS is at Salt Lake City.

GEORGE A. LAIRD has arrived here from Sydney, Australia.

ARTHUR L. PEARSE has returned to New York from Tucson, Arizona.

K. FREITAG has opened offices in the Hobart building, San Francisco.

T. A. RICKARD sailed for Victoria, to visit British Columbia, on August 12.

CHARLES E. DUTTON of Goldfield, Nevada, has gone to New York and Boston.

O. B. PERRY passed through San Francisco on his way from New York to Dawson, Y. T.

H. C. DUDLEY, of Duluth, was in San Francisco on August 16, on his way to Lower California.

R. E. CRANSTON left San Francisco on August 11 on an extended trip through Nevada, Colorado, and Montana.

JOHN WELLINGTON FINCH of Denver has gone to China for a large exploration company. He will be gone about a year.

ARTHUR NOTMAN, geologist for the Copper Queen Consolidated, Arizona, has returned to Bisbee after a month's vacation in New York.

VAN H. MAXNING, of the U. S. Bureau of Mines, is visiting important mining centres of the West in connection with the proposed experiment stations.

HENRY M. HOWE, professor of ferrous metallurgy in Columbia University, has been appointed honorary vice-president of the Iron & Steel Institute of Great Britain.

WALDEMAR LINDGREN, professor of economic geology in the Massachusetts Institute of Technology, has received the honorary degree of Doctor of Science from Princeton University.

Among those who attended the 30th anniversary re-union of the Michigan College of Mines at Houghton last week were: **O. G. ENGELER** lately from Sardinia, **C. F. SCHABER** of Bessemer, Alabama, **ARTHUR RIGBY** of Mineville, N. Y., **ARTHUR HOULE** of Bisbee, **LEE E. IVES** of New York, **W. R. BAUDER** of Cleveland, **E. H. BRANG** of Sandow, **B. C. J. H. WINWOOD** of Salt Lake City, **GEORGE R. SHELTON** of Salt Lake City, **J. M. LONGYEAR, JR.** of Boston, **F. O. WILLIAMSON** of Chicago, **WALTER SEGSWORTH** of Toronto, and **JAMES A. BARR** of Mt. Pleasant, Tennessee.

Obituary

ROBERT SAFFORD TOWNE, well known from his connection with Mexican mines, died at the Engineers' Club, New York, on August 3, at the age of 58. He was connected with the Fresnillo, Mexican Lead, Montezuma Lead, Soubrette, Tezuatlan Copper, and the Metallurgical Engineering and Process companies.

ALVIN ROBERT KENNER was accidentally drowned on July 4 while bathing in a small lake in a public park near Nevada City, California, to which place he had recently gone to inspect the Big Murchie mine before it was to be taken over by the Rio Plata Mining Co. He graduated from the Colorado School of Mines in 1907, after a thorough training at the Armour Technical Institute of Chicago. At Chloride, Arizona, he will be remembered by the many friends that he made while superintendent of a mine at that place. During the early days of the first Villa revolution in Mexico he was superintendent of a large mine at Parral, where he stayed until the Mexicans destroyed the railroad over which the mine shipped its ore to the smelter and the property closed.

THE METAL MARKET

METAL PRICES

San Francisco, August 15.

Antimony, cents per pound.....	10
Electrolytic copper, cents per pound.....	28.75
Pig lead, cents per pound.....	6.25-7.25
Platinum: soft and hard metal, per ounce.....	\$60-65
Quicksilver: per flask of 75 lb.....	\$74
Spelter, cents per pound.....	11
Tin, cents per pound.....	41
Zinc-dust, cents per pound.....	20

ORE PRICES

San Francisco, August 15.

Antimony: 50% product, per unit (1% or 20 lb.)....	\$0.60
Chrome: 40% and over, f.o.b. cars California, per ton.....	13.00-16.00
Manganese: 50% product, f.o.b. cars California, ton.....	12.00-16.00
Magnesite: crude, per ton.....	7.00-9.00
Molybdenum: 50% and over, per pound.....	0.60-1.15
Tungsten: 60% WOs, per unit.....	20.00

New York, August 9.

Antimony: Small quantities have changed hands at \$1.10 to \$1.20 per unit.

Tungsten: The situation continues uncertain. High-class material is quoted at from \$25 to \$30 per unit. Export inquiry continues to be received by dealers, and a moderate amount of business is said to have resulted.

EASTERN METAL MARKET

(By wire from New York.)

August 14.—Domestic buying of copper is reported; there is better demand for lead; spelter is firmer with better demand.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, according to quantity. Prices, in dollars per flask of 75 pounds:

July yields were: Braden, 2,760,000 lb. (low, due to bad weather); Kennecott, 10,750,000 lb.; East Butte, 1,895,120 lb.; Old Dominion, 3,852,000 lb.; Miami, 4,310,000 lb.; and Greene Cananea, 4,600,000 pounds.

Discussing copper recently, Joseph Clendenin, sales manager for the A. S. & R. Co., stated that the market has been cleared

of metal as never before. The large producers are now at the remainder of the year, with no or large stock piling.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.	Average week ending

The inclination of prices has been upward, with periods of steadiness. The Indian Bazaars have been active, and the harvest promises to be good. China sold on recent rises. The advance in price of money in London has unsettled China exchange, and it is possible that this will adversely affect the silver market. Stocks in Shanghai on July 15 consisted of 30,500,000 oz. in silver and \$17,000,000 in other forms.

Exports of silver from San Francisco to the Orient on August 12 totaled \$700,000, say, 1,060,000 ounces.

Tin is strong at 39.25 to 39.75 cents.

Eastern Metal Market

New York, August 9.

Copper again presents the best tone of any of the metals. It is far from active, but the metal in second-hands is about cleared up, and the quotations for near-by deliveries are stronger.

Zinc is lower; the market is dull and the future is uncertain. The expected cut to 6c., New York, by the principal producer of lead, came to pass, but did not bring business.

Tin is in bad shape because of the excessive quantity of Banca tin on the market.

Antimony has continued to decline.

Aluminum continues firm at 58 to 60c. A decrease in imports has been a supporting factor.

The prices of many steel products have been advanced. The domestic demand is slow, but export requirements are greater than ever. Orders placed for shell-steel in the past few weeks aggregate nearly \$100,000,000, and more steel is wanted. The pig-iron market is dull and weak, likewise that for old material; which is a subject for discussion in view of the great production of finished products.

COPPER

As a result of the absorption of re-sale lots, near-by metal is scarce, and there is a tendency to ask premiums for spot delivery. The quotation for spot at this writing is about 26.50 to 26.75c. cash, New York. As a matter of fact there has been but little business in the past week, but the tone of the market is much better and prices are firm. Lake is about 26.75c. cash, New York, but nominal. October and November can be had around 25.50 to 26c., and December at 25c. There have been some export inquiries in the market, but reports differ as to whether business resulted. The trade is surprised, in view of the stiffening of the market, over the action of some of the larger rolling mills in reducing their quotation for sheet copper from 37½ to 35c. The smaller mills, while they will make the lower price to the regular customers, continue to ask 37½c. from newcomers. "Copper Gossip," published by the National Brass & Copper Tube Co., recently said the following: "The outlook for a heavy consumption of copper during the balance of the year is excellent. For a long time to come manufacturing activity is assured. Melting continues about as it has for some time, and this feature of the situation indicates an underlying soundness deserving particular consideration. The tremendous pressure put upon manufacturing capacity for many months has afforded an outlet for an enormous tonnage of copper. Unusual foreign orders kept domestic plants working night and day. Meanwhile local and domestic requirements have been held up to a large extent. But later on we look for a condition of remarkable prosperity resulting from a deluge of domestic orders. As regards copper, it is probable that with the establishment of a satisfactory price level new business in heavy volume will be attracted, especially as dilatory buyers appear to be waiting for some such action."

The London market for spot electrolytic was quoted yesterday at £124, against £125 a week previous. Exports from August 1 to 8 totaled 5966 tons. Imports (including ore, matte, and regulus) reduced to fine copper, in the first six months of the year reached the large total of 103,500 tons; total imports for the year 1915 were 127,500 tons.

ZINC

The market is lower, and the outlook is not good. Spot zinc was to be had yesterday at 8.50c., New York, and 8.25c., St. Louis. September delivery is quotable around 8c., St. Louis, and last quarter at 7.75c. The London market, at £41 for spot yesterday, is £11 lower than a week previous. Twice in the

week sizeable quantities of spelter have been sold "under the rule" on the floor of the New York Metal Exchange, which means that a few buyers have failed to take metal for which they contracted. On August 2, 75 tons of 'Granby selected' was sold for immediate shipment from the West at 8½c., St. Louis, a low price for that grade. Yesterday 50 tons of prime Western, en route from Illinois to this city, was sold on the Exchange for 8.15c. St. Louis, a price about 10 points below the market. Aside from these forced sales the market has been extremely dull. The preliminary figures on spelter production and consumption for the first six months of 1916, by C. E. Siebenthal of the U. S. Geological Survey, are variously construed. It is estimated by him that the production, etc., in that period totaled 330,922 tons, from which are taken foreign exports, 20,197 tons; domestic exports, 58,007 tons; and stocks of June 30, 24,000 tons; leaving 228,700 tons as the apparent consumption. It is pointed out that earlier in the year Mr. Siebenthal estimated the production for this year at 885,000 tons (based on available capacity), whereas the yearly rate indicated by his later figures for the first six months, is but 632,410 tons. This constitutes a bull argument. On the other hand, the figures just issued show that the stock on hand at January 1 totaled 14,253 tons, whereas on June 30 they had increased to 24,000 tons, the figures being subject to revision. In addition to the number of retorts on record June 30—193,696—there are now building or contemplated 22,188, all of which is not so favorable to the future of the metal. From August 1 to 8 exports totaled 1975 tons. Sheet zinc is unchanged at 15c. for carload lots, f.o.b. smelter, 8% off for cash.

LEAD

The expected reduction in price by the A. S. & R. Co. came late on Aug. 2, when it announced its quotations to be 6c., New York, and 5.92½c., St. Louis. Immediately after making the reduction the big producer booked two or three large export orders, but domestic consumers did not become active. Independent producers at once followed the reduction, but held at 6c., New York, for only a few hours, then dropping to 5.95c., which is about the quotation today. At St. Louis, 5.75c. can be done. It was expected that a good movement would follow the establishment of the 6c. level, but consumers continued to hold aloof from the market, evidently thinking they could buy more advantageously still. The result has been a quiet market. The London market yesterday stood at £28 15s. Exports in 8 days totaled 429 tons.

TIN

Through the week the market has been without activity worthy of note, and the one feature is the large stocks on hand, particularly of Banca tin, of which there is estimated to be 4000 tons. It sold yesterday at 36.25c., whereas spot Straits was quoted at 37.62½c. The offerings of Banca, at what is declared to be less than actual value, has upset the market. One steamer that arrived on August 4 from Batavia brought 1100 tons of Banca metal. Of Straits there is also an over-supply. A quiet market for some time to come is indicated, even though prices recede still further. Up to yesterday 1887 tons had arrived this month, and there was afloat 3285 tons.

ANTIMONY

The market has continued dull and adversely influenced by offerings of those who bought for profit, but see only losses in view. Asiatic grades were to be had easily yesterday at 11c., duty paid, and even at 10.50c., according to some reports. One or two fair-sized lots have been purchased, but in general the market presents a dead aspect. Needle antimony is nominally quoted at 8.50 cents.

EDITORIAL

T. A. RICKARD, Editor

SOURCES of flotation oils admittedly are comparatively few. We learn that the Canadian government is to investigate the possibility of utilizing pine-stumps in Northern Ontario for the manufacture of pine-oil. Flotation at Cobalt is increasing at a rapid rate, and the consumers desire to have a supply of oil near-by.

COPPER maintains a high price—27 cents. The other metals have gained strength during the week. So much copper is sold far ahead, with probable large sales in the near future, that its resistance to a decline is explainable. From the highest point during the current year to the present quotations, following are the per cent reductions in prices: aluminum, 8.9; copper, 13; lead, 29; quicksilver, 75; silver, 12; tin, 33; and zinc, 60.

SHAFT-SINKING records are always interesting. In our Butte letter this week we give some notes on Butte & Superior practice. By a combination of sinking and raising, a system increasing in popularity, an average of 250 feet per month was sunk in hard granite. The usual rate of direct sinking at Butte is 100 ft. monthly, timbering at the same time. At the Chief Consolidated mine at Tintic, Utah, a shaft 6 by 15 feet in the clear was sunk 256.3 feet in a month. For 150 feet the formation was hard porphyry, the remainder limestone. This is considered to be much above any previous record.

COAL is now being hauled from the Matanuska coal-fields to Anchorage, Alaska, over the new railroad, the first train moving on August 16. We are in complete agreement with the Secretary of the Interior when he says that "the opening of these fields is regarded as a most important valuable benefit to both Alaska and the Pacific north-west. It means cheaper fuel for that country, and it is confidently predicted that it will be followed by industrial and mining expansion." Probably in 1917 Fairbanks and other interior points will get this coal direct by rail, resulting in re-opening many promising lode mines that are now closed on account of high fuel costs.

POOR as Mexico is said to be, its trade with the United States alone for ten months of the fiscal year ended June 30, was \$119,080,000, of which \$79,023,000 was exported to this country and the remainder imported from us. This is a gain of 40% over Mexico's total trade of the previous year, which was \$88,288,000. In spite of chaotic conditions, justification remains for Humboldt's description "the treasure house of the world." Mexico

has nearly as large a population as that of Spain and almost four times its area. We note that some of the mining companies that withdrew their staffs when War with this country seemed imminent are now sending them back into Mexico, particularly in the districts distant from the northern border. Whether they are wise remains to be seen.

ARIZONA is to be host to the American Institute of Mining Engineers during the week beginning September 18. This is the first time that the Institute has met in that State. An appropriate arrangement has been made whereby smelting will be discussed at Douglas, mining and geology at Bisbee, and mining, smelting, leaching, and flotation at Globe. The papers to be read cover a diversified field. We have already abstracted some of them for this journal. Excursions will be made to the mines and reduction works of almost all the leading copper companies of Arizona, the Chino property in New Mexico, and the Roosevelt dam, the last mentioned supplying power to mines as well as irrigating the desert.

WE have received a letter from Henry R. Merton & Co., the metal merchants in London, announcing that "the shares in our company heretofore held by German firms have all been acquired by British subjects," and adding that the company's "articles of association now contain very stringent provisions by virtue of which the company is now and will always remain under exclusively British control." The objection we have expressed to the business connection between this firm, the Frankfurt Metallgesellschaft, the American Metal Company, and others, was based not upon the German control but on the fact that a small group of international or non-national brokers and dealers had the control of metal-selling in Europe and America. That objection remains.

BRITISH COLUMBIA can boast two big copper enterprises. The Britannia, on the coast, 25 miles north of Vancouver, is one of them. This mine has not yet got into full swing, and has had an undue share of bad luck recently. A disastrous snow slide in March 1915 stopped operations for three months, and a shortage of water for power during an equal period in the fall interfered seriously with production. Only 9,058,015 pounds of copper was produced in the twelve months of 1915, and on this a net profit of \$191,238 was made. The Granby Consolidated, in the Boundary district, is producing copper at the rate of 50,000,000 pounds per annum.

and in the nine months ending March 31, 1916, made a net profit of \$2,373,863. The Britannia is estimated to have 17,000,000 tons of 1.8% ore assured. The new milling units should treat 2500 tons per day, when operations are in full swing. The concentrate will be smelted by the American Smelting & Refining Co., at Tacoma, in accordance with a seven-year contract recently made.

ON another page we give abstracts of the quarterly reports issued by what are termed the "Hayden-Jackling porphyries"—the Chino, Nevada Consolidated, Ray, and Utah Copper companies. Their total yield was 109,241,946 pounds of copper; earnings, \$21,276,772; dividends, \$9,069,106; and surplus, \$12,157,664. In the previous period the figures were \$7,795,825 pounds, \$14,814,175, \$6,937,730, and \$7,650,588 respectively. These are big figures and highly satisfactory results. With copper at 27 cents and sales made far ahead, a continuance of this prosperity seems assured. Costs were reduced by all, the Nevada Consolidated showing a drop from 9.65 to 8.51 cents per pound. To treat approximately a million tons of oxidized and partly oxidized ore, a 1000-ton unit is to be erected by Chino. Additional fine-grinding machinery is to be installed at the old mill. A plant has been designed to treat several million tons of tailing. The only report giving the extraction is that of Utah Copper, which acknowledges 63.51%, a low point due to the effort to achieve a maximum production during the period of high prices for copper. We also give the Butte & Superior report.

COMPARISON is the essence of clear description; for instance, the practical value of a discussion on stoping systems depends upon the force of contrast. In this issue we publish an article elucidating the respective merits and demerits of various methods of stoping irregular masses of soft ore, as based upon experience in the Calumet & Arizona company's mines. The article is by Mr. Philip D. Wilson, assistant geologist to the company, but he gives full credit to Mr. M. W. Mitchell, a foreman in one of this group of mines, for the development of the particular methods now in use. These are various, for it has been found advisable to modify established practices so as to suit them to a diversity of local conditions. By the way, in the text as published by the American Institute we find the word 'matte' used in connection with timber and caving, to signify a protective covering; thus a "timber matte" is a covering of timber to protect broken ore from admixture with waste. Unless care is taken, this blundering use of 'matte,' noted by us in other publications, will become established. It should be 'mat,' of course. The incorrect spelling will make confusion with the metallurgical 'matte' that goes to a converter.

WYOMING is the only western state that is not important in metal mining. Comprising an area larger than Utah, and surrounded on every side by great mining regions, its mineral production is confined to oil

and coal, except for relatively small contributions of copper and gold, 175 tons of copper and 672 ounces of gold in 1915. A new industry is the mining of sulphur near Cody in the north-western part of State, not far from the Yellowstone National Park. The Midwest Sulphur Company is working open-cuts made by removing the shallow overburden of gypsum. The mixed rock underneath is said to average 35% sulphur in places where vents have allowed the sulphurous gas to escape. The rock is broken to 6-inch size, loaded in small perforated iron cars, three of which are placed in a closed retort, where steam melts the sulphur in four hours. The sulphur is drawn from the bottom of the retort, is cooled, ground, and packed in 100-lb. sacks. The refined sulphur is shipped to paper-mills, sugar-factories, druggists, and to ranchers that use it to spray crops or live-stock. The price is high at this time, being \$30 to \$35 per ton. Western sulphur has to compete with the product from Sicily, Japan, Louisiana, and Texas.

ARIZONA is the premier copper State, not only in yearly production but in number of large mines. We note that the tax commission of the State has raised the valuation of mines by \$54,705,910, of which \$19,000,000 is the increase on the Inspiration. The total valuation of Arizona's producing mines is given at \$172,731,913. The Copper Queen Company is assessed for \$36,159,300, the Inspiration for \$20,400,897, and the Ray Consolidated for \$15,568,782. The Calumet & Arizona company is assessed for \$25,248,003, which includes the New Cornelia mine at Ajo, and is second only to the Copper Queen, being more than double Miami's \$11,406,804. Among other well-known mines, the United Verde is assessed for \$20,687,011, the United Verde Extension for \$5,360,281, the Shattuck-Arizona for \$5,229,400, the Old Dominion for \$4,487,153, with the affiliated United Globe at \$4,353,936, the Arizona Copper for \$10,362,469, the Detroit for \$4,394,775, and the Shannon for \$1,020,797. In proportion to the amount of attention they have drawn, the gold mines of Mohave county seem small compared with the copper mines. The Tom Reed has the largest assessment, \$2,053,270, and the Gold Road \$318,998. The National Tungsten Co. in Pima county is assessed at \$278,500.

Mining Dividends

The prosperity of the mining industry is indicated by the large dividends paid during the first half of 1916. Contrary to what might be supposed, the Anaconda did not pay the greatest amount, but ranked below several others, including the Utah Copper. This company distributed \$8,934,695, while Anaconda paid \$6,993,750; this in spite of the fact that Anaconda is producing copper from its Butte mines at the rate of 165,000 tons per year as compared with the 100,000 tons of the Utah mine. Incidentally, Anaconda's July dividend has been postponed to August. The first place as a dividend-payer is held by a zinc-producer, the New Jersey

Zinc Company, which paid the tremendous total of \$18,200,000. Another notable zinc mine, the Butte & Superior, paid \$5,862,993 in the six months. Phelps-Dodge & Co., which is a holding company, paid \$5,400,000. Kennecott, another holding company, paid \$7,000,000; and the Guggenheim Exploration paid \$10,713,456. In Michigan, the Champion mine on the South Range exceeded the Calumet & Hecla, paying \$3,720,000 to the latter's \$3,000,000. Among other noteworthy copper-mining companies, the Calumet & Arizona paid \$2,565,676; the Miami paid \$2,054,563; the Nevada Consolidated \$2,500,000; the United Verde \$1,395,000. Among precious-metal mines, the Hollinger at Porcupine paid \$720,000 and the Dome \$400,000. The Homestake paid \$979,524; Kerr Lake, \$300,000; Nipissing, \$600,000; the North Star, \$100,000; Santa Gertrudis, a Mexican mine paid \$364,500; Seneca Superior, which has completed its career, paid \$335,219; Tonopah Belmont, \$562,500; Tonopah Mining Company, \$300,000; Tough Oakes, \$132,875; Yukon Gold, \$525,000. In the Coeur d'Alene, the Hercules Mining Company surpassed the Bunker Hill & Sullivan, paying \$1,450,000, which exceeds its issued capital, to \$827,500 of the Bunker Hill company, while the Interstate-Callahan, a zinc mine in the same region, paid \$1,394,970. A Californian quicksilver operator, the New Idria, paid \$200,000, which is 40% on its issued capital of \$500,000. The International Nickel Corporation had a prosperous half-year, paying \$5,705,876. Among the less fortunate companies is Goldfield Consolidated, which paid \$300,000 in 1915 but is temporarily off the list. So also the Tennessee Copper Company passed its regular July dividend, as did also Utah Consolidated. The Engels Copper Company, on the other hand, paid an initial dividend of $1\frac{1}{2}$ cents. All told, 1915 will be much surpassed by 1916, as the dividends for the first six months already exceed those for the entire previous year.

Labor Unrest

Labor troubles are more acute this season than usual. Great uneasiness is felt throughout the United States at the deadlock now existing between the railroads and four sections of their employees. The trainbands are demanding an eight-hour day with certain excess pay for overtime. These demands, according to the managements, are practically impossible to grant, but they have offered arbitration, which the employees have declined. The President has taken a hand in the fray and has called a series of conferences at Washington between the parties involved. At present writing practically nothing has been accomplished, both sides apparently remaining firm in their original positions. In case of a strike, the onus will be clearly upon the train-men, who, by reason of their refusal to arbitrate their differences, are arrogating to themselves an arbitrary power that will bring down upon them the full weight of popular condemnation. While it is undoubtedly true that, during the present high tide of industrial

prosperity, the railroad net earnings have been large, the lean years that have gone before should not be forgotten, nor should a possibility of further lean years be overlooked. It is to be hoped that a reasonable middle ground will be found, whereby some profit-sharing plan will be developed and this constant agitation be avoided. Copper-mining companies employ a wage-scale that fluctuates with the price of copper. Why not apply this principle to railroad operation, adopting a minimum as a basis, and a bonus depending upon the net earnings? The tie-up of the transportation facilities of this country would paralyze all industries. We hope that the President will justify his tenure of the highest office by averting so great a disaster. Mining would be greatly affected by an interruption to traffic, as this industry supplies 55% of the total of over a billion tons of freight hauled annually, and contributes 37% of the railroads' earnings. We note in a recent report of the American Railway Association that the net surplus of freight-cars on August 1 was 10,616, compared with 264,243 a year ago, showing greatly improved business of the railroads of the country.

The Treadwell Consolidation

On another page we publish an abstract from the report, just completed, on the consolidation of the three companies operating on Douglas island, Alaska. We have reproduced the larger part of the report because we know that it will be found interesting on account of its subject and the reputation of the engineers by whom it is signed. Indeed, the shareholders are to be congratulated in obtaining such good advice. Mr. H. C. Perkins, as an associate of Hamilton Smith, visited the Treadwell mine in 1889 and since then has had a world-wide experience. Mr. Hennen Jennings had been engineer to the largest gold-mining operations in the world, on the Rand, and, like his senior colleague, has won a reputation for sincerity and sagacity that is unequalled. Mr. F. W. Bradley has been 16 years in the service of the three Treadwell companies as engineer and managing director, although his official title is president; he has also been in charge of other big mines in the West and is regarded as a man whose ability matches his probity. Therefore the report is a valuable document. It deals with a serious problem; nothing less than the choice between abandoning vertical development or spending further capital in deeper exploration. The Treadwell mines have been doing poorly during the last three years, particularly the parent property. While so many million tons of ore have been blocked-out, the bottom levels are so poor that the proportion sent from the lower workings since 1912 has ranged only $1\frac{1}{2}$ % of the total mill-supply. It will be noted that the Mexican and Alaska United companies have been operated at a loss during the first five months of the current year, and we understand that 390 stamps, out of 960 on the three properties, had stopped dropping on August 1. The yield of the parent mine has declined from \$2.60 in 1914

to \$1.66 in 1916. Meanwhile the cost has risen from \$1.08 to \$1.32 per ton. Moreover the caved condition of portions of this group of mines threatens the loss of a considerable part of the ore reserves. It will be noticed that while the total of ore blocked-out is placed at over 15,000,000 tons, only 7,000,000 is considered by Mr. R. G. Wayland, the general superintendent, as reasonably sure of salvage. A big crack has been made through the main ore-bearing ground, endangering the availability of large blocks and compelling great care in the further extraction of ore. Therefore the committee of appraisal faced the most serious problem that confronts the engineer of mines: to go deeper or to quit. The reply to the question has been answered firmly and we believe sagaciously. The history of this group of mines, and the splendid production made by them, forbids a hasty abandonment of hope; on the contrary, the facts "make it imperative that all these mines should be explored and proved most exhaustively in depth," so says the report. But, in order to do this economically it is necessary that the three companies be consolidated, join forces, and unite in a comprehensive scheme of exploration, the result of which will accrue to the benefit of the consolidated property.

A Glimpse of South Africa

It is a great pleasure to us to publish, as it will be to our subscribers to read, the article on South Africa by Mr. H. Foster Bain, who is now editor of *The Mining Magazine* in London. Mr. Bain has just returned from a comprehensive journey of observation in South Africa, his travels having included not only the Cape Colony and the Transvaal, but also Rhodesia and the adjacent part of the Congo territory. Writing as an American, and transmitting to us the impressions formed during his first acquaintance with regions peculiarly interesting to mining men, he dwells chiefly on the human side of the mining industry. In the easy and agreeable style familiar to our readers he gives them vivid glimpses of the contact between the white man and the dark races of the interior, of the impact between our complex civilization and the simple ways of living characteristic of the indigenous population. But before he warns to his subject, we are given some necessary information concerning the political geography of what was formerly the Dark Continent of the days when Livingstone and Stanley stalked across our school-boy maps and blazed the trail of later knowledge. What most of us do not know about Africa is well worth knowing, and we venture to digress a moment to say that the War has exposed vast lacunae of misinformation in regard to continental areas even nearer home than Africa. Our State universities would further the education of youth—and even of our adult population—by establishing chairs of political geography, so that the average man might acquire an intelligent interest in the bigger world outside our borders. That is one reason why Mr. Bain's cheery effort to enlighten us will be keenly appreciated. We

like the emphasis on the home-like features of the country. The great gift of the miner to man has been not so much the production of metals as the opening up of new tracts suitable for the building of human nests, of places in which to work and to live, fresh opportunity and a new home. To the traveler the discovery that a name on the map is a human habitation is a surprise that no repetition can stale. By the time a man has been to a few corners of the earth and come back from them with recollections of homes and children, manly effort and womanly kindness, he begins to realize what the world is and how small a part of it his own bailiwick forms. That is the idea conveyed in a charming manner by Mr. Bain. He finds one part of South Africa not so unlike California, another recalls Colorado, a third suggests the uplands of southern Missouri. The chief difference is in the human element: the dominant factor is a large supply of cheap black labor. The economic value of the Kaffir is obvious, but, as Mr. Bain suggests, the general dependence of the white man upon the native for all manual labor is injurious to the moral fibre of the superior race. In one of his books H. G. Wells suggests that no man should go about with the marks of another man's toil on his person, for instance, a shoe-shine. To the author of 'Tono Bangay' the mansion that can boast three butlers is an absurdity. Undoubtedly the multitudinous retainers of an ancient civilization in Europe and the mob of black boys at the call of a mine manager in Africa are equally suggestive of a waste of labor, that is, the employment of men in unproductive tasks. Such conditions react on the employer, rendering him slothful and eventually ineffective. Mr. Bain's remarks on the inefficiency of both the white and the black labor on the Rand and in Rhodesia are most interesting. He explains some of the reasons for the unsatisfactory conditions. The over-supply of Kaffirs and the squandering of this economic resource is described in moderated language but none the less vividly by our observant friend. Here surely is something to which the Union Government should give serious attention, for South Africa is wasting its patrimony. Next Mr. Bain touches upon the racial problems arising from the relation of the horde of black natives to the small white communities, the relation of the Dutch to the British, and the more recent difficulties made by the East Indians, whose incursion into Natal reminds him of the trouble caused by the Japanese in California. There, as here, the conflict of races is not only a political but an economic factor that must be taken into account by those engaged in business. However, Mr. Bain concludes on a note of friendly optimism and tells the adventurous that South Africa is a land rich in opportunity, as in sunshine, Kaffirs, and menagerie beasts. We feel assured that those who read Mr. Bain's article will have glimpsed a fascinating land and that they will join us in the hope that the gastro-nomic items mentioned by him, incidentally, will have had a beneficent effect on his health, for the readers of this paper, we know, wish him good health and happiness always.

An American's Impressions of South Africa

By H. Foster Bain

He is a most unusual visitor who does not land at Capetown with his head full of misinformation about Africa. Despite well-meaning efforts on the part of fellow-passengers, the handicap of past reading is not to be overcome even in the 17 days' voyage from London. Most of us began our studies of Africa by the aid of those thin flat books of generous width of page upon which we were wont to stack our readers and arithmetics when the inevitable day came that 'school took up again.' In such books Africa was a large blotch of variegated color. Within its limits a few lakes were placed, though well toward the centre and fairly secure from accurate observation. Over its surface a few rivers found their uncertain way, and Cairo, Timbuctoo, and Capetown were given equal and impartial prominence. Political boundaries were almost as indefinitely traced as the rivers, and there are geographies still in use in which the South African republic maintains its independence, for a fact must be mature indeed to find its way into some text-books. On this meagre foundation we added a reading of Rider Haggard and Stanley, both informing and stimulating but neither exactly descriptive of Africa as it exists today. Perhaps, too, our youthful impressions were colored by the tales of some returned—I almost said 'reformed'—missionary, who dilated upon the trials and tribulations of work among the 'heathen' in 'the heart of the great black continent.' How often that resounding phrase has been made to do duty. Almost certainly our imaginations were fired by the tales of the big-game hunter, who artfully leads one to infer that from the Cape to Cairo is one unending Hagenbeck domain, mims the bars and keepers. One comes to associate 'elephant guns'—whatever they may be—with Africa as closely as bread with butter, and finally reaches a mental state when it is almost as unthinkable to start for that country without fire-arms as to attempt a ramble through rural England without a walking-stick.

It is on such a background that most of us have projected our later information about Africa. The period of company reports ushered in by the coming of the Rand, gave, it is true, a deluge of facts but without any adequate increase in information. Even when our data are correct they are more apt than not to be wrongly assembled and correlated. To one who has never been on the Rand, 'Randfontein' and 'Reitfontein' sound much alike, and unless he reads with always a map before him, which few are careful to do, facts get curiously tied up with the wrong property. Several thousand miles away it is difficult to realize that two properties which sound so much alike lie really as far apart as Cripple Creek and Colorado Springs, and that while of the same general

type, they are as unlike as the Dome mine is from that at Kirkland Lake. The resemblances between Sheba and Shamva have also misled many a careless reader who knows nothing at first-hand of distances in Africa. It is worth while to journey from London to South Africa and back if only to become mentally oriented in such matters; it is much more worth while for any mining man who has a broad interest in his profession and a keen human interest in the problems of a growing democracy. His visit will be one continuous series of stimulating experiences, and a not inconsiderable part of his time will be devoted to being set right as to things he had got wrong.

It is a trait of human nature to dwell on the unusual. It has been largely owing to this that progress has been made, for it has been by picking out the exceptional and so devising as to make it the ordinary, that better conditions have been made general. Commendable as this is, there are limits to the usefulness of the process. Most of those who have written of Africa have devoted major time and space to the things which in actual life in that country are really out of the ordinary. Lions and cannibals have been the stock properties of the writers. One may freely admit that to him who goes venturing, adventures fall, but, armed with a vivid imagination and a Cook's ticket, one may experience thrills in any land. An experiencing nature has experiences, while the ordinary citizen lives an ordinary life, in Africa as in Britain or America, and the bulk of the men and women one meets are ordinary citizens. I should not argue strongly from the limited experience of a short trip but, traveling over 8000 miles in Africa by all sorts of conveyances, and over high, low, and middle veldt, I never saw or heard a lion. This might not mean much, since I certainly was near them at times, but repeatedly friends of twenty years of more varied experience in the country assured me that their only sight of lions had been at the Zoo in Regent's Park. As for cannibals, one needs only to see the native's devotion to 'mealies' to feel confident that whatever may have been true in the past 'long pig' is by no means now a regular article of diet. Indeed the strongest and most lasting impression brought back from South Africa is of its likeness to other countries, and its entire liveableness. It is a country of homes—a country where men and women just such as you and I and our wives have their homesteads or bungalows, where children are born, grow up, go to school, and become in time men and women, with never a thought that they are temporary exiles from some more favored country. The South African loves his country and is proud of it, with a jealous and well justified pride. He resents it being considered one of the ends of the earth

where one may go to amass a fortune, but where no one not obliged to do so would think of remaining, and to one who has lived in other pioneer countries and comes by his liking for them naturally, this feeling seems the only possible one. It is only city dwellers who would be lost in any country, or those hopelessly untransplantable people to whom no place is ever like the old one, who find Africa unthinkable as a home. To a man with any ordinary degree of adaptability or any usual ability to assimilate, the new country offers a bewildering variety of stimuli and impressions out of which to build a life that can never stagnate.

It is an old saying that every farmer thinks life would be easy if he only had a gold mine, while every gold-miner looks forward to spending his declining years on a farm where, either with pigs and alfalfa, chickens or oranges, he has nothing to do but eat, sleep, and rest from his exertions, while nature provides. California has an enviable reputation among mining-men as the fairyland to which all good engineers are translated in this life whatever may be their chances in the life to come, but as I visited the Cape and drove from sea-point to Hout Bay, over to Muizenberg, and back along the high road to the Mt. Nelson hotel, I wondered whether California has not an unsuspected rival. There is the same panorama of sea, mountain, and sky, the same bewildering variety of flowers, the same beautiful smooth roads shaded by long rows of tall trees which meet in an archway overhead, and the same series of charming little houses interspersed with the more pretentious places of those of greater wealth. For the Mexican missions, the old Dutch homesteads afford a substitute, and for the Chinese and Japanese, there are the East Indians and the 'colored people' in every shade and hue, as well as in every color and cut of garment. Life must be interesting when there is so much of contrast and comfort and, on extending my journey to other old settled parts of the Cape, the conviction grew that here is a place in which a man might settle down and take his ease in comfort. The same may be said of many other parts of the country. Johannesburg is much such a city as Denver; and Bulawayo, with its wide wind-swept streets and constant talk of cattle, is reminiscent of Cheyenne. The Katanga is to most people a far-off country of hard living conditions where amid 'geological nightmares' a few pig-headed people are attempting with no skill and little information to make copper. Actually, it is a replica of the Ozark country in which the wealthy citizens of St. Louis and other knowing ones have built summer houses. The geology proves to be unusual only in the great size and richness of the orchidies, and the supposed pig-headed ones are well-trained engineers who are conducting highly-skilled technical operations under conditions that are a bit trying for the present, it is true, but which they are meeting with eminent success. Riding in a comfortable automobile to a tennis tournament, or sipping tea with your hostess in a big comfortable living-room, it seems a minor matter that a leopard last night carried off the pet dog of the assistant-manager from before his very

eyes. Such things do happen, but they do not interfere with the general smooth and even course of a pleasant existence. It is this general liveableness and likeableness of the country that one must get fixed in the background of his mind if he would correct the false impressions of the past.

The second point that is quickly borne in on the visitor is that the average standard of comfort in South Africa is high, at least around the mines. In current phrase they 'do themselves well.' It is not merely that in Johannesburg even the shift-bosses have high-powered autos and the miners are the chief supporters of racing, but the average scale of white man's living is much above that in England and most parts of America, as proved by the figures of the Economic Commission. The houses, it is true, are small and simple, for building-materials are expensive. They are neither so large as in England nor so convenient as in America, but they are sufficient for an out-door country and they are surprisingly comfortable. Even a galvanized iron tank with a thatched roof and a cement floor makes over into a delightful room, one well adapted to the special conditions of the country. Food is varied and abundant. For a while at least I got away from the steady succession of boiled cabbage and potatoes that marks the too common limit of incursions into the vegetable kingdom in England in war-time. In South Africa peas and other vegetables are regarded as articles of food and despite the fact that 'mealies' (the local name for corn) is regarded as Kaffir food, I did at rare intervals taste roasted ears. All this wandering into untravelled gastronomic fields is possible, too, without getting out of reach of the roast beef which binds the Empire together or missing the bacon and eggs on which the sun never sets. South Africa does not yet raise all the food it requires, but, enjoying as it does a large income, it imports liberally anything lacking and even the most persistent of thin men visiting the country takes on flesh and fills out his gaunt frame.

The secret of comfort in South Africa, as also the heart of many other things peculiar to the land, is the presence of enormous numbers of black men. Untrained and ignorant of our ways as they are, they are so numerous that none are too poor to have at least one servant, and in most homes the head of the house is surrounded, like a chief of old, by a very cloud of men at hand to do his bidding. 'Let the boy do it' is about the first phrase in South Africa that a visitor hears, and 'the boy' is so numerous, so patient, and so willing, that the white man soon gets out of the way of doing anything that requires mere labor. 'The white man,' the boy says, 'works with his finger,' meaning thereby that he points out merely what some other person must do. While this does not tell the whole story, it still is largely true and in South Africa white men achieve comfort with less hard labor than in any country that I know. This mere physical comfort of living is the second point that impresses the visitor after he overcomes the first feeling of repugnance to having everything done for him. It may all be very wrong and demoralizing to both white

and black, and it may, nay probably does, involve much putting up with things poorly done, but it certainly is comfortable.

This abundance of personal service brings to mind the third impression, and it is not so pleasant. It is that of the waste in labor. Everywhere I heard of the scarcity of labor, everywhere I saw the waste and inefficiency of that which was employed. There is some attempt to economize in the number of white workers, though even here strong white men are employed to do what would be black man's work elsewhere or at least the work of boys, but there is not sufficient effort to see that the white man is efficiently used. His time is wasted and he is allowed to become slothful, waiting while 'the boy' does something he could do more quickly himself. The inefficiency of the white labor of South Africa is something

black into bad habits. Repeatedly on entering a stope the manager, mine captain, or whoever was guide, sent his personal black attendant around to stop all the machines so that conversation might be more easily conducted. If the conversation proved long and we all sat round and discussed matters to a conclusion, all the machines stood idle and the boys waited. It was a courtesy to the visitor and I would not want to seem ungrateful, but it did interrupt the work, and it at least seemed to be customary. There is not the drive to the work to which one is accustomed elsewhere and a readiness to accept excuses exists that seems appalling. It must be realized that working with raw savages many of whom

IN A NATIVE COMPOUND.

that must strike every visitor familiar with what white men can and do accomplish elsewhere. Even more appalling is the waste of black labor. Here it is not only that it is insufficiently trained, and for that there are many excellent reasons, but very little effort is made to economize in the number of boys used. At the time of my visit conditions were a trifle exceptional in that poor crops had driven an unusual number of boys to the mines and, the diamond mines being closed except for surface work, the gold mines had more than their normal complement. It is one of the anomalies of the situation that practically a mine manager must find work for all the boys applying; otherwise the flow of new boys being checked, the mine will suffer later. Therefore, work was being made for boys on all sides. And in other parts of the country and in other industries where different conditions obtained, the same over-abundance of labor was to be observed. I do not remember to have seen an underground station where there were not several black boys waiting, and repeatedly it could be noticed that when a task was finished no provision had been made in advance for moving the men at once to something else. This abundance of 'boys' leads white men as well as

PROSPECTING IN RHODESIA.

never saw a white man five years before and almost none of whom have any comprehension of, or interest in, his task, is a different matter from directing highly skilled white labor. It is also true that when the average term of black man's service is eight months, and a discouraging number of white miners drift along the 'reef' looking for a 'snap' and working but a month at a time in one property, it is almost impossible to build up a real organization, still it seems not unfair to say that too many merely take the easy way and pile more 'boys' on the work, thereby helping to perpetuate bad conditions and ruining natives who might become good workmen. This unsatisfactory condition of the labor situation is one of the phases of work in South Africa that is forced over and over upon one's attention.

Race problems are the outstanding feature of South African life. To one who has always lived in a country

where one may go to amass a fortune, but where no one not obliged to do so would think of remaining, and to one who has lived in other pioneer countries and comes by his liking for them naturally, this feeling seems the only possible one. It is only city dwellers who would be lost in any country, or those hopelessly untransplantable people to whom no place is ever like the old one, who find Africa unthinkable as a home. To a man with any ordinary degree of adaptability or any usual ability to assimilate, the new country offers a bewildering variety of stimuli and impressions out of which to build a life that can never stagnate.

It is an old saying that every farmer thinks life would be easy if he only had a gold mine, while every gold-miner looks forward to spending his declining years on a farm where, either with pigs and alfalfa, chickens or oranges, he has nothing to do but eat, sleep, and rest from his exertions, while nature provides. California has an enviable reputation among mining-men as the fairyland to which all good engineers are translated in this life whatever may be their chances in the life to come, but as I visited the Cape and drove from sea-point to Hout Bay, over to Muizenberg, and back along the high road to the Mt. Nelson hotel, I wondered whether California has not an unsuspected rival. There is the same panorama of sea, mountain, and sky, the same bewildering variety of flowers, the same beautiful smooth roads shaded by long rows of tall trees which meet in an archway overhead, and the same series of charming little houses interspersed with the more pretentious places of those of greater wealth. For the Mexican missions, the old Dutch homesteads afford a substitute, and for the Chinese and Japanese, there are the East Indians and the 'colored people' in every shade and hue, as well as in every color and cut of garment. Life must be interesting when there is so much of contrast and comfort and, on extending my journey to other old settled parts of the Cape, the conviction grew that here is a place in which a man might settle down and take his ease in comfort. The same may be said of many other parts of the country. Johannesburg is much such a city as Denver; and Bulawayo, with its wide wind-swept streets and constant talk of cattle, is reminiscent of Cheyenne. The Katanga is to most people a far-off country of hard living conditions where amid 'geological nightmares' a few pig-headed people are attempting with no skill and little information to make copper. Actually, it is a replica of the Ozark country in which the wealthy citizens of St. Louis and other knowing ones have built summer houses. The geology proves to be unusual only in the great size and richness of the orchodies, and the supposed pig-headed ones are well-trained engineers who are conducting highly-skilled technical operations under conditions that are a bit trying for the present, it is true, but which they are meeting with eminent success. Riding in a comfortable automobile to a tennis tournament, or sipping tea with your hostess in a big comfortable living-room, it seems a minor matter that a leopard last night carried off the pet dog of the assistant-manager from before his very

eyes. Such things do happen, but they do not interfere with the general smooth and even course of a pleasant existence. It is this general liveableness and likeableness of the country that one must get fixed in the background of his mind if he would correct the false impressions of the past.

The second point that is quickly borne in on the visitor is that the average standard of comfort in South Africa is high, at least around the mines. In current phrase they 'do themselves well.' It is not merely that in Johannesburg even the shift-bosses have high-powered autos and the miners are the chief supporters of racing, but the average scale of white man's living is much above that in England and most parts of America, as proved by the figures of the Economic Commission. The houses, it is true, are small and simple, for building-materials are expensive. They are neither so large as in England nor so convenient as in America, but they are sufficient for an out-door country and they are surprisingly comfortable. Even a galvanized iron tank with a thatched roof and a cement floor makes over into a delightful room, one well adapted to the special conditions of the country. Food is varied and abundant. For a while at least I got away from the steady succession of boiled cabbage and potatoes that marks the too common limit of incursions into the vegetable kingdom in England in war-time. In South Africa peas and other vegetables are regarded as articles of food and despite the fact that 'mealies' (the local name for corn) is regarded as Kafir food, I did at rare intervals taste roasted ears. All this wandering into untravelled gastronomic fields is possible, too, without getting out of reach of the roast beef which binds the Empire together or missing the bacon and eggs on which the sun never sets. South Africa does not yet raise all the food it requires, but, enjoying as it does a large income, it imports liberally anything lacking and even the most persistent of thin men visiting the country takes on flesh and fills out his gaunt frame.

The secret of comfort in South Africa, as also the heart of many other things peculiar to the land, is the presence of enormous numbers of black men. Untrained and ignorant of our ways as they are, they are so numerous that none are too poor to have at least one servant, and in most homes the head of the house is surrounded, like a chief of old, by a very cloud of men at hand to do his bidding. "Let the boy do it" is about the first phrase in South Africa that a visitor hears, and 'the boy' is so numerous, so patient, and so willing, that the white man soon gets out of the way of doing anything that requires mere labor. "The white man," the boy says, "works with his finger," meaning thereby that he points out merely what some other person must do. While this does not tell the whole story, it still is largely true and in South Africa white men achieve comfort with less hard labor than in any country that I know. This mere physical comfort of living is the second point that impresses the visitor after he overcomes the first feeling of repugnance to having everything done for him. It may all be very wrong and demoralizing to both white

and black, and it may, may probably does, involve much putting up with things poorly done, but it certainly is comfortable.

This abundance of personal service brings to mind the third impression, and it is not so pleasant. It is that of the waste in labor. Everywhere I heard of the scarcity of labor, everywhere I saw the waste and inefficiency of that which was employed. There is some attempt to economize in the number of white workers, though even here strong white men are employed to do what would be black man's work elsewhere or at least the work of boys, but there is not sufficient effort to see that the white man is efficiently used. His time is wasted and he is allowed to become slothful, waiting while 'the boy' does something he could do more quickly himself. The inefficiency of the white labor of South Africa is something

black into bad habits. Repeatedly on entering a stope the manager, mine captain, or whoever was guide, sent his personal black attendant around to stop all the machines so that conversation might be more easily conducted. If the conversation proved long and we all sat round and discussed matters to a conclusion, all the machines stood idle and the boys waited. It was a courtesy to the visitor and I would not want to seem ungrateful, but it did interrupt the work, and it at least seemed to be customary. There is not the drive to the work to which one is accustomed elsewhere and a readiness to accept excuses exists that seems appalling. It must be realized that working with raw savages many of whom

IN A NATIVE COMPOUND.

that must strike every visitor familiar with what white men can and do accomplish elsewhere. Even more appalling is the waste of black labor. Here it is not only that it is insufficiently trained, and for that there are many excellent reasons, but very little effort is made to economize in the number of boys used. At the time of my visit conditions were a trifle exceptional in that poor crops had driven an unusual number of boys to the mines and, the diamond mines being closed except for surface work, the gold mines had more than their normal complement. It is one of the anomalies of the situation that practically a mine manager must find work for all the boys applying; otherwise the flow of new boys being checked, the mine will suffer later. Therefore, work was being made for boys on all sides. And in other parts of the country and in other industries where different conditions obtained, the same over-abundance of labor was to be observed. I do not remember to have seen an underground station where there were not several black boys waiting, and repeatedly it could be noticed that when a task was finished no provision had been made in advance for moving the men at once to something else. This abundance of 'boys' leads white men as well as

PROSPECTING IN RHODESIA

never saw a white man five years before and almost none of whom have any comprehension of, or interest in, his task, is a different matter from directing highly skilled white labor. It is also true that when the average term of black man's service is eight months, and a discouraging number of white miners drift along the 'reef' looking for a 'snap' and working but a month at a time in one property, it is almost impossible to build up a real organization, still it seems not unfair to say that too many merely take the easy way and pile more 'boys' on the work, thereby helping to perpetuate bad conditions and mining natives who might become good workmen. This unsatisfactory condition of the labor situation is one of the phases of work in South Africa that is forced over and over upon one's attention.

Race problems are the outstanding feature of South African life. To one who has always lived in a country

where your fellow-citizens, if they do not agree with you—and generally they don't—at least think by the same general processes, are influenced by the same ideals, and actuated by the same general purposes as yourself, South African life is a puzzle. Having always thought in certain ways yourself and lived with people who accepted most of your own premises, it comes as a shock that there are people in the world, and in numbers sufficient to make it necessary to take them into account, who, if they do not actually deny that two and two make four, at least have no knowledge of, or interest in, any number above four. To the Canadian, with his experience in fitting government to people of both French and British descent, the Dutch-British problem is an old one. The French of Canada have their affiliations with the France of long ago and have fitted themselves to their environment, just as the Dutch of South Africa hark back to a Holland that has disappeared and have been moulded by their life into a different people from the modern Hollanders. To the American with his experience with Indians under tribal conditions and with negroes in the Southern States, the white-black problems of South Africa seem all part of his past existence. But no people other than those of South Africa have been called upon to face at one time the race problems that are so disturbing features of life in both Canada and the United States. Added to this is the fact that, while in Canada the French are in the minority, in South Africa the Dutch have a clear majority. In the United States, while the total number of black men is about the same as in South Africa south of the Zambesi, they are only as 1:10 in total population and about 2:1 in the States where most numerous, while in South Africa they vastly outnumber the whites. Just as on the western coast of both Canada and the United States there are enough Asiatics to complicate the situation, so in Natal and elsewhere in South Africa the East Indian fellow-subjects of the Empire have come in to demand a place. A still further complication is that whereas Canada and the United States stand off somewhat alone, and the two peoples who in the main think alike are free to settle their race problems as they see fit, the British territories of South Africa are hedged in by those of Portugal and Belgium, in both of which the attitude toward natives and race admixture is markedly different from that in Rhodesia and in the Union. There has been a further complication due to the presence of the Germans, but what that may amount to in the future is beyond ken. These numerous and overpowering race problems enter into every phase of life in South Africa. One cannot go far in any direction without facing them and cannot investigate any problem, be it ever so technical, without taking them into account. They are kaleidoscopic in their phases and studying them is much the most fascinating problem in existence to any one who either lives in or visits the country.

I may say at once that I do not believe that they will be solved immediately or by any set rule. It will only be by slow steps and through long years that relations

will come to be adjusted. What the end will be can only be guessed and in the meantime those of us whose homes are outside the country, but who may have some definite interest in it, cannot do better than to stand aside and watch with the keenest and most sympathetic interest the struggles of those who face the problems on the ground. It is impossible, however, to think of South Africa without taking race problems into account, and each must form for himself a working hypothesis as to the changes likely to ensue in the next ten or twenty years, the period over which most of us plan investments. We may go wrong, doubtless we shall in large part, but we must come to some conclusion or else stay wholly outside the country. Perhaps the most powerful impression obtained in South Africa is of the necessity and importance of considering race problems when planning a business enterprise.

And lastly, are there opportunities in South Africa? That is what it all comes back to for those of us who are still outside, who have not committed ourselves as yet to the venture of money or person in the country. Without hesitation, I may answer Yes. The opportunities stare one in the face from the day of landing to the moment when the steamer backs away from the Cape-town quay and starts on the home voyage. Readers of the MINING AND SCIENTIFIC PRESS need little education as to the mining possibilities of the country, but I may suggest that it is by no means true that all the mines have been found or all those found have been developed. Money is needed at many points to start the wheels of industry in mining as well as for other ventures. I am not competent to judge as to agriculture, but certainly there are considerable areas of seemingly fertile land which are either not cultivated or are so poorly tended as to be virtually wild, and certainly such farmers as I met seemed by all outward signs to be doing quite as well as they deserved. Men as well as money, however, are needed; men of experience, ability, and ideals above the achievement of enough wealth to permit the owning of a string of race-horses. The country needs roads and road-makers in many a sense. It has its big men, but here as elsewhere there is abundant room at the top and men with creative ability are needed. To such men the country will yield large returns. Without facing the question as to whether Africa is to prove a white man's, a black man's, or a brown man's country, I may say unhesitatingly that there is room for many more white men than are now in the country, provided they be of the sort that makes pioneers. Such men will find a thinly occupied field, many natural resources lying unused, and a most friendly hospitable people to welcome them. With the wide sweep of the veldt in front, and glorious sunshine above, they can feel that here they start even in life and with a fair chance to win the race.

DIVIDENDS paid by Rand companies in the first half of 1916 amount to £3,631,795, compared with £3,845,036 in the same period of 1915. Far East Rand mines made increased distributions.

Pocket-Hunting Applied to Prospecting

By John E. Platts

A method commonly used for prospecting hidden veins that do not outcrop seems to be unfamiliar to so-called 'engineer-prospectors.' This is 'rimming' with a pan as practised by the 'pocket-hunters' for gold.

Gold pockets are concentrations near the surface, or at least in the oxidized zone. They commonly occupy a small space such as a vug in a quartz stringer or in a small, partly open fissure. The gold is usually loose and free from gangue, which is likely to be clay and decomposed rock minerals mixed with oxides of iron and manganese and, in the deeper pockets, with secondary sulphides. In true pockets the proportion of gold to gangue is considerable, amounting to solid metal in extreme cases. Large placer nuggets are probably derived from such pockets. There is abundant evidence that these pockets are secondary deposits derived from near-by low-grade primary deposits. The gold-pockets are found in 'iron seams' and iron-bearing quartz veins and less often in calcite stringers. The pocket-hunter pays special attention to yellow spots or streaks in the alluvium, as these indicate a concentration of iron. Sufficient ferrous sulphate may be present to form a gold-pocket and not make a distinct coloration in the soil. Hence in a favorable-looking region or near where pockets have been found in the past, it is customary to do systematic prospecting over considerable areas regardless of the color of the ground. Ferrous sulphate is the most common precipitant of gold chloride in solution in meteoric water, the gold having been dissolved by chlorine set free by the action of oxides of manganese on soluble chlorides, this being the theory of formation.

The word 'trace' is used as by pocket-hunters, meaning the spill of gold in the surface-soil. The process of sampling a trace is called 'rimming' or tracing. When the pocket-hunter finds a yellow spot on an otherwise favorable hill-side, he spades up a shovelful of earth and pans it carefully. The presence of one or two fine colors is enough to cause him to thoroughly investigate the neighborhood. He takes a row of samples along the hill-side, three or four feet apart and following a contour. If he is on a real trace several of these probably will show more or less gold, while the end-samples of the row will be barren. If a large number show gold, that is, if the trace is wide, it will mean one of three things: (1) that the pocket is some distance up the hill, (2) it is an unusually large one, and (3) the gold comes from a vein in which it is not concentrated in pockets. The first contingency is the most probable, and the third next; big pockets are rare. The pocket-hunter then takes another row of samples a short distance higher up the hill than the first row. It is not necessary this time to take the extreme end samples much beyond the limits of the trace as shown by the first row of samples. If the pocket is near by, the strip of soil carrying gold will

narrow rapidly as one goes up hill. If the trace comes from a true pocket it will contract to a width of a few feet as the prospector takes successive rows of samples. Here he must move slowly and cautiously, as the pocket may be in the surface soil and contained in a space no bigger than a shovelful. It is easy to overlook such a pocket, or unwittingly shovel it down the hill. However the pocket is usually found in the bed-rock. A point will be found where no gold appears on the surface. Deeper digging for the next row of samples will show that the trace is still there, and a careful examination reveals a layer in the soil of a different color to the rest, commonly more yellow. The gold will be confined to this yellow layer and to a narrow strip of it. At this point the experienced pocket-hunter begins to pan the entire gold-bearing streak instead of only samples, to avoid shoveling the pocket over the dump. Inexperienced pocket-hunters lose much gold by neglecting to observe this precaution. The gold-bearing layer will be found to approach bed-rock as it is followed until it lies upon it, and finally stops at an iron seam or quartz stringer or vein of calcite. After finding the vein that contains the gold, the prospector continues to dig and pan all the gold-bearing material until the pocket or pockets are unearthed. A single stringer will often contain several pockets.

If the ground is flat the surface-soil is likely to be deep, and the amount of digging below the surface will be extensive. If the hill-side is steep, the surface-soil will be thin or absent in spots, and when a trace passes over a bare spot it is difficult to follow. Surface slides often complicate traces. A close inspection of the colors with a lens will tell the experienced pocket-hunter whether a trace is worth following. True pocket gold is rough and ragged, often appearing like fragments of finely branched moss. Smooth grains like tiny seeds or flakes are likely to lead to unprofitable scattered deposits in talc or serpentine.

Pocket-hunters are sometimes embarrassed by overlapping traces, that is, traces from several sources mingled in the same soil. The expert can often untangle overlapping traces by examining the gold and noting differences in color. Natural gold from different deposits is likely to vary more or less in the color due to alloyed impurities.

The method of the pocket-hunter can be used to advantage by the man prospecting for larger gold ore-shoots. Such are likely to be found in the softer and less resistant portions of veins, and hence are often covered with surface-soil. A large deposit does not throw a narrow trace like a pocket, but a more scattered layer of finer gold. When, for any reason it is suspected that an ore-shoot may apex on a given hill-side, a systematic rimming will find it or prove its absence. This prospecting method may be applied to the search for cinnabar, tungsten minerals, and cassiterite. Where base metal sulphides appear at the surface, lead, copper, and iron sulphides may be panned from the surface soil below an apex.

PLAN OF PROPERTIES ON DOUGLAS ISLAND, ALASKA.

Consolidation of the Treadwell Mines

[Herewith we give abstracts from the report by a committee of engineers, composed of Messrs. H. C. Perkins, Hennen Jennings, and F. W. Bradley, who were called upon to advise on the consolidation of the Alaska Treadwell, Alaska United, and Alaska Mexican companies; operating contiguous mines on Douglas island, Alaska.]

THE ANNUAL REPORTS of the three companies have been carefully studied. Since 1890, these annual reports have given the most comprehensive and generous information, and as they have mirrored the successful accomplishment of gold mining upon the lowest-grade ore exploited until recent years, these reports have historic as well as present practical value. [The Ready Bullion and 700-Foot claims belong to the Alaska United company.]

The summary of returns from each mine, from the starting up to June 1, 1916, are as follows:

TREADWELL

Tons crushed	16,966,702
Total yield	\$38,803,810.85
Total yield per ton	2.41
Operating profit	17,907,530.28
Operating cost per ton	1.31
Operating profit per ton	1.10
Total dividends paid	15,785,000.00
Dividends per ton	0.99

READY BULLION

Tons crushed	3,802,209
Total yield	\$7,910,191.25
Yield per ton	2.08
Operating profit	1,966,011.57
Operating cost per ton	1.57
Operating profit per ton	0.51
Dividends per ton	0.338

700-FOOT

Tons crushed	2,239,833
Total yield	\$4,644,316.34
Yield per ton	2.07
Operating profit	1,086,288.58
Operating cost per ton	1.59
Operating profit per ton	0.48
Dividends per ton	0.339

Alaska United dividends total \$1,991,210.

MEXICAN

Tons crushed	4,355,213
Total yield	\$11,438,812.47
Yield per ton	2.62
Operating profit	4,078,748.64
Operating cost per ton	1.68
Operating profit per ton	0.94
Total dividends paid	3,507,381.00
Dividends per ton	0.81

The grand total summary of accomplishment of all the mines for the period of their whole history is as under:

Tons crushed	26,464,047
Yield	\$62,797,459.91
Yield per ton	2.37
Operating profit	25,038,579.07
Operating cost per ton	1.42
Operating profit per ton	0.95
Dividends	21,337,651.00
Dividends per ton	0.805

If the returns for the years 1914 and 1915 and the first five months of 1916 be compared, they will show as under:

	TREADWELL			Jan. 1 to June 1 1916		
	1914	1915		1916		
Total yield	\$2,367,561.71	\$1,828,723.49		\$642,900.86		
Yield per ton	2.60	2.03		1.66		
Operating profit	1,386,119.36	718,521.13		195,346.73		
Operating cost per ton	1.08	1.23		1.32		
Operating profit per ton	1.52	0.80		0.34		
	MEXICAN					
Total yield	509,023.61	379,796.82		111,308.87		
Yield per ton	2.18	1.75		1.31		
Operating profit	170,020.18	99,476.75		1,086.58*		
Operating cost per ton	1.15	1.29		1.56		
Operating profit per ton	0.73	0.46		0.22*		
	UNITED (READY BULLION)					
Total yield	531,497.68	521,912.25		253,661.85		
Yield per ton	2.29	2.07		2.09		
Operating profit	191,827.34	192,738.40		85,561.98		
Operating cost per ton	1.47	1.31		1.39		
Operating profit per ton	0.82	0.76		0.70		

UNITED (700-FOOT CLAIM)

Total yield	431,383.89	520,262.50	171,952.29
Yield per ton	1.91	1.85	1.93*
Operating profit	66,112.24	151,253.99	27,563.75*
Operating cost per ton...	1.62	1.31	1.96
Operating profit per ton.	0.29	0.54	0.27*

* Loss.

THE ORE RESERVES ARE AS FOLLOWS:

	Tons	%
Treadwell	7,012,755	44½
Mexican	1,188,866	7½
Ready Bullion	2,583,105	16
700-Foot	4,893,908	31½
Total	15,678,634	100

It will be noted that for the ore in place (which includes pillars) and also for the broken ore, no valuation is given, nor can it be given accurately, but an estimation has been made by the general superintendent, Mr. R. G. Wayland.

This valuation is really on the basis of salvage, that is, no development costs are included and all charges preparatory to future exploitation are omitted. A summary of his valuation is given and discounted to present value by 6% annuity-tables with rough estimates of the time required to extract the ore, as under:

Mine	Tons	Profit per ton	Total profit	Present value per ton	Present value
Treadwell	3,000,000	\$0.46	\$1,368,000	\$0.41	\$1,231,000
Mexican	50,000	0.30	15,000	0.30	15,000
700-Foot	2,400,000	0.28	666,000	0.25	598,000
Ready Bullion...	1,560,000	0.94	1,470,000	0.64	992,000
Total	7,010,000	\$0.50	\$3,519,000	\$0.40	\$2,836,000

The factor of caving possibilities in the future is most serious. It is thoroughly discussed by Mr. Wayland, and will be referred to later in this report.

The geological cross-section of the Ready Bullion, showing the position of the old shaft and Gastineau Channel, explains graphically the high discount given to the pillar-reserves of this mine and the reason for the abnormal proportion of ore held in reserve in pillars compared with the ore milled; but it is to be noted that a greater present value is allowed for the ore reserves in this mine than the mine has earned in dividends during its life of 18 years.

Costs. The annual reports have given, in much detail, the operating and other costs of the various departments over long and varied periods; but to make fair comparisons between periods or hazard future forecasts, more than periodical results must be known and taken into consideration.

While working stopes, mining conditions make it imperative that only one-third of the ore so broken can be drawn for the mills. Therefore in some periods of disappointing development, it is difficult to have a sufficient number of new stopes in progress to maintain a mill feed consisting of normal proportions of freshly broken ore, broken ore in reserve, and caved ore from pillars. In time of supposed plenty, if underground

conditions seem favorable, the temptation is great to reduce the accumulation of broken ore; and under other circumstances on account of lack of profitable ore to start new stopes, the amount of broken ore does not correspond with the mill demands owing to the impossibility of opening enough stopes to maintain the supply. Should shaft, general development, and stope work be allowed to get behind, such arrears must be made up in later periods, and future costs are thus adversely affected. At the present time the Treadwell, the Seven Hundred, and the Mexican mines are in the unfortunate condition of being unable to make a good showing of tonnage unless a trespass is made upon pillars and reserves of low-grade ore.

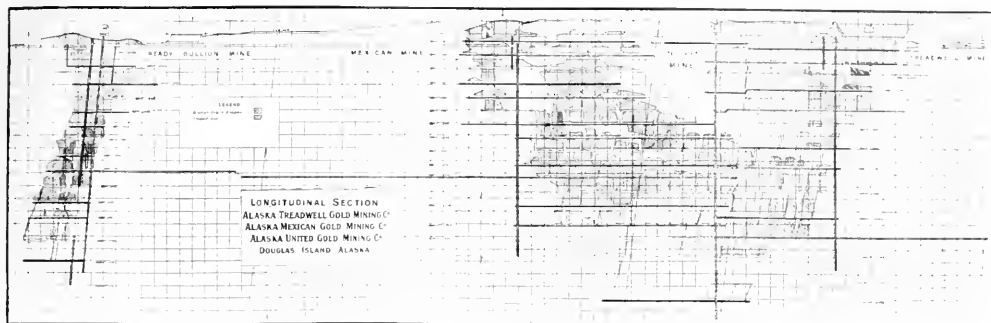

When there is a serious fall in the yield of a mine and a lower grade of ore than has been successfully worked in the past is all that is available, self-preservation prompts the making of an extra effort to reduce the working cost, even if it demands new capital outlay. This is justifiable, provided there is positive assurance of sufficient quantities of ore being available to redeem the extra expenditure incurred.

The Alaska Juneau and Alaska Gold companies, operating on the mainland opposite Douglas island, have both been able to make a showing of a much lower working cost. The Alaska Gold Mines Company has definitely set forth the possibility of reducing the total working cost to less than 70 cents per ton; but to do so this company has incurred a capital outlay amounting to some \$7,000,000. The Alaska Juneau is engaged in developing its mine on a daring but sound caving system by which it is believed even a cost lower than that claimed by the Alaska Gold Mines can be obtained; but here the mine development and mill construction work in progress demand an expenditure of \$4,000,000.

It has been our privilege to inspect the workings and plants, as well as the maps and accounts, of both of these companies. We are satisfied that they will achieve a new record for low cost in gold mining. We are also satisfied that the mining conditions presented by them are not comparable closely with those existing at Treadwell, where the rock is harder to drill and less favorably adapted to the caving method. These mines on the opposite shore are so developed that the lowest level is several hundred feet above the bottom of the mill; thus they have no costly hoisting or pumping equipments nor the cost of operating such machinery, coupled with increased temperatures due to increment in depth.

The metallurgical methods as employed at present in the Alaska Gold mill are slightly cheaper than at Treadwell, but this is off-set by the greater pro-rata loss in the tailing. The extraction at Treadwell is 89.86% as compared with 81.06% in the Alaska Gold mill.

The feasibility of lowering costs by new equipment both underground and at surface at Treadwell has been considered carefully by the consulting engineer, Mr. P. R. Bradley. He has a thorough knowledge of the Alaska Juneau—Alaska Gold practice and accomplishments, and, as manager of the Alaska Juneau, he is conversant

SECTION SHOWING UNDERGROUND WORKINGS; THE SQUARES REPRESENT 100 FEET ON A SIDE.

with the possibilities of making even a better showing for your companies. His tentative and preliminary estimate for a combination plant sets forth the following saving in operating costs:

Mining:	Per ton	
Stopping	\$0.122	
Tramming	0.032	
Hoisting	0.026	
Pumping	0.001	
		\$0.181
Milling:	Per ton	
Crushing	\$0.012	
Tramming	0.009	
Stamping	0.063	
Concentrating	0.035	
		\$0.119
		\$0.300
Concentrate expense		\$0.024
Total saving per ton		\$0.324

The capital expenditure required to obtain these savings would be \$1,356,462.

This seems to us a sanguine estimate, but it is illuminating in that it suggests the maximum reduction of working expense. The report is most able and interesting, but the expenditure involved would only be justified by the certainty of an adequate reserve of profitable ore. Since writing his report, Mr. Bradley has given closer study to other problems connected with the mines and he is now in hearty accord with us; that new mill-equipment should await more assured and better mining disclosures and in the meanwhile surface improvements be kept to a minimum. On the other hand, we agree with him in recommending a larger expenditure underground.

ACCOUNTS. Appended herewith are valuation statements of the independent surface and other equipment of each company and of the proportionate interest of each company in the joint facilities and utilities as prepared by Mr. H. A. Pinger; and also statements of the cash assets and liabilities of each company, exclusive of its properties and plants, as prepared by the Secretary, Mr. F. A. Hammersmith. These statements show that the cash assets, after deduction of liabilities, of the three companies amount to \$1,584,868. And they show the

surface equipment and joint utilities to have a valuation of \$4,745,331, the grand total being \$6,330,200. The expenditure necessary for the full equipment of the mines to their present crushing capacity of 4850 tons has amounted to practically \$1000 per ton of daily capacity.

Comparing these statements with those contained in the annual reports, the reason for the operating profit being in excess of the dividends is apparent.

ORGANIZATION. The Douglas Island mines have been managed in the past as if they had been owned by one company. The Treadwell has been the pioneer, or parent, of the group. It has played the part of banker for the other companies, and has enabled them to obtain a large amount of their equipment and facilities from operating profits. The dates of the starting of the various companies are as under:

Alaska Treadwell	1889
Alaska Mexican	1891
Alaska United	1894

The Treadwell company owns the stores, machine-shops, foundry, original water-power, original wharves, boarding-houses, etc. It has furnished and supplied the other companies with such necessities at a moderate percentage above cost.

All of the supply departments sell goods to the public in general through the store, the latter getting the benefit of the extra profit over and above the departmental percentage. The store's profits accrue from supplies sold to the public at retail. Other departments show but small profits.

The President and Board of Directors of each of the companies are the same, as are also the head officials; differences are found only in a few minor departments. The Superintendent has no motive to favor one company more than another, and, as far as we can learn, the present or past superintendents have not done so knowingly. Such an organization has much to commend it in the way of reducing the overhead charges for each company and in obtaining high-class talent for each. In time of peace and plenty, this system has certainly worked effectively and harmoniously; but, should a time of stress and disappointment come, coupled with conflicting ownerships, there exist latent explosive possi-

bilities in such a co-partnership, especially when mixed with the Schedule 'B' arrangement.

MINING PROPERTY, UNDERGROUND CONDITIONS, AND OUTLOOK. The mining properties of the three companies are contiguous and interlocked, being situated upon and covering the lode-channel containing the ore-bodies.

The Treadwell group can be considered in two sections, the eastern and western. The eastern is distinct and known as the Ready Bullion mine, which is some 2400 ft. from the nearest exploited ground of the Mexican mine. Its problems and underground conditions seem distinct, although the lode-channel in all the mines is a dike-rock of similar character that may possibly have had the same origin.

The western section consists of the Treadwell, Mexican, and Seven Hundred Foot mines. They are in such juxtaposition and so merged together and influenced by similar conditions, that they should have had one ownership; but a compromise has been made in the union of management under one general superintendent, as has been already stated.

It would appear that the Ready Bullion is a diorite pipe with varying dip, and with varying swells and contractions, but of restricted area. The condition of the bottom of the mine is most favorable; in fact, the showing there is above the average both in tonnage and assay-value.

Although the amount of ore below the 2200-ft. level in the Ready Bullion (1800-ft. level, Treadwell datum) is merely a matter of guesswork, the fact that high gold contents have been found on the United's 700-ft. claim on the 2300-ft. level (4600 ft. to the west), or 500 ft. deeper, warrants an estimate of profitable ore below the present bottom; therefore an assumption of, say, 300 ft., to the 2100-ft. level seems fair.

To obtain some base-line for the estimate of ore below, the record of the mine offers the best basis. Consulting this, it will be found that the average profit per year for 18 years has been \$104,000, but with 40% of the ore left as pillars. Allowing a proportional valuation of the pillars on the basis of Mr. Wayland's estimate and a time allowance of six years for the work, an extra credit of \$370,000 should be given to the Alaska United's present total assets.

Though the Ready Bullion mine has at present a most encouraging outlook, it has not bulked large in dividends

little more than 6% of the total for the Douglas Island mines, as shown below:

	Dividends	%
Treadwell	\$15,785,000	73.98
Mexican	3,507,381	16.43
700	760,582	3.56
Ready Bullion	1,281,688	6.03
Total	\$21,337,651	100.00

The history, returns, and ore reserves of the western mines have already been given. The output of \$54,886,968 yielding \$21,337,651 in dividends, besides most of the cost of the present equipment, is certainly a

heritage of hope, which demands at least that all reasonable mining exploration should be continued before work is abandoned in this territory.

While there have been periods of depression and uncertainty in the past, especially between the years 1900-1902, there has never been such a critical state of affairs in the history of the companies as exists at present; nor one that demands as much hopefulness, skill, and good judgment from the management as well as larger hope and patience from the shareholders.

The Mexican mine may be obliged to suspend all milling operations in a few months on account of the lack of ore, and on its present lower levels there seems but little likelihood of finding further profitable ore.

From the Treadwell, Mexican, and 700 mines, below the 1600-ft. level, the proportion of ore sent to the mill was less than 1% in 1912, less than 0.5% in 1913, less than 1½% in 1914 and less than 2½% in 1915. The stopes above the 1600-ft. level are now about exhausted and the mills are being kept running largely by drawing on the reserves. The value of the ore developed and worked in the stopes below the 1600-ft. level has, on the whole, been most disappointing. Encouragement, however, should be taken from the fact that for the Treadwell the assay-value of \$1.85 on the 2100-ft. level is 39c. higher than the average of \$1.46 on the 1750-ft. level; and that for the 700 Claim, the average of \$1.80 on the 2100-ft. level is 86c. higher than the average of 94c. at 1750 feet.

The combined area of the orebody of the Treadwell and 700 mines, on the 2100-ft. level is greater than for any other level above.

A bore-hole recently run in the centre of the orebody on the 2300-ft. level has shown, for a distance of 272 ft., an average assay-value of \$2.40 per ton—a circumstance certainly most encouraging, as it demonstrates that satisfactory ore does exist at this depth. The 2300-ft. level has been but partly developed and it will be nearly another year before its true character is determined by the usual development and stoping work.

At the present time, development work and facilities for exploitation even on the 2100-ft. and 2300-ft. levels are by no means satisfactory. The danger of settlement of the machinery connected with the Central shaft, as also the possibilities of further changes in the alignment of the shaft by settlement are shown in the appended statement of the general superintendent. Men and materials are lowered from the No. 2 shaft of the Treadwell to the 1750-ft. level and then transferred some 1500 ft. to the Central shaft. This shaft has been enlarged below this level and one compartment added, which is served by an independent electrical winding-engine underground. Should cracking or caving prevent the operation of the Central shaft, from which a daily output of about 4000 tons is being hoisted, all exploitation would have to be suspended until a new shaft and equipment could be put into operation elsewhere.

It is only recently that a decision was made providing for the safe and thorough development of deeper levels. This is to be accomplished by the enlargement of the old

main Mexican shaft, now known as the Combination shaft, which work was started in January 1916.

In Mr. Wayland's appended statements will be found an estimate of cost and a time-schedule in relation to the development and opening of the 2500-ft. and 2700-ft. levels. This estimate shows that an expenditure of \$11,115,000 will be required and that the stopes will not be ready to be drawn until January 1922, or about 5½ years from now. It would appear that conclusive evidence as to the economic value of the orebodies in depth and the influence of the Starr dike cannot be looked for short of the 2700-ft. level.

In regard to the extra cost to be incurred as depth is gained, the most obvious are in the departments of pumping and hoisting. There being but little water in the mines and as the present cost of dealing with it is but two cents per ton, there appears no necessity for anticipating any serious increase in this item.

The cost of hoisting is 10 cents per ton, but with improved facilities, a reduction rather than an increase may be expected—at least on the 2500-ft. and 2700-ft. levels—but at the price of great capital outlay.

The following observations of temperature have been taken in the Treadwell mine:

Level	°F.	Level	°F.
990	58.6*	2100	73.1
1250	59.9	2300	78.0
1600	64.7	2300	76.0*
1750	68.0		

*Records were taken too near a shaft to be correct.

These temperatures were taken during the month of March 1916. The thermometers were sealed in drill-holes (varying from three to seven feet deep), and allowed to remain until a constant reading was noted (24 to 72 hours). An increment of about 1° for every 60 ft. in depth is indicated. This is not abnormal, but much greater than is found in the deep workings of the gold mines of South Africa and the copper mines of the Lake Superior region where the increment of increase is unusually small, not over 1° for each 200 ft. in depth. However, down to 4000 or 5000 feet working conditions can be made favorable by generous ventilation, but only at the cost of large capital outlay for equipment.

The factor of increased cost due to depth on the Witwatersrand, South Africa, shows the importance of ample ventilation, the difficulties in connection with extra pressure of superincumbent strata, the great extra

capital expenditure involved, and the economies effected by the consolidation of power.

All the foregoing conditions point to the absolute necessity of vigorous work on the Combination shaft, should serious deeper development be decided upon. The maps and section show the freedom of this shaft from caving. It is true that an incline shaft on the north-western side of the mine could be made to serve the same purpose, and should the Central shaft cave at some future time and much deeper exploitation be justified by encouraging development, it might still be necessary to sink it; but the quicker and cheaper plan is to continue the Combination shaft.

The difficulties and costs incident to deeper exploitation, even down to the 2700-ft. level, have been now fully presented. The main factor above all others is the persistence of the ore. All the factors bearing upon this problem have been considered, with, as a whole, more reason for discouragement than encouragement. At the depth of 2300 ft., having in mind the past records, it would appear that the 700 mine has the best possibilities in this regard, while the Mexican has the worst and the expectations of the Treadwell are limited. A careful study of the plans and geological sections and the inspection of the mines would lead one to conclude that the present trend of the gold-bearing dikes must change in depth, as these dikes may be restricted by, or be merged with, more barren dike-matter. The dike known as the Starr would seem to have a trend to the north-west and to have been a factor in the cutting or pushing out of the gold-bearing dike in the Mexican mine. If the Starr dike continues on its present course, it will interfere with the ore in the 700 mine at the 2300-ft. or 2500-ft. level, and at about 3000 ft. it will affect all the Treadwell and 700 orebodies. Assuredly it presents a serious menace unless conditions change in depth. There is, however, no certainty that at depth more favorable conditions will not supervene, and new orebodies may be found as good as those above. There is mere conjecture, but it points to the necessity of all three companies standing together and sharing in the risk and profit, on some established basis, of the deeper and costly exploration that must be undertaken.

SUMMARY AND DISCUSSION. The various visible assets of the three companies, with an allowance of ore for the Ready Bullion below its bottom level, can be summarized and tabulated as follows:

VISIBLE ASSETS						
Company	Surface equipment	Joint utilities	Cash assets less liabilities	Present value ore-reserves	Total	%
Treadwell	\$1,364,070	\$1,386,108	\$1,198,324.52	\$1,231,000	\$5,179,503	54.3
United	638,650	462,036	147,718.22	1,960,000*	3,208,445	33.7
Mexican	432,390	462,036	238,826.12	15,000	1,148,252	12.0
Total	\$2,435,150	\$2,310,180	\$1,584,868.86	\$3,206,000	\$9,536,200	100
*700-Foot above bottom	\$598,000					
Ready Bullion above bottom	992,000					
Ready Bullion below bottom	370,000					
	\$1,960,000					

In this statement, the valuations must not be taken as a basis of share appraisal, but merely as a guide for obtaining equitable proportions for a consolidation; and under the supposition that a large amount of work will be justified in the future.

The ore reserves have been discounted to present value by estimating future profits as annuities at 6%.

The development and assay-value of the ore on the bottom levels of the various mines are such that in none of them, with the exception of the Ready Bullion, does the showing justify any definite calculation of profitable ore below. There are, however, substantial grounds for hopes of betterment, as already stated.

The Ready Bullion ore-pipe on the lowest or 2200-ft. level (corresponding to 1800-ft. Treadwell) is 500 ft. long by an average width of 116 ft. with an average assay-value of \$3.37. This assay-value and the lack of any disturbing factor justify an allowance of about \$500,000 gross profit, with \$370,000 net present value as given by Mr. Wayland, even if a somewhat speculative credit is given to the outlook in depth. Ready Bullion has therefore been credited accordingly in the tabulation of visible assets.

However, such assay-values must not be taken as a mill return without modification: the loss in tailing has to be deducted and an allowance must also be made for a variable coefficient of average divergence from mine assays. These differences have been found as follows:

	Average mine assay value per ton	Mill and cyanide returns per ton
Ready Bullion	\$2.66	\$2.08
700 Claim	2.52	2.07
Mexican	3.05	2.62
Treadwell	2.53	2.41

An effort has been made to arrive at a basis for consolidation by giving certain assets preferential consideration over other assets, such as taking cash assets, less liabilities, at 100; and taking at 50 each the joint utilities, the surface equipment, the present value of ore reserves, and our ideas of future prospects. On this basis the proportion works out thus:

Treadwell	United	Mexican
53.81%	34.20%	11.99%

CONCLUSIONS AND RECOMMENDATIONS. We have considered all the factors bearing upon the present earning capacities of the different properties, the quantity and quality of the ore reserves, the probabilities of more ore and its possible value; we have discussed the mining problems and the means of overcoming the difficulties arising from working at greater depth and the danger connected with caving ground; and we have taken into consideration the present and future equipment. Two of the members of your committee had all available reports and data before them at Washington, D. C. for several months before visiting the mines. They spent three weeks at the mines and ten days at San Francisco in investigations and deliberations. One of them, as a member of the firm of Smith & Perkins, visited Douglas

island in 1889 and brought about a change of ownership and initiated the plan of management since largely followed. The other member of the Committee has spent 16 years in the service of the companies and has an intimate knowledge of all their affairs.

The committee, with the facts, aid, and study given to the consideration of the problem, now urgently recommend a speedy consolidation of the three companies in as intimate and binding a way as possible. The legal method of working out the consolidation should be left to your able legal advisor, Judge Curtis H. Lindley.

The equitable basis for the consolidation we find to be 54% Alaska Treadwell, 34% Alaska United, and 12% Alaska Mexican.

The dominant necessity and advantage of immediate consolidation seem to us to be as under:

The arrangement of joint management without unification of boundaries or ownership has been worked with efficiency and fairness in the past, but it is not possible for this arrangement to take care of the future. In the past, the management has been able to preserve the equities and keep separate the ores of each property; this is becoming a more and more difficult problem with depth owing to the caving of pillars.

The recent development of the Treadwell, 700-Foot Claim, and Mexican mines has been disappointing, complex and interlacing; and the lower levels of these three mines as at present developed are not payable as a whole. However, the lower levels of the Ready Bullion are, as already stated, in a much more satisfactory condition.

There is no certainty that the trend of the gold-bearing dikes and of the barren dikes in the Treadwell, 700, and Mexican mines will continue in depth as at present; that is, while the orebodies show a tendency to unite in one great ore-chimney, we cannot predict its trend in depth. On the other hand, the history of the Ready Bullion, Mexican, 700, and Treadwell mines, with an output of \$62,797,459 from which \$21,337,651 in dividends has been paid, makes it imperative that all these mines should be explored and proved most exhaustively in depth.

The 2100-ft. level from the Central shaft is the lowest that has been fully developed and this has proved the existence of a great mass of low-grade ore, but only parts of it are profitable.

The 2300 ft. level from the Central shaft is only partly developed, and while the assays from development work thus far show ore that is close to the economic limit, a bore-hole run 272 ft. in the most promising part of the 700 mine gives an average assay-value of \$2.40, with several assays above \$9 per ton.

There is not sufficient certainty of the behavior of the orebodies in depth to justify any one of the companies in undertaking the burden of deeper development alone, inasmuch as it would cost over \$1,000,000 for additional equipment and exploration down to the 2700-ft. level.

The most conclusive results can be obtained most speedily and economically by seeking for more orebodies upon the lines laid down by Nature rather than upon artificial boundaries of ownership.

To join resources, interests, and hopes, each of the companies must have a fixed and definite interest in future discoveries. As the companies have experienced varying periods of good and ill fortune, it would have been a difficult problem to have selected any particular time as the most equitable for consolidation. However, as the situation now confronts us, the effort to consolidate should no longer be postponed; any technicalities, prejudices, or refinements of calculation should not be permitted to stand in the way of accepting immediate consolidation as necessary for the common good.

A further grave objection to, and danger from, the continuance of the present system of separate ownership is that should a change occur in the common control and management, conflicts and disputes might result that would be most dangerous and injurious to all of the com-

panies. should be suspended must be acted upon immediately, as the lives of their workmen must receive first consideration.

In reaching our decision, and in making our recommendations, we are quite aware that in the future the allotment of value may be found somewhat in error, but we believe that the basis that we have worked out and adopted is as fair and just as the present facts and disclosures will permit.

TIN ORE has recently been found in the extreme northern part of Lander county, Nevada, in an unnamed short range of hills 20 miles north of Battle Mountain, a town on the Southern Pacific railroad. What the substance was, however, remained unknown until a mining engineer who had been in Mexico happened to see it at Battle

SURFACE VIEW OF THE 700-FOOT MINE AND PART OF THE ISLAND.

panies, especially at this time when their critical condition calls for the utmost harmony and mutual support in the planning and conduct of their operations.

Another problem fraught with most serious consequences has also to be faced jointly, namely the caving in the mines, connected with the fact that the workings are largely under the sea. The very strength of the 'greenstone' hanging wall, which has been a factor of safety in the past, may be a menace in the future for if it should give way, it may be in the form of extensive slips and slides rather than the domical caving normal to softer or weaker rock structures.

The fact that there has been no subsidence in the surface debris of the 'glory-hole' during the past year, and that the dip of the orebody has flattened below the 1450-ft. level, while reserves of broken ore have been greatly drawn upon during the past three years, intensifies the seriousness of the problem. The evidence of future disturbance may remain constant for a long period or it may change rapidly from day to day.

The mine superintendent and the general superintendent, both of whom have a thorough knowledge of past cavings, are on the spot to watch daily indications. Their judgment as to when the drawing of ore reserves

Mountain and recognized it as 'wood tin,' a name given to that form of the natural oxide of tin that is characterized by a concentric banding resembling the annual growth in rings of wood. Search was immediately made for the bed-rock source of the ore, which has already been found at several places in a belt two miles long. These occurrences were recently examined by Adolph Knopf, of the U. S. Geological Survey. The ore occurs in narrow veinlets in rhyolite lavas, which were erupted in middle Tertiary time. In places the veinlets are sufficiently numerous to form low-grade lodes, but because of the small development so far done not much is known as to the size, extent, and richness of these lodes. Indications of the stronger lodes, taken in connection with their geology, are, in the opinion of Government geologists, such as to warrant further exploration.

ORE OUTPUT of the World in 1915 totaled 426,892,673 bbl., equal to 57,298,786 metric tons. The United States contributed 65.85%; Russia, 16.06%; Mexico, 7.71%; Dutch East Indies, 2.9%; Roumania, 2.82%; India, 1.73%; and Galacia, 0.98%. The 1915 yield was an increase of 7%. Since 1857 the grand total is 6,017,457,366 bbl., the United States producing 60.1%.

Formation of Nitrate Deposits

Nitrate deposits of Chile are found in the Tamarugal pampa, as the great flat desert is called. The pampa is bounded on the east by the western range of the Andes, and on the west by the coast range. It is a country characterized by an almost complete absence of rainfall. Winds that blow across the continent of South America from the east are laden with moisture. As they reach the eastern side of the Andes they are deflected upward. This movement causes a rapid cooling of the air, due to the lower temperatures prevailing at higher altitudes, and to the decrease in atmospheric pressure. Consequently, these moisture-laden air-currents precipitate their moisture most copiously on the eastern Andean slopes, and reach the western side of the mountains practically devoid of moisture. Instead of causing rainfall in the pampa country, these winds evaporate with extreme avidity whatever moisture they may come in contact with.

Almost equally dry are the winds that blow across the pampa from the Pacific Ocean. A short distance off the west coast of South America is a cold northerly current, known as the Humboldt, that acts as unfavorably on the climate of that coast as does the Gulf Stream favorably on the climate of the Atlantic coast of the United States. The prevailing winds along this west coast are the westerly winds coming in from the sea. As they cross the zone of cold water of the Humboldt current, they are chilled and lose most of their water-content. Then on reaching the coast, and being warmed up again, they are deficient in moisture and also have a great evaporating capacity.

Hence, whether it is the prevailing westerly winds or the occasional winds that sweep across the pampa from the Andes on the east that are blowing, the air over the pampa is nearly always extremely dry and evaporates water rather than precipitates it. These atmospheric conditions have made the pampa a desert in the strictest sense of the word. We speak of deserts in the Great Basin region of the western United States, but there one does see an occasional clump of sagebrush, or patch of greasewood, or at least a few scattered cacti, whereas one can search in vain for the smallest evidence of living vegetation over many miles of the pampa.

A consideration of these extreme conditions of parched winds, cloudless sky, and hot tropical sun have resulted in great *salar*s, or salt-beds, and nitrate deposits. The pampa is a flat plain with a gentle westward slope away from the Andes toward the coast-hills. The site of the present pampa was once a large broad valley that has been filled up with gravel, sand, and silt, washed down largely from the summits and slopes of the Andes mountains that tower above it on the east side. In past ages rainfall was more abundant in these regions than now, and the water collected in numerous depressions in the surface of the pampa in the form of inland lakes. On account of the westward slope of the pampa the lakes

formed mostly along its western edge. The waters draining into the lakes carried with them the soluble salts leached out of and formed by the disintegration of the rocks of the surrounding country, and since they had no outlet they became more and more saline, just as in the case of Great Salt Lake and the Dead Sea. As aridity increased the lakes finally dried up, giving rise to the highly saline depressions in the pampa that are known in Spanish as *salar*s. These are characterized by an abundance of sodium chloride, or common salt, in the underlying soil, and the absence of nitrate. The nitrate occurs in the surrounding higher-lying ground.

The only waters circulating at the present time across the pampa are the underground waters which have a general direction of flow from the higher slopes of the

DRAG-LINE SCRAPER IN NITRATE REGION.

Andes, their feeding ground, westward under the pampa to the sea. The upper surface of ground-water level has approximately the shape of the surface of the earth above it, but with less accentuated relief. In other words, it is nearer the surface at the points of lowest elevation and farther from the surface under the highest points. Consequently the underground waters are nearest the surface underneath the *salar*s on the west side of the pampa.

One of the striking features of the pampa is the shallow depth at which ground-water is encountered. In even less arid regions than this ground-water usually lies at a depth of hundreds, and in some cases thousands of feet, whereas, in the nitrate fields, the depth of ground-water is measured in tens of feet. Still more remarkable is the fact that in the *salar* in question, where the salt is produced, ground-water lies at a depth of only 3 to 3½ feet. Joseph T. Singewald, Jr., and Benjamin Le Roy Miller in *Bulletin of Pan American Union*.

THE BOSTON CREEK GOLD DISTRICT of Ontario has just been reported on by A. G. Burrows and P. E. Hopkins of the Bureau of Mines. The area is 45 miles northwest of Cobalt. The T. & N. O. railway traverses the field. The elevation is from 700 to 1050 ft. Principal rocks are greenstones with some volcanic fragmental rocks, the former containing gold-bearing veins. The deepest shaft is down 135 ft.

Comparison of Stopping Methods at Calumet & Arizona Mine

By Philip D. Wilson^{*}

INTRODUCTION. *The mines of the Calumet & Arizona company are near Bisbee, Arizona. The ore is found as irregular masses in limestone near porphyry or along fracture-zones many hundred feet from the intrusive. In one place the ore has a vertical dimension of 900 ft.; other orebodies are over 200 ft. but many are only 30 ft. thick. Several methods of mining are employed; they will be briefly compared.

SQUARE-SET STOPPING. The square-set system is the most flexible of any used, and where the orebody is irregular, with included blocks of waste, it is the most satisfactory. The waste can be left behind as a portion of the filling, and where the mining of too large a section is not attempted and the filling is kept within a reasonable distance of the back, it is as safe as any method. The cost of mining, including labor, powder, timber, carbide, and air, ranges from 80 cents per ton in sulphide ore to \$1 or even \$1.30 in oxidized ore. Where the ground is heavy, additional timber as bulkheads and double sets increases the cost, and in sulphide ore the excessive timber makes the risk of fire an important consideration. In a normal square-set stope the item of timber (laid down at the mine for \$17.50 per thousand) is 25% of the total cost of mining.

RECOVERING SQUARE-SET TIMBERS. The attempt to reduce expenses was made by M. W. Mitchell, foreman of one division of the mines, who devised a method for robbing a portion of the timber from a square-set stope during the process of filling. Approximately 50% of the timber can be recovered, and the cost is reduced by about 8%. The ground may be too heavy to risk removing the timbers, or the timber may be so badly damaged that it is not worth extracting. The method serves best where an orebody is mined in successive sections so that the recovered timber may be left in open sets at the edge of the stope and used when the adjacent section is being worked, as the cost of excessive handling reduces the saving to the vanishing point.

It is not feasible to recover timber from a stope over 50 ft. high. A gangway is maintained in the central row of sets on the sill-floor and chutes are built in the alternate sets on each side. Slides at appropriate places will deliver the broken ore to the chutes with a minimum of shoveling. When the ore has been extracted and the stope is ready for robbing, 6 by 6-in. braces are placed between the two diagonally opposite caps in the second and fourth rows of sets on the two floors above the sill. After the braces are put in place the caps in the second row are cut to permit of slipping-out the girts. When

these have been removed, it is a simple matter to remove the caps and the sill and first-floor posts. Waste is then introduced for filling until it reaches within a few inches of the second floor above the sill. As soon as the timber is removed, it is replaced by 'gob,' or waste, so that the walls of the stope are at all times amply supported. It is evident that by using this method in sev-

TIMBER BROKEN BY PRESSURE AT BISBEE, ARIZONA.

eral successive sections, only every third row of posts and caps is left behind in the 'gob,' while all the intermediate timbers are recovered. Success is due to the narrowness of the stopes, and the care in keeping the filling well up to the floor from which the timber is being taken.

SLICING SYSTEM. The next improvement in stopping was a slicing system, also devised by Mr. Mitchell. A block of ore broke from the back in a heavy sulphide stope, and in order to recover it, long stringers of timber were thrown across the top of the ore to support the back,

^{*}Abstract of paper to be read at the Arizona meeting of the American Institute of Mining Engineers in September.

and the ore mined from above by underhand stoping. The method is applicable to orebodies in which the hanging wall is flat and regular, and the lateral pressure not too great. Square sets may be used in mining irregular and outlying portions. There must be no large quantity of waste in the ore, for while it is possible to sort and leave some waste behind in the stope, the method loses its advantage if careful sorting has to be done.

A small sloping cut is made in every alternate set on the same side of each cross-cut for a loading-chute, but not on both sides of the same pillar, for if this is weakened, trouble is sure to ensue. The first slice is taken from raises over the whole top of the pillar, cutting it loose from the hanging wall. Where only one chute is used the broken ore fills the square sets until its normal angle of repose is reached, the remainder running from the chute by gravity. Stringers, 15 ft. long framed with 2-in. tenons, are thrown across the open slice between the caps of the topmost run of square sets and directly under the hanging wall with such blocking and lagging as is necessary to keep the stope safe and the timbers secure. The next slice is then taken across the top of the pillar. Drills set-up on columns between the stringers are used to make down-holes, pointed so that the ore is broken directly into the chutes. The slices are taken to within one floor of the sill, leaving one set of ore to be mined from below. A floor is then laid over the entire stope and 2-in. lagging is spiked vertically to the inside of both vertical runs of square sets, leaving the square sets open, when the stope has been filled for a set of chutes in each of the adjoining sections. If the ground is heavy, it is impracticable to leave the sets open, and they are lagged on the outside and filled with the rest of the stope. Upward of 50% of the stringers may be removed under favorable conditions.

The maximum height to which a section may be mined safely by this method is about 60 ft. The saving in labor, timber, and powder over the square-set system is obvious, but the main advantages are the rapidity with which the ore may be mined and the increased tonnage per man. While 5 or 6 tons per man is considered creditable in a square-set stope, it is not extraordinary in mining the pillars as above described to mine three or four times as much and in soft ground a yield as high as 50 tons per man per shift has been attained. The saving in the cost of stoping amounts to 20 or 30% of that of the square-set system.

TOP-SLICE CAVING. It was decided that the top-slice caving method as used on the Minnesota iron range, at Cananea, and elsewhere, might be applied to a large body of oxidized ore in which heavy and swelling ground made the cost of square-sets excessive. An inclined top-slice caving method was devised by Mr. Mitchell; this reduces the handling of ore in the stope, incidental to ordinary top-slicing, to a minimum. The method is applicable to the same conditions as ordinary top-slicing, that is, to uniform ground too heavy for economical square-set stoping and caving readily, but kept under control. There should be reasonable assurance that no

ore is left unextracted above the body to be caved, as the subsequent mining of this would be attended by many difficulties. In common with ordinary top-slicing, ventilation is poor in the stopes. Some ore is sacrificed in the process even under the most satisfactory conditions. The orebody is laid out in 45-ft. sections that may be mined for the width of the ore to a maximum of 80 ft. Permanent six-post raises are driven, preferably in waste at the edge of the ore, to a height equal to the top of the orebody. One compartment is used as a chute, the other for passing timber and men. Parallel rows of square sets are carried the width of the ore on the three floors directly beneath the hanging wall. A pillar 40 ft. wide is mined by horizontal slices from the top downward, one-half from either side simultaneously, and the back allowed to cave as stoping progresses. The first cut is taken from both sides simultaneously across the pillar at the end of the ore and is supported by standard square sets. As the slice retreats toward the main drift, the rows of square-set posts first erected are shot and the back caved, leaving at least two open sets between the working-face and the caved ground. To prevent the square sets being crushed by the weight of caved ground, small bulkheads are built under the lower caps of this floor resting upon the angle-timbers. The posts are then cut at points directly under the angles, thus transferring the weight from the square sets below to the solid ground in the pillar. When the upper slice has proceeded far enough from the extremity of the section so that the ground first caved is solid, preparations may be begun for the second slice. After the preliminary cut has been made, the major portion of the ore is 'slabbed' directly into the chute-sets, leaving one-third to one-fifth to be shoveled. It has been found that the maximum thickness of slice that can be safely carried in these mines is 10½ ft. and slices of this thickness are not attempted until the fourth slice is taken and the caving mat is under perfect control. If waste is encountered in the ore, it is feasible to sort and leave it behind to become incorporated with the caved ground and timber mat, but like the method last described the system loses most of its advantage where careful sorting is necessary. A 10% reduction in cost is gained over ordinary top-slicing. The labor cost is cut about 15% and the item of powder is reduced. The ore may be mined rapidly and safely in the heaviest kind of ground. An output of about 10 tons per man per shift or a total of about 125 tons per day can be maintained from each section.

CUT-AND-FILL SYSTEM. A cut-and-fill method was devised by Oscar Gilman; this permits of a minimum of timber, low cost, flexibility, and tonnage. The method may be used wherever the ore and country-rock are strong and solid, and while the width of each section is limited to 40 ft., the length and height of stopes are limited only by the extent of the ore. Cross-cuts are driven at 10 ft. intervals, and a cutting-out stope is started by enlarging the cross-cut with stoper-drills. When it has reached a height of 8 or 9 ft. above the rail, hitches are cut in the walls and temporary stringers are

thrown across the cross-cut at 5-ft. intervals, 5 ft. above the rail. Flooring is laid upon the stringers so that ore may be loaded directly into cars.

During this preliminary preparation, at about the centre of each section a raise has been started to connect ultimately with the level above, and to be used for timber and filling. When the 10-ft. limit has been reached, waste is admitted and forms a cone extending out toward the edges of the stope. The back may be supported in any weak spots while the next slice is being taken by temporary stulls or bulkheads resting upon the waste. As the chutes under this fill are covered they are abandoned and the ore as broken runs upon the sloping

each stope on the sill-floor is left to be mined from below. The cost under this system is low. It will average about 50c. per ton. Although slightly more expensive, than the old shrinkage method, the factor of safety more

than compensates for the small increase of cost over the more hazardous system. The ventilation is good and the efficiency of the men high. An average yield of 12 tons per man per shift can be maintained under normal conditions. The daily output of each section will average

floor and is drawn from the chutes still open at either end of the waste.

Carrying a stope between two filled sections is at best an uncertain operation and the risk may be avoided entirely by taking the sections in succession as described. The ridge of ore 35 ft. wide and 14 ft. high between

100 tons per day and may be crowded to 150 or even 200 tons.

SUMMARY. The cut-and-fill system is easily the cheapest and most satisfactory in every way where conditions are favorable. The item of timber, usually a large one,

COMPARATIVE STOPING COSTS								
Method and Conditions	Labor	Explosives	Timber	Candles or Carbide	Air	Other Supplies	Total	
Square-set, oxidized ore, heavy ground.....	\$0.73	\$0.06	\$0.34	\$0.01	\$0.12	\$0.01	\$1.30

Cut-and-fill, old method, sulphide ore, good ground.....	0.22	0.01	0.04	0.01	0.01	0.01	0.46	

is much reduced and the risk of fire is virtually eliminated. While any large 'horse' in the ore may be kept separate and left in the fill, any attempt at close sorting is inadvisable. As in the case of the slicing system, if the ore is fairly clean the greatest ultimate economy will be gained by mining it all as it comes, without attempting to sort. The consequent low cost obtained by mining a large tonnage rapidly will more than off-set the increased cost of handling and treating a slightly lower-grade ore. In neither system can the grade of ore be controlled as closely as in the square-set or top-slice caving methods. Where the ore is irregular or badly mixed with waste, the square-set method is the best. If the stope is in good condition a considerable proportion of the timbers may be extracted safely as it is being filled.

For a heavy uniform orebody the inclined top-slice caving system is recommended. While it still retains some of the disadvantages of the old-fashioned top-slice, it is in many ways an improvement over the older method. The principal advantages are the saving in labor and powder, and the rapidity with which the ore may be mined. The unfavorable features are those of all top-slice caving methods: the almost inevitable sacrifice of some of the ore, narrow work, poor ventilation in the stopes, and the fact that the ground above is so badly broken as to render the expense of future work on upper levels so great as to be almost prohibitive. The slicing system finds its chief application to fairly regular orebodies in not too heavy ground. Under favorable conditions the cost is lower when using this method than when using any of the others, with the exception of the cut-and-fill method. The saving in labor and timber is appreciable over square-set stoping and the cycle of preparing, mining, filling, and abandoning a section is normally a short one. This feature, in addition to permitting a large daily output, reduces the repair cost incidental to keeping a section of the country open over a long period. The introduction of these methods has effected a large saving to the Calumet & Arizona Co. during the past few years without endangering the safety of the men or of the mines.

Electric Pumps

Pumps driven by electricity are either of the reciprocating type or the centrifugal type. Generally speaking, a reciprocating pump driven by an induction motor is suited to pump a regular amount of water against a head that may be varied at pleasure. With a centrifugal pump, on the contrary, the quantity of water can be regulated, but the head cannot be materially changed without making structural alterations in the pump. A reciprocating pump is adapted for work in mines where the flow of water is steady, and where it is a convenience to be able to transfer the pump to different levels as the mine is deepened. The centrifugal pump cannot be shifted to different levels without impairing the efficiency, but it can take care of a varying flow of water

as a consequence of the change of seasons. An advantage of the centrifugal type is that the quantity of water pumped can be regulated within comparatively wide limits, with but slight variations in the efficiency, by simply opening and closing a valve on either the suction or the discharge-pipe. A reciprocating pump, on the other hand, must be run at constant speed, unless the speed of the motor can be varied, as with a direct-current motor. But a centrifugal pump may be altered for work on different levels by changing either the number or the diameter of the impellers. In smaller sizes a centrifugal pump is inefficient, but the efficiency increases with the size. Pumps of a capacity of 600 to 1200 gal. per minute can be easily maintained at an efficiency of 55 to 65%.

At a Michigan mine 900 ft. deep, where the flow is 30 to 40 gal. per minute, there is a motor-driven horizontal plunger-pump of a capacity of 125 gal. per minute. On Sundays and holidays the pump can be operated from surface, the high and low-water marks in the sump being furnished with an electric device for signaling to the hoist-house. At another Michigan mine 1150 ft. deep, two motor-driven plunger-pumps are employed. One is triplex and has a rated capacity of 95 gal. per minute, the other is duplex and has a rated capacity of 125 gal. The flow at this place averages 50 gal. per minute, occasionally reaching a maximum of 150 gallons.

Figures on the cost for maintenance of centrifugal and triple-expansion steam-pumps show a decided advantage for the centrifugal type. The following figures from a Michigan mine for eight pumps, four of each type, during one year:

	Centrifugal	Steam
Shop labor	\$717	\$760
Labor on pumps	690	590
Supplies	503	2021
	\$1910	\$3371

It is seen that the labor cost was about the same for each, but that the steam-pumps had a greater expense for supplies, mostly for packing for the water-end. The centrifugal pumps mentioned had motors with wound rotors and a device for short-circuiting the secondary current and relieving the brushes from wear by lifting them from the rings. These pumps were rated at 900 gal. per minute each. The flow of water increased to 1100 gal. This was too much for one pump and not enough for two, so it was necessary to start and stop one pump frequently. Later it was found that by increasing the speed of the generator in the hydro-electric power-house from 60 to 62½ cycles per second, each pump could handle 1200 to 1300 gal. per minute. But this overloaded the motors and, after running some time, it was found that the insulation had been baked until it was brittle. This made trouble when it became necessary to repair the windings. A drop in efficiency will also overload the motor, so that it is well to provide centrifugal pumps with motors of a size larger than for the normal head and quantity.

Mining in Arizona

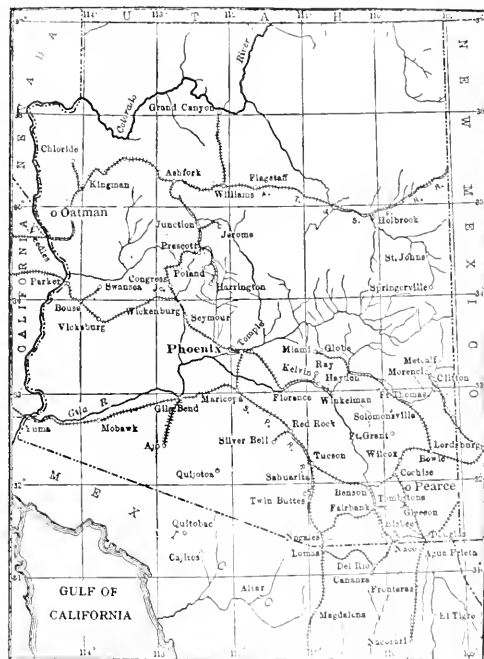

By Charles F. Willis

Mines and smelters in Arizona have been working at such high pressure this year that they are making record outputs of all metals. If they continue to work at the present rate for the remainder of the year they will produce over 600,000,000 lb. of copper, against 450,000,000 lb. in 1915. A corresponding increase in the output of the precious metals, and in lead and zinc, combined with higher prices, will make the total value of the current year nearly double that for 1915, which was about \$88,000,000. Aside from effort to take advantage of what was an unusually active market, several factors have aided this increase, such as resumption of the Clifton-Morenci mines in January. The International smelter, which reduces Inspiration concentrate, contributes the greatest part of the increase, as this plant is supplying about 25% of the total copper. Marked increases and improvements were made at the United Verde, Miami, Calumet & Arizona, and Old Dominion mines. The Saseo plant in Pima county was again blown-in. The railroad to Ajo was completed, and work has been started at the New Cornelia on a 400-ton leaching plant. There is great activity in the production of gold, especially in Mohave county, and the high price of zinc has stimulated production at the Tennessee, Union Basin, and Kingman zinc mines, which are in the same region.

Announcement that the U. S. Bureau of Mines had authorized a mining experiment station at the University of Arizona, is a step forward. Permanent progress of the State is dependent on mining. Over 25% of the males here are employed at mines. It was not unexpected that Tucson would be chosen as the site of one of the first three stations authorized, for while the city is not the geometrical centre of the State, it is in almost every other way. Tucson is on two main railroads, and has other lines branching from it. It is the centre of the State's educational activities, of the State Bureau of Mines, of the State University, the centre of population, the centre of the State's copper production, and the centre of money distribution. It is connected directly with all of the largest copper centres of Arizona save Jerome. Although the U. S. Bureau of Mines has an independent personnel, its presence is of great advantage to the students of the University of Arizona College of Mines. The influence of noted investigators, the use and observation of machinery that would not otherwise be available, an insight into methods of research of great problems, all of these are of benefit to the student. This, coupled with the fact that the ground has already been broken for a new mining and engineering building of the University, is important. The last Legislature appropriated \$75,000 for a new building, contingent on the University authorities raising an equal amount. Through the generosity of the mining companies, who contributed in proportion to their copper-output, \$100,000 has been

raised, and the plans for the building are actually under way.

It seems to be generally considered that a State advancing in metal output as is Arizona, can have but few unsolved problems; an analysis of the situation will show that this is not so. Over 95% of the copper produced in the State is from 13 companies, out of 400 producers. Although mining contributes both directly and indirectly about 66% of the State's taxes, over 90% of this amount is paid by these 13 companies, practically bearing the burden for the entire State. There are thousands of mines here waiting for suitable treatment

MAP OF ARIZONA.

methods. At present, with no facilities for metallurgical research, the only hope of the smaller companies having such problems is to sell to the larger corporations having the capital to carry on research. This is proved by many recent changes of ownership. The Calumet & Arizona spent a large sum in devising a process for its Ajo ores, although the mine there is one of the oldest in the State. Lead, zinc, and molybdenum ores are others requiring attention.

Probably the greatest discussion of the past month has been on the proposed copper tax. This would hit Arizona hard, causing the operators to pay approximately \$1,000,000. Arguments have not been against a tax, but rather on the unfairness of singling out the copper industry for taxation. When the price of copper reaches a normal level, such a tax would be extremely burdensome, in many cases prohibitive.

The Parker district offers good opportunities to mining men. The Manning & Roeder property was acquired last week by J. L. Melver and Geo. W. Long, the men who discovered and developed the United Eastern gold mine at Oatman. Associated with Melver and Long in the purchase are W. K. Ridenour of the Telluride Mining & Development Co., and A. L. Kreiss. The property consists of 23 claims, 8 miles north of Parker on the west side of the Colorado river. Over 3000 ft. of development has been done and extensive bodies of copper ore have been opened. The purchase price is \$300,000, with a substantial cash payment, the balance to be paid in installments extending over two years.

By a first payment of several thousand dollars the sale of the 50 copper claims of C. J. McNulty and M. McBride on Copper creek, 10 miles south-west of Prescott, has been consummated, and the group is now in the hands of the Daly-Crawford-Lewisohn syndicate. It is stated that the consideration was over \$300,000. The ground has been thoroughly prospected, the original owner, McNulty, having devoted more than 15 years to this work.

The largest mining deal ever closed in the Walker district, south of Prescott, as well as in this field generally, is that by which the Sheldon Mining Co. succeeds to the holdings of the Major Mining & Milling Co., in which the cash has been paid and the titles cleared. All conflicting interests of the estate of H. T. Andrews, deceased, Stucky brothers, the Metals Mining Co., the Empire Mining Co. and the Major Mining & Milling Co. have been merged with the Sheldon, embracing a group of nine gold-copper mines of attractive rating. With this transaction complete, operations will soon begin on a large scale. It is probable that the Eureka and Sheldon holdings will be the base of operations. John F. Pell, of Newark, New Jersey, is to head the Sheldon as president. Negotiations to effect this important merger have been under consideration for several months. Some of the oldest and best known of pioneer gold mines in this county that had lain idle for years are now assured of becoming active, and probably highly productive.

Rapid progress is being made at the New Cornelia company's leaching-plant at Ajo. After various delays construction progress is now satisfactory. The leaching vats are 88 ft. square. The power-house is 160 ft. square, and the electrolytic tower-house 160 by 280 ft. To feed the cement-mixers and keep the concrete work going, a temporary crusher is at work continuously, providing 350 tons of crushed rock per day.

After lying idle, water-logged, and caved for years, the old Harqua Hala Bonanza gold mine has come to life with the opening of another rich shoot in new ground north of the old workings-shaft. The vein widens with depth. It might be assumed that a mine which has produced \$1,000,000 would be a deep one, yet this is not so. It was worked in the early days to a depth of 100 ft.; levels were driven at intervals of 50 ft., and some of them for a considerable length. But the deeper ore is still undisturbed, save for the new work. The ore also carries copper. The 10 stamp mill is crushing ore from the up-

per levels. After the winze has been sunk 200 ft., and the ground further explored from it, a three-compartment vertical shaft will be sunk. The mill will also be greatly improved.

Another suit, further complicating the already tangled affairs of the Hull Copper Co., was filed recently at Prescott. The names of Wm. H. Kemp, G. O. Bowman, Benj. P. Walton, Andres B. Tarbett, and John H. Page appear as plaintiffs; the Hull Copper Co., Geo. W. Hull, Mrs. Mary A. Hull, S. F. Denison, Will L. Clark, Chas. W. Clark, W. A. Clark, and the United Verde Copper Co. are named as defendants. One of the principal allegations of the plaintiffs is that a number of shares have been wrongfully issued to Hull and his wife. Other complaints petition for a disclosure of all facts in connection with the recent deal for the transfer of Hull's controlling interest in the Hull Copper Co. to the Clark interests. A temporary injunction preventing this is asked. The history of the Hull litigation dates back several years. All the company's funds were exhausted and Hull, it is alleged, personally advanced large sums for the continuation of development. He eventually filed suit for an accounting. The hope is expressed that the new litigation may result in some Court action that will make possible the transfer of all the Hull ground to the United Verde, and its development by that company. It is certain, however, that much time must pass before this is brought about.

ON ACCOUNT of the present high price of mercury used in the manufacture of mercury fulminate, detonators have greatly advanced in price. Manufacturers are seeking a substitute to partly replace the fulminate. By the use of a suitable base charge and of a fulminate-chlorate as a primer in the reinforced detonator, about one-half as much fulminate is required for a cap of given strength. Commercial blasting-caps have been manufactured containing both TNT (trinitrotoluene) and tetryl as the base charge. About 0.40 gram of base charge and 0.32 gram of 90:10 fulminate-chlorate primer make a cap of the No. 6 grade. It is important to use as a factor of safety about 50% excess primer above the minimum quantity required for complete detonation of the base charge. It is also important to use a base charge not too insensitive to slightly moist fulminate. Any explosive proposed for use as a base charge should be thoroughly tested to meet any possible conditions of treatment or storage to which the blasting-caps are likely to be exposed in practical work, for the failure of a single cap may be a serious matter. On account of its insensitiveness to slightly moist fulminate, TNT has proved an unsatisfactory base charge.—Abstract from Technical Paper 145 of U. S. Bureau of Mines, by G. B. Taylor and W. C. Cope, entitled "Sensitiveness to Detonation of Trinitrotoluene and Tetranitromethylanilin."

NITRO-GLYCERIN of 50% strength is now selling at \$19.50 per 100 lb., or \$390 per ton.

Concentrates

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

To CONVERT specific gravity to Baumé gravity, divide 140 by specific gravity and deduct 130. The result is the Baumé gravity (approximate). To convert Baumé gravity to specific gravity, add 130 to Baumé gravity and divide into 140, giving specific gravity (approximate). Specific gravity multiplied by 8.331 gives pounds per gallon.

THE DANGEROUS GAS CO should not result from the explosion of a modern high explosive. The results of blasting should be CO and H₂O, providing the explosive is properly compounded and detonated. It has been said that the carbon contained in the paper wrappers of dynamite sometimes makes CO gas. As little as 0.25% of CO in the air may affect a miner, while 7 or 8% of CO₂ (called 'choke damp') is necessary to cause distress.

IN BLASTING, the more nearly the charge of explosive is adjusted exactly to the burden of rock, the more complete should be the explosion and the less should be the fume. The pressure of the explosion is greatest when a charge is carefully adjusted to the burden, the thermodynamic changes being interdependent. Over-charging of holes in blasting is customary, in order to ensure a successful shot.

THE HIGHEST habitation in the world is stated to be in Peru. Professor Isaiah Bowman reports that he crossed the Andes by the passes between Antabamba and Cotahinasi, and at 17,100 ft. altitude saw a thatched stone hut that sheltered a family of five. These natives were apparently quite healthy, and "three rosy-cheeked children almost as fat as the sheep about them were playing with balls of wool." A man accustomed to low altitudes could not live at so high an altitude without suffering ill-health.

A GOLD TRUST-FUND is proposed for simplifying commercial settlements between the different North and South American countries. This would save unnecessary transfer of gold in adjustment of balances. A unit of money equal to one-fifth of the American gold dollar was approved at a recent conference in Buenos Aires. If adopted by the various countries, this would provide a uniform basis of transaction among all the American nations. It will also afford a standard likely to be adopted for gold coinage by South American countries when they find themselves able to employ a gold basis.

COMPRESSED AIR can be utilized in a variety of ways around an industrial plant. Not only the mechanical force of the escaping jet is used, but it is an efficient drier, and, when equipped with spray, a moistener. For cleaning out-of-the-way nooks nothing can equal it.

It agitates cyanide or flotation liquids, ventilates mine workings, and blows factory whistles. It is clean, and when it has done its work is in nobody's way. Air-pressure is one of the best ways of quickly and thoroughly forcing the water out of boiler-tubes, as well as testing for leaks in pipes or boilers.

ELECTRIC HAULAGE underground is well liked at large mines where the tramping can be concentrated on a few levels, as in the extraction of large mass deposits of copper, iron, or low-grade gold ore. In mines where the tramping is scattered on many levels, as in the Michigan copper mines, or in mining narrow lodes of high-grade ore, electric haulage is not so well adapted. The cost of maintenance of underground electric traction in a large mine is likely to be about 15c. per ton-mile. Of this, 2c. would be for power, 5c. for maintenance of track, 4c. for maintenance of trolley, and 3c. for maintenance of locomotives. Similar costs were found necessary in the Copper Queen mines at Bisbee.

PRICES of lumber during 1915 are given in a bulletin of the U. S. Department of Agriculture. The most expensive woods in a list of 27 were cypress, yellow poplar, hickory, and ash, all worth between \$20 and \$23.50 per 1000 ft. Of the soft woods, white pine was \$18, hemlock \$13, spruce \$16.50, redwood \$13.50, cedar \$15.50, and tamarack \$11. Southern yellow pine, of which a great quantity was cut, constituting 30% of the total, was \$12.50. Douglas fir, which contributed 10% of the country's cut for the year, was \$10.50. Of the hardwoods, oak sold at \$19 per thousand, maple at \$15, birch at \$16.50, and cottonwood at \$17.50. Oak, white pine, and hemlock are the only varieties other than yellow pine and Douglas fir, of which over 2,000,000,000 bd. ft. was cut.

THE SLACK-CABLE SYSTEM for removal of ore from underground is being tried at the Quick Seven zinc mine, in the Joplin district of Missouri. The excavating outfit consists of a mast or gin-pole, supporting a track-cable upon which runs the bucket, and the engine necessary to operate the bucket. The engine has two drums, one of which, by a direct pull, loads and hauls the bucket; the other, by means of a set of double blocks, tightens the track-cable in order to raise the bucket off the ground. The system is installed at the side of a large cave-in at the mine. There is a 115-ft. face of ore, extending from a depth of 160 ft. to within 15 ft. of the surface. The ore averages 17% zinc. One great advantage of the slack-cable system is that it works equally well in dry ground or in water. In other words, if the cave in at the Quick Seven were completely filled with water, the bucket could operate at nearly the same efficiency as if it were drained. The upper 15 ft. is of sand and clay. This will be washed down and disposed of hydraulically, thus leaving the orebody exposed to the direct action of the bucket. One Morris and one Cameron sand-pump have been installed for this work.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

WASHINGTON, D. C.

A SESSION WITHOUT VALUE TO MINING

This session of Congress is about to close without having done anything for mining, save what is involved in the general appropriation bills, but these have included no new legislation bearing on the industry. The bill to create a commission to codify the mining laws has failed in final action, and is considered dead for this session, inclusive of the short session beginning in December. While considerable enthusiasm was manifested at the beginning by members of the House for the passage of such legislation, opposition developed in the House Committee on Mining, which decided that if there was to be any codification at all, it should be done by the Committee itself. The bill that passed the Senate was side-tracked, similar treatment being given the bill of Representative Foster of Illinois. The whole Mining Committee has now adjourned *sine die* for the current session, without taking action, and all that has been held out is hope that something would be done at the short session. This, however, will be crowded with business, particularly in anticipation to the inauguration of the new President. What has vexed mining men particularly is, that while there has been general sentiment in Congress favoring codification of the mining laws, legislation should be held up by a few men, one of the most influential being James Wickersham, delegate from Alaska.

A final measure of interest to the West has been the passing, by the House, of the bill to authorize the Secretary of the Interior to lease for production of oil and gas ceded lands of the Shoshone or Wind River Indian Reservation in Wyoming. The act follows the lines of usual leasing bills. The Senate has yet to act on it.

HUMBOLDT, ARIZONA

NOTES ON IMPORTANT MINES OF THE DISTRICT.

The Stoddard and Copper Queen properties, 6 miles from Mayer, are erecting a joint mill of 100 tons' capacity. Each mine is about 1000 ft. from the mill-site, and the ore will be hand-trammed from them on a slight down-grade to the mine ore-bins. The two trams arrive at the bin with a difference in elevation of 8 ft. The mine ore-bin is flat-bottomed with two compartments, having provision for dumping the ore from either mine in either compartment. The run-of-mine ore will be taken from the bin by belt-conveyor to a Gates crusher. The topography of the country necessitated the digging of a pit for the crusher-discharge, which is then conveyed to the mill-bin by an inclined belt-conveyor. The mill-bin has a sloping bottom and holds 100 tons. A Marx mill in closed-circuit with a Dorr duplex classifier prepares the ore for the Gahl flotation machine. This consists of a 16-cell rougher, and a 6-cell cleaner, a diaphragm-pump being used to elevate concentrate from the rougher to the cleaner. All flotation tailing flows by gravity to three double-deck Deister tables, the tailing from which go to waste. Concentrate is dewatered in a Dorr thickener and 2 Oliver filters. Instead of a concentrate-bin, a long wide chute will be used to deliver the concentrate by gravity from the filters to trucks for haulage to Mayer, the nearest shipping point. The building is of wooden-frame construction with corrugated-iron walls and roof. It is expected that the plant will be ready for operation within a month,

possibly sooner. It was designed by Kenyon Burch. The Gahl flotation machines are the same as those devised at the Inspiration, consisting of air agitation exclusively. The ore contains 3% copper.

The Big Ledge Development Co., owning the Henrietta and Butternut gold-copper mines near Poland Junction, has bought the old Treadwell smelter at Mayer, and the Hackberry mine near-by. The company proposes to re-model the smelter along modern lines, using the Hackberry ore as basic flux for its own highly silicious ores.

The Big Pine gold mine owners, 18 miles from Prescott in the Groom Creek district, have purchased the old Mascot mill at Crown King, and will use most of the machinery in the construction of a mill at their property. Crushing by rolls, and counter-current decantation will be the cyanidation treatment. Precipitation will be by zinc-dust. Mr. Dunning is general manager.

Two miles west of Humboldt is the Camp Anderson lead-silver mine. A mill is contemplated, using Huntington mills and gravity concentration. Development is opening a good vein.

The New Year is an old property in the Chaparral district, 5 miles from Humboldt, recently re-opened by Prescott and Phoenix capital, under the superintendence of Claude Ferguson. The shaft was re-opened and thoroughly re-timbered to a depth of 200 ft. Operations were then suspended until two weeks ago, when a small crew commenced on development. One drift will be driven on two shifts, and another on day shift only. The shaft is inclined at about 70°; water and waste is raised and supplies lowered in a torpedo bucket, using a 15-hp. Fairbanks-Morse electric hoist, which has given good service for that purpose.

At the Consolidated Arizona the frame-work for a new temporary sample-mill is about completed. The old mill was burned on June 9. At present the company is handling only the Swansea ore and high-grade custom ores and concentrates, in addition to its own supply from the Blue Bell and De Soto mines. When the temporary mill is completed, the company will be able to handle its usual quota of custom ores. When the pressure of other work has slackened, the company proposes installing a modern change-room for its men. This will be a much needed and greatly appreciated improvement.

BUTTE, MONTANA

SILVER PRODUCTION—DYNAMITE FACTORY.—ELECTROLYTIC ZINC.

—SHAFT WORK AT BUTTE & SUPERIOR.—BUTTE-DULUTH AFFAIRS.

Few people realize the great quantity of silver recovered in this district. Anaconda produces 10,000,000 oz. yearly as a by-product from its copper. The Black Rock mine of the Butte & Superior yields 10,000 oz. daily. As the average price of silver for the first six months of this year has been 20% higher than that of last year, the increase has added considerably to the profits of all operating companies at Butte, also a good help to the smaller companies all over the State.

Construction work is being hurried on the Dul'ont powder-plant being built on a 1200-acre tract 8 miles west of Butte. Several buildings, to be used for storing powder, are complete, and have been surrounded with earth embankments to lessen

the danger from explosions. The factory proper is in a remote part of the ground, and the office buildings will be near the main road between Butte and Anaconda. Spur-lines have been constructed over the property from the main line of the Butte, Anaconda & Pacific road. Butte uses 6,000,000 lb. of dynamite per year. The nearest powder-plant is at DuPont, Washington, and as the freight-rate on explosives is high, a great saving will be effected by manufacturing the fracture nearer the point of consumption. Parts of Utah and Idaho will also be supplied from this plant. The factory will be completed late in December, and will manufacture dynamite and gelatine only. Nitric acid will be made from Chilean nitrate. Sulphuric acid will come from the Washoe plant at Anaconda. When working at normal capacity 150 men will be employed.

One unit of the Anaconda electrolytic-zinc plant at Great Falls has been started. Excellent progress has been made in construction, and the whole plant of 2000-ton capacity of ore per day is expected to be in operation by September 1. The Emma mine will supply most of the ore. Its shaft is in the heart of the residence district of Butte, and it will be difficult to construct a railroad spur to its ore-bins. The company had an option on the Czar and Travonia Fraction claims adjoining the Emma on the south-west, but allowed the option to lapse. The purchase price was \$300,000, and a payment of \$50,000 had been made. Why the property was not taken over is not known. The Emma vein extends through the Czar, and both claims could be easily worked through the Emma shaft.

The king-bolt on a loaded skip broke in the Black Rock shaft of the Butte & Superior, and the skip containing 5 tons of ore dropped from the 150 to the 1100-ft. level, where it lodged across the shaft, after having knocked out the timbers in all four compartments for a distance of 50 ft. A complete shut-down for 10 days was necessary while the shaft was repaired. The fact that a wreck of this kind usually puts all the compartments of a shaft out of commission was one reason why the management decided to sink separate shafts for hoisting ore and lowering timber. A typical Butte shaft is shown in Fig. 1. The new shafts are shown in Fig. 2 and 3. They are separated by a 50-ft. block of solid ground. The cage that lowers timber, transfers men, etc., is locally known as the 'chippy-cage.' Two compartments in the new shafts will be devoted to chippy-cages, to be run in counter-balance, effecting a great saving in power. By a combination of sinking from the surface to about 800 ft., and raising from the 1000, 1200, 1300, 1400, and 1500-ft. levels, the ore shaft was completed from the surface to 1500-ft. in 6 months. This is a new record for the Butte district. The average rate of sinking in hard granite, timbering as the work proceeds, is less than 100 ft. per month. The shafts will have separate stations on each level. The confusion that results from unloading timber on a station where ore is being dumped into a skip-chute will in this way be eliminated. Jackhammer-drills weighing about 40 lb. each were used in sinking. A round consisted of 24 to 30 6-ft. holes. All men working in the shaft were paid a bonus for speed, and with three machines the average drilling time per round was 2½ hours. Surveying was done under difficulties. On the surface the temperature ranged from zero to 40° below zero, the ground moved continually, several of the sights underground were short, and the timber-men had to be watched to get them to line-up the timbers accurately. Regulation shaft timbers were used in all the raises, and the connections were made with a maximum error of 2-in. The error is distributed among several sets, so that it is not noticeable in ordinary shaft operation.

The Butte-Duluth property has been leased to Alfred Frank and associates of Salt Lake City for 5 years. Repair work will be started immediately, and it is expected that the plant will be operating at full capacity by September 1. The property includes the Macaroni, Montgomery, Park, and Recorder claims, and parts of the Altona, Colleen Bawn, and Amazon. The ore was formerly mined in open-cuts with electric muck-

ing-shovels. Mining from open-cuts will be continued, and in addition the Montgomery shaft will be sunk deeper and much exploration work will be done. The mill will be enlarged to treat 500 tons of ore per day. The ore is crushed to 8-mesh with a gyratory, rolls, and Symons disc-crushers. It is then leached with sulphuric acid in Dorr classifiers, and the copper precipitated from the solution by electrolysis. It has been reported that a flotation plant will be installed and that leaching practice will be abandoned, because of the scarcity of sulphuric acid. Flotation does not seem practicable, as nearly 50% of the copper occurs as carbonates. The property was closed by

Fig. 1

Fig. 2

FIG. 1 IS A TYPICAL BUTTE SHAFT; FIG. 2 IS THE NEW CHIPPY SHAFT AT THE BUTTE & SUPERIOR, AND FIG. 3 IS THE NEW HOISTING SHAFT AT THE SAME MINE.

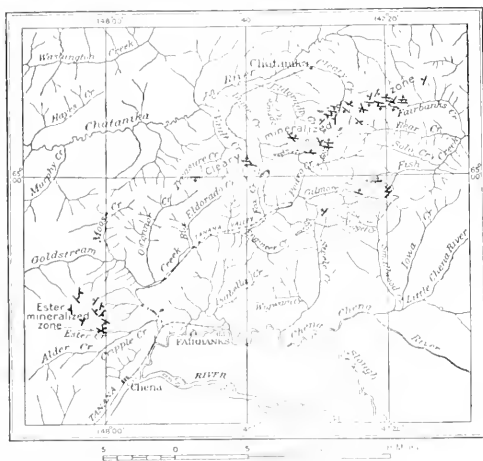

Court action brought by the Provident Securities Co. for non-payment of interest on bonds. A receiver was appointed. Claims for labor and lumber amounted to \$75,000. Until all the debts are liquidated the Butte-Duluth will be technically in the hands of the receiver. Under the terms of the lease the company will receive 50% of the proceeds after the cost of operation, construction, and the expense of receivership have been deducted. After February 1919, Mr. Frank agrees to pay the sum of at least \$7500 every three months. These payments will take care of the interest on the outstanding bonds of the company. Mr. Frank is well known in Butte. He was formerly consulting engineer for the Heinz interests. He took over the affairs of the Ohio Copper Co. in Utah under a similar receivership, and his success with that property was a big factor in influencing the bond-holders to give him a lease on the Butte-Duluth property.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

In Bulletin 649 of the U. S. Geological Survey, Alfred H. Brooks describes the antimony deposits of Alaska. Up to the recent drop in the price of the metal there had been many inquiries regarding occurrence of the ore in the Territory, and in 1915 the output was 833 tons of crude ore worth \$74,900. Stibnite has been found in 67 localities in Alaska, in nearly all the gold-bearing areas, but only a few deposits have been studied in detail, especially those in the Fairbanks district. Most of these occur in mica and quartz-schist. The country-rock of the lodes is sedimentary as a rule. The deposits show little oxidation. Fairbanks last year shipped 685 tons of 58% ore, from the Scraftord, Stibnite, Gilmer, and Chatham

SKETCH SHOWING DISTRIBUTION OF LODES AT FAIRBANKS.

Creek mines. Operations were on a small scale and chiefly by open-cuts. Details of other centres are given in the 64 pages comprising the publication.

ANCHORAGE. In the *Excavating Engineer* for August, L. T. Russell, briefly describes progress of the Alaskan railroad. The Anchorage division, in charge of Frederick Mears, is completed from Anchorage to Peters creek, about mile 135. The Fairbanks division is in charge of Thomas Riggs, while the Seward section is under W. C. Edes. The latter line is that of the Alaska Northern, acquired by purchase. Anchorage is the base of supplies for construction in both directions. Bucyrus steam shovels are in use along the line.

BRIERLY. The 3000-ton gas schooner *Kushikwim River* recently arrived here from Seattle with a full cargo, including a Union Construction Co., San Francisco, dredge for Candle creek. This was transhipped to the river steamer *Tana*. The spring clean-up on Candle was \$125,000. When the dredge commences the output will be much larger. Conditions in this region are much better, now that larger supplies are available.

ARIZONA

KINGMAN. Near here the Arizona-Butte Mines Co. is doing considerable work. Its Banner mine contains 38,000 tons of ore. To develop the veins in Stockton hill a long adit is to be driven, reaching a depth of 1500 ft. A compressor, engine, and drills have been ordered. The 200-ton mill is nearing completion. It includes a jaw-crusher, rolls, Huntington mill, screens, and concentrating tables, making lead and zinc concentrates. The tailing will eventually be floated.

OATMAN. The new custom mill will be ready to receive ore in about 30 days, the machinery now being overhauled. Water comes from the Big Jim mine.—At 400 ft. in the Big Jim 228 ft. of openings have been made; at 500 ft., 223 ft. of drifts.—At 750 ft. in the Boundary Cone the south drift has cut the vein 130 ft. from the shaft.

STREATOR. In the second quarter of 1916 the Magna Copper Co. produced 2,232,936 lb. of copper, with a profit of \$305,025. The price received was 24.16c. per lb., while costs were 10.47c. Respective figures for the previous term were 2,043,784 lb., \$270,201, 22.39c., and 9.13 cents.

CALIFORNIA

During the 22 years of the operation of the Workmen's Compensation, Insurance, and Safety Act, up to July 1916, there were filed with the Commission 2822 applications for adjustment of controversies over compensation claimed. Of this number of cases the Commission had, up to this date, decided 2407, and of these 94, or slightly less than 4%, had been appealed to the Supreme Court or District Courts of Appeal of this State. In all the others—2313—the decisions of the Commission were accepted by the parties as conclusive of the issues involved.

GOLDSTONE. The 200-ton mill of the Daggett Reduction Co. at Daggett is to be available for ore from the Goldstone district. This should aid lessees considerably.

GRASS VALLEY. More rich ore has been unearthed in the Golden Center mine. This company is also re-opening the Allison Ranch mine, at which unwatering is making steady progress.

OROVILLE. Local men, including P. Reicker, J. M. Chubbuck, G. C. Riley, and others have located 6000 ft. along the middle fork of the Feather river, which they will work by the diving system of mining.

On Slate creek 25 men are constructing a concrete restraining dam for Los Angeles people, who intend hydraulicking at Searles, St. Louis, Howland Flat, Port Wine, and other places.

PRYORVILLE. At the Montezuma mine the shaft is 1000 ft. deep, at which point cross-cutting is being done. Development is under way at 600, 500, and 800 ft. In charge of 25 men is R. Le Fontaine. This old mine is being re-opened by Plymouth Consolidated people.

PRYORVILLE. The following is the statement of output and expenditure for July at the Plymouth Consolidated:

Ore treated, tons,	10,500	Development charge, \$	7,214
Total value,	\$7,300	Surplus,	23,869
Working expenses,	96,217	Other expenditure,	5,256

(Special Correspondence.)—The Argonaut mill is nearing completion. The Kuhl company of Sutter Creek is sub-contractor, a Los Angeles firm being in charge of construction.

The new plant will be equipped with 60 stamps, replacing the 40-stamp mill now in use. The large concrete dam for storing tailing from the new mill is 40 ft. high at the lowest point and 400 ft. long, forming a basin that will hold the waste from this mill for many years, and eliminate present expense and inconvenience. N. S. Kelsey is superintendent of this well-known property, which is one of Amador county's best dividend-payers.

Owing to encountering a cave in the shaft it is said that the work of unwatering the old Eureka has not progressed so well during the past week. A point near the 500-ft. level has been reached, and all efforts are being made to catch up the cave. The plan is to install another pump when the 600-ft. level has been reached, but it is expected that more or less difficulty will be encountered from now on, as it is not expected that the mine could remain full of water for 30 years without causing damage to the shaft.

At the Bunker Hill mill near Amador City a new building, 50 by 80 ft., is to be erected to house new rolls and concentrators. This mine is paying well, but the management realizes the benefits to be derived from modern methods of treatment.

Sutter Creek, August 16.

WOODY. The Weringer Mines Co. has 2 years' ore ready to extract. The 100-ton flotation plant is expected to be in operation within 90 days. High-grade chalcocite was encountered in the 200-ft. level cross-cut. About one car per week of high-grade sulphide is being extracted for shipment. One lot of rich carbonate from the upper levels will be sent to Selby this week. The winze at 200 ft. is down 12 ft. in 4% chalcopyrite, suitable for milling.

COLORADO

LEADVILLE. Exploration of the Down Town property is to begin at once, now that the water in the Penrose shaft is under control.—At the Wolfstone shaft the water is below 1000 ft., leaving 100 ft. to be drained.—For the Mikado shaft on Iron Hill the Colorado Power Co. is constructing two transmission-lines.

MONTEZUMA. At the St. John mine there is 6000 tons of stope-filling on the surface, ready for treatment. This is part of 30,000 tons rendered available by development. A profit of \$2 per ton is expected from this. A stope 400 ft. long is ready for extraction.

OURAY. The Revenue tunnel of the St. John company is completely repaired. The re-modeled mill is soon to be ready, with a capacity of 3000 tons monthly. Copper recoverable from old mill and power-plant is valued at \$25,000.

TELLURIDE. In July the Tomboy Gold Mines made a profit of \$29,240 from 13,000 tons of ore, yielding \$93,500.

IDaho

SALMON. Ten of the 15 stamps at the A. D. M. & R. mill at Gibbonsville are to resume crushing shortly, in charge of E. E. Edwards. A good deal of ore is ready for the plant. — Near the old town of Yellow Jacket a hydraulic hoist is being installed by Burkhardt & Son. Near-by, H. De Prew proposes to add 30 stamps to the Yellow Jacket mill.

MISSOURI

GALENA. Four large mines, the Diplomat, Empire, Portia, and West Virginia are closed on account of the low price of ore. Many smaller ones have suspended since the flood 8 weeks ago.

GRANBY. Cottages for employees are to be built by the American Zinc, Lead & Smelting Company.

JOPLIN. Zinc ore had another slump last week, prices ranging from \$15 to \$65 per ton, basis 60% metal. A fair number of mines are closed. The turn-in of concentrate was the light

est for months. The yield of the district was 3217 tons of blende, 25 tons of calamine, and 622 tons of lead, averaging \$55, \$40, and \$65 per ton, respectively. The total value was \$220,617.

MONTANA

BUTTE. Its third option on 50,000 Bullwhacker shares has been exercised by the East Side syndicate, for \$25,000. Ten cars of ore sent to the East Butte smelter ranged from 4.16 to 8.92% copper.

Work has been started by the Great Butte company at the Bacon property. Boilers and pumps are arriving. A 70-ft. head-frame is to be erected. The Calumet shaft is to be deepened from 1000 to 1500 feet.

GREAT FALLS. At its Rainbow dam on the Missouri river the Montana Power Co. is to increase the capacity of the power-plant by 10,000 kw., at a cost of over \$500,000. The demand for power by Butte mines, the new zinc plant at Great Falls, and the Chicago, Milwaukee & St. Paul line renders this addition necessary. F. M. Kerr is manager, and F. Scotten superintendent. During the first half of 1916 the gross revenue was \$2,903,753, against \$1,910,297 in this period of 1915. The balance for dividends is \$1,551,604, compared with \$789,277.

HARLOWTON. It is expected that the Chicago, Milwaukee & St. Paul Railway will have its line electrified from Harlowton to Avery, Idaho, by October 1.

KENDALL. During the second quarter of 1916 the Barnes-King Development Co.'s revenue totaled \$87,773, \$83,482 of which was bullion from 13,652 tons of ore. The net loss was \$26,157, against a profit of \$26,912 in the first period. The quarter started with a balance of \$184,710, and ended with \$57,414. The Shannon mine work cost \$29,117, and the Kendall \$37,810, including \$30,181 part payment for the property. The North Moccasin mine made a profit of \$12,913, the Piegan-Gloster a loss of \$18,373. No. 2 dividend absorbed \$30,000. In July the North Moccasin yielded \$12,400 from 1622 tons of ore.

LIBBY. Nine miles from Libby the Lukens-Hazel Mining Co.'s development has been rather encouraging. The Buzz Saw claim is the centre of operations. The ore contains gold, silver, and lead.

TRON. Unusual activity prevails in this district, including work at the B. & B. mine of the Snowstorm company, and that of the new L. & U. Mining Co., 9 miles from this place. The L. & U. claims contain lead-silver veins. A 3-mile road is to be constructed to the mine. Spokane people are in control.

NEVADA

ELY. On August 1 the Consolidated Coppermines Co. suspended work, and is now doing nothing, save trying to sell bonds for overhauling the mill.

GOLDFIELD. July returns of the Jumbo Extension amounted to \$28,400 net from 1976 tons of shipping and 808 tons of dump ore. That shipped was worth \$72,500 gross. The Jumbo Extension company has passed its usual quarterly dividend. The following statement was made public: "The cash in bank and ore reserves, in the opinion of the directors, do not warrant the payment of a dividend at this time. No new workable ore has been opened in the mine for the past six months, and the production has come entirely from the ore-shoot first opened 18 months ago. The drain on reserves has been great, and the end of the productive life of the mine is not remote unless further development discloses new orebodies. J. K. Turner's plan of development will require at least \$100,000. It is also the purpose of the company, in order to perpetuate the corporation to acquire a new producing property. One year ago, having the present contingencies in view, the directors adopted a policy of keeping on hand a reserve of \$200,000, and distributing only surplus cash and ore in transit

in dividends, when the necessary amount accrued. The cash in hand and ore in transit do not permit of the distribution of a dividend for this quarter without seriously impairing the reserve and jeopardizing the future of the company."

At the Silver Pick Con. the main shaft is 880 ft. deep, and should soon enter the quartz zone which gave high assays in drill-cores. The Calyx core-drill, working on the 500-ft. level, is down 1100 ft. from the surface. Three promising veins were cut. A heavy flow of water is coming into the shaft.

A large head-frame and 45-hp. electric hoist have been installed at the Grandma shaft, which adjoins the Keweenaw on the east.

PICOCHE. One hundred miles south-west of here is the Groom district, in which Utah people are interested. The ore is in limestone and shale, containing lead and silver. It is hauled by teams and trucks to Indian on the Salt Lake Route.

SEVEN TROUGHS. It will take 30 days to overhaul the Seven Troughs Coalition mine, which was flooded a week ago by a flow of water below the 1700-ft. level. The water rose to 1500 feet.

TOSOPAH. Last week's output was 9257 tons of ore valued at \$192,706. The Extension mill treated 2200 tons. Development on the Murray vein at 1450 ft. continues excellent.

SOUTH DAKOTA

In Bulletin 627 of the U. S. Geological Survey the lignite field of the north-west of this State is discussed by four of the staff. The area covers 4900 sq. miles in Perkins and Harding counties, north of Deadwood and Lead. Lignite is present in

MAP SHOWING LIGNITE AREAS OF SOUTH DAKOTA.

nearly every part, but mostly in thin lenticular beds. Probably the greater part will never become of more than local economic importance. A few beds are sufficiently thick and persistent to warrant proper development.

TEXAS

(Special Correspondence.)—Henry Bordner and others are preparing to develop a rich cinnabar claim discovered a few months ago, 30 miles north-west of Boquillas. The outcrop is some distance from the Terlingua quicksilver district. It is stated that a 20-ton furnace and other equipment will be installed. Outcrops of cinnabar are found in many parts of the Big Bend district, but so far actual development has been confined to Terlingua and the immediate vicinity.

Boquillas, Aug. 18.

(Special Correspondence.) The Texas Graphite Co. has 75 men employed in developing a large graphite deposit near Burnet. Construction of a 200-ton mill in four units is now under way. A large quantity of graphite ore has already been mined. It contains from 8 to 12% flake graphite. Treatment will be by flotation. The company has spent a considerable sum in erecting residences for its employees and making

other preliminary improvements. The mill product will be shipped to a refining plant in New Jersey.

Burnet, August 18.

UTAH

ALTA. Rails are soon to be laid from Salt Lake City to Alta, and it is expected that the line will be operating before snow falls.

COTTONWOODS. Caterpillar-tractors are pulling 5 to 6 trailers of ore, equal to 30 tons, from Big Cottonwood. Sixty-ton loads were tried, but were too much for one tractor.

According to G. H. Watson of the South Hecla company, prospects for a largely increased tonnage being developed in the Little Cottonwood district were never brighter. There is no comparison between the work being done at present in the district with that of a few years ago. A number of projects now under way will have a vital effect on the production of the district, and it is reasonable to expect important developments in the near future. Diamond-drilling operations by the Emma Copper Co. and the Old Emma Leasing Co. are full of possibilities. Officials of those companies are searching for the continuation of the famous Old Emma orebodies that were cut off by the Montezuma fault. It is easy to understand the importance to the district of the discovery of these orebodies beyond the fault. At the mouth of the Little Cottonwood canyon the Wasatch Mines Co. has three shifts of men at work in preparation for the driving of the long drainage adit. The machinery is installed in the new power-plant, and the miners will be drilling in the near future. The recent consolidation of the Columbus Extension and the Rexall properties and the work now under way, may eventually lead to an outlet on the Little Cottonwood side for the Cardiff ore. It also offers a means for developing the Rexall property at great depth. Numerous companies are operating in the district, and there are more miners employed at present than at any time in the history of the district. Practically all of the work under way is being done along modern scientific lines. The South Hecla company is sending out all of the ore that the smelters will take at present, with good prospects for an increased tonnage later on. The Cardiff is producing ore worth \$120,000 monthly. A dividend of 25c. per share, or \$125,000, is to be paid.

ECREKA. It is understood that the Chief Consolidated is to electrify its plant. Boilers are being repaired at present.

MURRAY. The new 600-ton plant of the Utah Ore Sampling Co. commenced work last week. With the plants at Park City, Tintic, and the other at Murray the total daily sampling capacity is 2100 tons.

PARK CITY. Seven mines here last week shipped a total of 1405 tons of ore. There is increased activity throughout the district. The Keystone is to sink a shaft, working three shifts.

TINTIC. In 31 days at the Homansville mine of the Chief Consolidated the shaft was sunk 256.3 ft., a splendid record. The opening is 6 by 15 ft. in the clear, which has been timbered during sinking. For 150 ft. the shaft was in porphyry, the balance in limestone. Walter Fitch, Jr., was the contractor.

WASHINGTON

CHEWILAH. During the second quarter of 1916 the United Copper company's income was \$83,326, of which \$26,364 was profit. Ore reserves above 1000 ft. are estimated at 320,000 tons, plus 40,000 tons broken in slopes. A new contract has been made with the Consolidated company at Trail as follows: Treatment charge, \$3 per ton on crude ore and \$1 per ton on concentrates. Freight charges on a sliding scale from \$1.25 to \$3.20 per ton, according to value; settlement basis, 95% of the gold value, 90% of the silver value, and 100% of the copper value at 31¢ per pound less than the New York quotations, with 0.3% deduction for slag-loss.

CANADA

BRITISH COLUMBIA

According to R. E. Keith of Joplin, Missouri, recently interviewed at Spokane, this Province has a big future as a zinc producer. While the ores are not similar to those of Joplin, yet somewhat similar treatment should suffice. The Ainsworth and Slocan zinc deposits are very promising.

ONTARIO

COBALT. The Nipissing company has decided to increase its tailing-flotation plant to 500 tons per day.

The Mining Corporation of Canada will soon be refining all of its bullion, instead of shipping concentrate.

MEXICO

NUEVO LEON

(Special Correspondence.)—In the Concepcion del Oro, the Cerralvo, and a number of other mining districts of this part of the country foreign-owned properties are again being operated, after a shut-down of several weeks due to the acute situation that existed between Mexico and the United States. In some instances these mines are still in charge of trustworthy Mexican employees. The Minerals and Metales company, which owns extensive mines at Guadalupe, 50 miles north of Monterrey, recently resumed operations on a larger scale than at any time since the revolutionary troubles began. It is owned by Germans, and this is said to assure the property protection by the de facto Government. Recently large shipments of machinery for the mines and smelter of the company were brought in, and development is to be extended. The company has also imported steel rails and other material for building a spur-track from its mines to a connection with the Monterrey-Laredo division of the National Railways of Mexico.

It is reported here that the American Smelting & Refining Co. will make another effort to operate its plants at Chihuahua, Monterrey, and Aguascalientes as soon as the necessary supplies of coke can be obtained.

Comparatively few Americans have returned to the rich Guanajuato mining district since the general exodus occurred when war between the two countries seemed to be imminent. Conditions in that district are about as bad as could be pictured. Thousands of Mexicans who were thrown out of employment by the closing down of the mines are on the verge of starvation. In the mining districts and cities of the States of San Luis Potosi and Zacatecas this distressing condition exists even to a worse degree than in Guanajuato.

Monterrey, August 17.

KOREA

July results on the Suan Concession of the Scout Mining Co. are given below, and show a good improvement over recent months, particularly when it is considered that half of the Hukol mill—20 stamps, etc.—is still being used for testing purposes on the ore of the huge Sotcharie low-grade deposit of gold, copper, and tungsten. This naturally cuts down the returns from that mill. On the other hand the Tul Mi Chung mill shows a large gain in returns this month and improved extraction. The tungsten ore is proving better than expectations for this experimental work.

Mills worked, average days.....	29
Ore treated, tons.....	17,510
Bullion recovered.....	\$ 29,970
Concentrates.....	119,930
Total recovery.....	149,000
Expense.....	57,500
Operating profit.....	91,500

The complex ore occurs as a mineralized band—8 to 10 ft. wide—of quartzite inter-bedded in limestone.

Personal

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

M. L. REQUA is examining properties in Alaska.
H. F. ARMSTRONG is with the Weringer Mines Co. at Woody, California.

EDWARD B. DURHAM is now with the Mammoth Copper Co. at Kennett, California.

P. H. CRAWFORD of Divisadero, Salvador, is returning to Palo Alto, California, for a holiday.

S. YASUKAWA, of the Sado mine, Mitsubishi & Co., Japan, is visiting mines in the United States.

H. W. ROSS has been appointed assistant manager for the Backus & Johnston Co. at Casapulca, Peru.

POPE YEATMAN, for several years with the Guggenheim companies, resumes private practice on September 1.

EDWIN S. BERRY will engage in consulting mining engineering after September 15 with offices in New York.

CURTIS F. BURR of Yerington, Nevada, was married on August 5 to Miss Bessie Shields of Hancock, Michigan.

FREDERICK BRADSHAW of the Tonopah Belmont is at its Surf Inlet mine on Princess Royal island, British Columbia.

W. J. ELMENDORF has returned to Seattle from Nevada, and will proceed shortly to the Copper River district, Alaska.

I. KAMIMURA, chief engineer for the Osaruzawa mine, Mitsubishi & Co., Japan, is visiting at Kennett and the oilfields.

ROBERT LIVERMORE, manager of the Kerr Lake mine at Cobalt, has resigned; H. A. KEE of the Nipissing succeeds him.

C. A. RANDALL, mill superintendent for the Tough Oakes company, Ontario, has gone to Cuba to supervise erection of two mills.

WILLIAM B. PHILLIPS has resigned as President of the Colorado School of Mines and returned to professional practice at Austin, Texas.

HOWARD C. PARMELEE, western editor for *Metallurgical and Chemical Engineering* of New York, has been elected president of the Colorado School of Mines.

F. W. TRAPIGEN has resigned as professor of metallurgy in the Colorado School of Mines to accept the presidency of the Colorado Metal Mining & Reduction Company.

T. R. HUNT left London about August 1 for the San Juan Mines property, Rodeo, Argentina, where he is to take charge.

EDWARD THORNTON, superintendent of the Bush-Baxter mine, Twin Buttes, Arizona, has been transferred to Silverbell, as superintendent of the Imperial mine of the American Smelting & Refining Company.

MORTON WEBBER has returned to the practice of his profession after being invalidated for wounds received while fighting with the British forces, and resumes his association with ELLIS P. EABLE of New York City.

W. R. HAMILTON announces that he has withdrawn from the management of Montebello Oil Co. and affiliated companies, to engage in general engineering work in petroleum and metal mining with offices in the Hobart building, San Francisco.

Obituary

C. W. H. KIRCHOFF, of New York, died on July 23 at the age of 63. He was born in San Francisco, and graduated from the School of Mines at Clausthal, Germany. From 1883 to 1906 he was with the U. S. Geological Survey, collecting statistics on copper, lead, and zinc. From 1889 to 1910 he was editor of *The Iron Age*. In the early '80s he was with the *Engineering and Mining Journal*. During his membership of many technical societies, Mr. Kirchhoff was president of the A. I. M. E. He is survived by a wife, brother, and two sisters.

THE METAL MARKET

METAL PRICES

San Francisco, August 22.

Antimony, cents per pound.....	14
Electrolytic copper, cents per pound.....	28.75
Pig lead, cents per pound.....	6.75-8.00
Platinum: soft and hard metal, per ounce.....	\$65-69
Quicksilver: per flask of 75 lb.....	\$72
Spelter, cents per pound.....	11
Tin, cents per pound.....	41
Zinc-dust, cents per pound.....	20

ORE PRICES

San Francisco, August 22.

Antimony: 50% product, per unit (1% or 20 lb.)....	\$1.00
Chrome: 40% and over, f.o.b. cars California, per ton.....	13.00-16.00
Manganese: 50% product, f.o.b. cars California, ton.....	12.00-16.00
Magnesite: crude, per ton.....	7.00-9.00
Molybdenum: 50% and over, per pound.....	0.60-1.15
Tungsten: 60% WO ₃ , per unit.....	20.00

The tungsten market in Colorado is somewhat better, fair sales of concentrate being reported.

EASTERN METAL MARKET

(By wire from New York.)

August 22.—Copper is higher on account of heavy buying; lead is advancing on better demand; spelter is firm but quiet.

The tendency of prices has been somewhat erratic during the current week. The latest London advice states that on several occasions rather heavy sales have been made attributed to state banks and other exceptional sources. When Eastern rates are discounting buyers hang back, knowing that the market lies in their hands, but when rates are added steady they are only too glad to take whatever offer. America has been selling less freely. The silver reserve in the Indian treasuries continue to increase, but as in preceding weeks the total of the note issues is enlarged to about the same extent. Exports

of silver from London to India to August 2 amount to 11,427,500, compared with \$2,955,000 in this period of 1915. The good demand for coinage still continues, while there has also been some inquiry on speculative account, the moderate supplies being easily absorbed. The Indian Bazaars still seem to consider that the present level of prices is high enough, for, although purchases have been made for that quarter, sales on that account have predominated. This increase of the Indian bear account should prove a factor for strength later on, as the amount now open is by no means a negligible quantity, while the demand for coinage should prevent any weakness in the near future, although China exchanges are still lagging behind.

Tin is steady at 35.25 to 35.35 cents.

Eastern Metal Market

New York, August 16.

Practically all the metals show an improvement in prices and tone.

Copper is stronger and more active and second-hand metal has practically disappeared. The probable foreign purchases dominate the situation.

Zinc is higher, with demand from foreign and domestic consumers increasing rapidly.

Tin is advancing on fair sales with inquiry considerably better.

Lead is stronger and the price slightly higher.

Antimony is again rising after a decline to a point regarded as the bottom.

Aluminum continues firm.

Domestic buying of steel has developed to an extent not seen in weeks. This comes as a result of large War and other export orders recently placed. Estimates put the total number of large shells ordered in the last two weeks at 3,000,000, besides 500,000 tons of shell-steel has now been ordered by the Allies. Pig-iron is brighter, with signs that a buying movement, expected in September, has already started.

COPPER

Some brokers are of the decided opinion that the copper market is stronger than at any previous time. It is true that inquiry for both foreign and domestic account has broadened extensively. The market has been full of rumors of the probable purchase by various foreign governments of large quantities of copper, estimates of their needs running from 250,000,000 to 350,000,000 lb. Some regard this as largely talk, as so far prices have failed to advance to any extent. Others report a good business having been done in both foreign and domestic. Inquiries from domestic consumers have been stimulated by the prospective foreign purchases, because of the desire to anticipate this buying. In some quarters it is the opinion that force has been attempted by these rumors to bolster-up prices. At any rate the whole tone is stronger and better, and there is no evidence of weakness anywhere. The quotation for spot at this writing is 27c. cash, New York, with last-quarter metal obtainable at 26 to 26½c. It is reported there is little near-by copper available. The London quotation yesterday was £126, compared with £124 a week ago. Exports in 16 days were 13,456 tons. Lake copper is nominal at 26.75c. cash. One broker considers that already at least 125,000,000 lb. of the prospective foreign needs has been negotiated for 1917 delivery, the sales being apportioned among large producers by the American Smelting & Refining Co. as the chief distributor. A rumor that the Central Powers were also purchasers or inquirers cannot be substantiated. Any purchases they might make would be for delivery after the War.

ZINC

A decided change has come over the market and demand yesterday was reported, at least by one broker, as more active than at any time in several months. He characterized the tone as unusually strong. Inquiries were numerous in lots of 250 to 1000 tons, and some good business was done. The demand comes not only from foreign sources, but also from domestic consumers, among whom are the brass mills and especially the galvanizers, who are regarded as about to cover for fourth-quarter needs. Prices have been advancing during the past week until yesterday spot metal at New York was quoted at 9c., and 8.75c. at St. Louis. One broker said he turned-down an inquiry for 1000 tons at 9c. yesterday. For last quarter 8.25 to 8.50c., New York, is asked. The demand has been for

both near-by and fourth-quarter delivery. Exports so far this month, including yesterday, were 2649 tons. Sheet zinc is still 15c. for carload lots f.o.b. smelter, 8½ off for cash.

LEAD

The market is stronger and demand is better, a spurt having manifested itself early this week. The entire tone is strong and prices are a little higher. The quotation today is 6c., New York, and 5.90c., St. Louis. Inquiry is increasing from both foreign and domestic sources, and some good sales are reported. The independents have been recently under-selling the leading interest, but yesterday their price had nearly reached the latter's. Exports this month, up to and including yesterday, were 75½ tons compared with 429 tons a week ago. The London market yesterday was £30 for spot and £29 15s. for futures. The tone of the market is much less pessimistic.

TIN

There has been more interest in the market in the past week and the feeling is better. Some sellers reported a good demand at one time, while others at the same period took a contrary view. This attitude was later reversed by both parties so that the market has presented a queer aspect. But a decided improvement is certain and there have been substantial inquiries and some fair sales. On the 9th there was a good demand for Banca tin with a fair quantity sold, as well as some Straits tin for Eastern shipment—probably 200 to 250 tons in all. The market was quieter on the 10th with inquiry fair but apparently no sales. The next day, however, it developed that at least 225 tons had been sold on the 10th. On the 11th dullness appeared but late that day a boom started resulting in sales of over 200 tons. Saturday inquiry was good and more tin could have been sold had there been more sellers, but at least 100 to 150 tons changed hands. This week there have been moderate sales, mostly for spot, August and September delivery. Yesterday the market was again dull with spot Straits quoted at 39c., New York, against 39½c. the day previous. Arrivals up to August 16 total 2497 tons, with 3135 tons afloat.

ANTIMONY

It is believed that the bottom of the decline was reached when Asiatic grades sold as low as 9½c. last week, duty paid. A turn has recently been evident with a much better demand and some business done with Canada. Yesterday the metal had advanced to 10 to 10½c. duty paid. In all, several hundred tons are said to have changed hands. There is little business in needle antimony at 8 to 8½c. per pound.

ALUMINUM

The market is firm at 59 to 60½c. per lb., for No. 1 virgin metal, 98 to 99½ pure. A month ago 60c. was asked, and one year ago it sold as low as 31c. The high price for 1916 thus far has been 65c., with 41c. as the low.

ORES

Antimony: There has been practically no business during the past week, the last sale of small lots having brought \$1.10 to \$1.20 per unit.

Tungsten: This ore is nominally \$20 to \$25 per unit, but the prospect for a higher market is brighter. The foreign demand is a dominating factor, and considerable quantities have been sold recently to foreign countries thus diverting shipments from the United States and absorbing some of our stocks. In addition, on July 19 Japan prohibited the exports of tungsten and molybdenum except under license. These facts tend to a more steady market.

Company Reports

CHINO COPPER CO.

Reports covering the second quarter of 1916 are as under:

Overburden removed, cubic yards	871,138
Ore treated, tons	788,500
Average metal-content, per cent	1.79
Copper production, pounds (including precipitate).....	18,157,923
Average price received, cents per pound	27.49
Cost, cents per pound	8.89
Profit	\$3,221,969
Dividends paid	1,957,455
Surplus	1,264,514

The monthly yield was 610,000 lb. more than in the previous period, when the price was 26.57c. per pound. While the profit was \$470,000 more, the surplus is \$400,000 less, after paying an increased amount of dividend, \$770,000. The mill is to be improved to treat oxidized ore and tailing.

UTAH COPPER CO.

During the period construction started on additions to the mills and for the new leaching plant. The former work will increase their capacities and recoveries.

Overburden removed, cubic yards	1,659,594
Ore treated, tons (a record).....	2,758,500
Average grade, per cent.....	1.381
Recovery, per cent	63.51
Copper production, pounds (a record).....	48,384,929
Cost, cents per pound	6.726
Profit, including dividends received, etc.....	\$9,958,317
Price received, cents per pound.....	26.758
Dividends paid	4,873,470
Surplus	5,084,847

RAY CONSOLIDATED COPPER CO.

Development, feet	16,217
Cost of mining and coarse crushing, cents per ton....	80.85
Ore treated, tons	865,300
Average content, per cent	1.631
Cost of treatment, cents per ton.....	51.41
Copper production, pounds (with crude ore smelted).....	19,171,238
Cost, cents per pound	10.507
Profit	\$3,242,542
Dividends	788,590
Surplus	2,453,952

Over 110,000 tons more was treated, the yield was 3,300,000 lb. greater, the profit was an increase of \$1,000,000 and the surplus \$1,000,000 more than in the first quarter. Dividends were practically the same.

The profit was almost \$3,000,000 larger than in the March quarter. There was no unsold copper on hand at the end of the term. Costs were lowered 0.251c. per pound. The surplus shows a gain of over \$2,000,000.

BUTTE & SUPERIOR MINING CO.

In the second quarter spelter averaged 11.11c. per pound, in the first 16.1052c.; the total net profit was \$292,029, against \$555,510, a large decrease due to low metal prices. Dividends absorbed \$10.75 per share. Net quick assets are \$3,300,000, an increase of over \$300,000. Sales of spelter for future delivery have been made, covering a good proportion of production in the remainder of 1916.

At the mine a great deal of shaft work was done. Development commenced at 1700 and 1800 ft., where as far as opened, the character of the orebodies is as favorable as in the levels

above. Reserves increased 30% above the quantity extracted. Work beyond the Black Rock claim was especially gratifying. The cost of mining was \$4.971, an increase of 46.3 cents.

Mill results were as follows:

Ore treated, tons	161,270
Zinc-content, per cent	15.9709
Silver-content, ounces	6.7041
Zinc-content of concentrate, per cent.....	52.9956
Silver-content of concentrate, ounces.....	21.8757
Zinc in concentrate, pounds.....	47,901,445
Recovery, per cent	92.989
Cost of treatment, per ton	\$1.761

Milling results generally were almost the same as in the previous term, although costs were 18.47c. higher. All costs were \$6.2581, against \$5.6104 per ton.

NEVADA CONSOLIDATED COPPER CO.

Ore treated, tons (12% from underground).....	1,094,879
Metal-content, per cent	1.57
Copper production, pounds	24,091,021
Price received, cents per pound.....	27.23
Cost, cents per pound	8.51
Earnings	\$4,853,945
Dividends	1,499,593
Surplus after depreciation and ore extinguishment.....	3,059,917

Comparing with the previous quarter there was 167,999 tons more treated, the output was a gain of 4,930,747 lb.; and the price was 1.66c. per pound higher.

ARGENTINE RAILWAYS. A review of their position, conditions, and prospects. By Leopold Grahame. P. 36. Illustrated. Rensselaer, Lyon & Co., New York, 1916. A map would have improved this interesting booklet.

STRENGTH AND OTHER PROPERTIES OF CONCRETES AS AFFECTED BY MATERIALS AND METHODS OF PREPARATION. By R. J. Wig, G. M. Williams, and E. R. Gates. Technological paper 58. P. 172. Illustrated. Bureau of Standards, Washington, D. C., 1916. It includes the results of about 20,000 tests on 300 aggregates consisting of limestone, granite, gravel, and trap-rock which are used for concrete materials in various parts of the United States. The conclusions are of especial interest to contractors, engineers, architects, and others who use concrete, since it points out that with the same aggregates a variation in strength of as much as 100% may result owing to the lack of proper precautions in mixing and placing the material.

EDITORIAL

T. A. RICKARD, Editor

THE metal market is better than for some time past, and readers will find our New York letter this week worthy of attention. The lead situation is interesting.

ANTIMONY miners and smelters have experienced a dull time lately, the price of their product dropping from 45 cents to 9 cents, and at the latter figure the metal was almost unsaleable. The market is now much stronger in tone, with an advance to 14 cents, as a consequence of under-estimation of stocks by the trade, renewed buying, and considerable sales for munitions' purposes.

INCREASED wages are asked by miners of Amador county, California, on account of the high cost of living. The men receive from \$2.75 to \$3.25 per shift, which includes a 25-cent raise granted some time ago. Now they speak of an additional 50 cents per day. The mine-owners say that this cannot be given, as the cost of supplies has increased so much. There is quite enough labor unrest in the country at present, and it is to be hoped that this latest dispute will be settled amicably.

RECENTLY we commented on the Calumet & Hecla semi-centenary. The president, Rodolphe L. Agassiz, has given some interesting figures to the *Boston News Bureau* regarding 50 years of operation. The copper output was 2,686,896,000 pounds, equal to 1,343,448 tons. Dividends amounted to \$132,250,000. The most significant feature—and one that might be profitably noted by the Western Federation of Miners, now the International Union of Miners, Mill, and Smelter Men, is the amount paid in wages, namely, \$129,230,938, nearly equal to the dividends.

FLOTATION is elucidated in this issue by Mr. Will H. Coghill. He offers an analysis of the molecular forces that are at the back of the curious phenomena of frothing. While some of our readers may prefer a description of the application of the process in a mill, it is certain that our methods of concentration by flotation will not improve until we get a firm grip on the essential principles of the physics involved. This is being recognized by the mining companies. Even if they have not sent members of their staff to engage in research work in university laboratories, they have, we believe, in several instances commissioned metallurgists to make special investigations. The better-equipped mines have laboratories in which a great deal of research work is being done and we would only venture to suggest that

those doing such work should be given a chance to collaborate with physicists. The metallurgist must approach the fundamentals of flotation from the physical, not the chemical, side. There he is weak admittedly. In the same way the study of flotation in mining-schools is left too much to the metallurgical department, aided by the chemical, ignoring the fact that the strange features of the process can be explained only in terms of physics. His writing on the subject, in this issue, will well repay careful study, for he has the scientific spirit, which never rests until it gets at the truth. Comments or criticisms on his article will be deemed a compliment by him and by us.

IN our issue of April 8, 1916, we gave some particulars of the smelter to be erected at Kellogg, Idaho, by the Bunker Hill & Sullivan company. We note with pleasure that on August 19 the beginning of actual construction was duly celebrated by the company, its employees, and citizens of Kellogg. A feature of the proceedings was the presentation of several bars of lead by the general manager, Mr. Stanley A. Easton, to public institutions, these bars being the first made in the Coeur d'Alene. We hope that our next announcement concerning this smelter will chronicle the blowing-in of the furnaces.

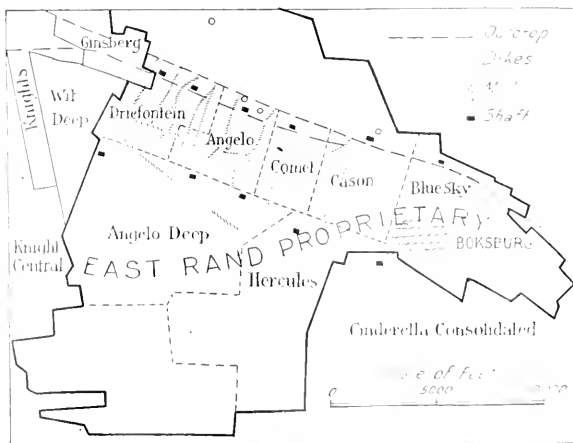

BOLIVIA has come to the front in tungsten production during the past two years. In the first three months of 1916 there was exported—75% to the United States and 25% to Europe—608 tons of wolfram, containing 65% tungstic acid. This does not indicate the production, as it is said that considerable quantities of ore are being stored until the end of the War. Of the output, 69% comes from Oruro, 19% from La Paz, the remainder from Potosi, all well-known centres in connection with the tin industry. During the whole of 1915 wolfram exports were only 625 tons. The antimony yield is also gaining in importance. In the first quarter exports amounted to 7191 tons of high-grade ore valued at \$1,500,000, as against 509 tons in the same period of 1915. Regarding wolfram it may be added that two years ago only two companies were extracting this mineral; now there are over two hundred.

TUNGSTEN producers, especially those in Colorado, are optimistic regarding an early rise in price, now \$10 to \$20 per unit for 60% concentrate. New war contracts necessitate more high-speed tool-steel. The foreign demand is increasing, and shipments from South

actual performance during the ensuing decade, we should have a body of evidence of the greatest value to the engineers engaged today in making similar appraisements. But reports on mines constitute a kind of literature that few people take the trouble to preserve. Therefore we lose the benefit of much useful information. However, here we have some examples. Nine years ago a detached onlooker of some experience in these matters undertook to prepare a list of the principal gold mines. Let us see what happened. In that list there were five South African mines. Of these, the Cason is now a part of the East Rand Proprietary, a consolidation that became the victim of a fiasco in 1911, when a depreciation of \$30,000,000 in the market-value of the property took place within a few months, followed by a further depreciation of \$17,750,000 in the three ensuing years, so that shares quoted as £5½ sank to £1½ on a capital of 2,445,897 shares, indicating a loss of over \$50,000,000. It was proved that the capacity of the mine had been hugely over-rated, the mill-returns had been juggled, and a number of relatively worthless properties had been included within the consolidation in order to enable their owners to realize upon them at the expense of the public. From that shock the South African market has scarcely recovered yet. The Cason, which in 1907 was earning a profit of \$174,000 (£1 being taken at \$4.85) monthly from an output of 36,500 tons, in 1915 averaged a profit of \$265,115 from 165,300 tons monthly. Thus the tonnage was more than quadrupled, while the profit increased to about one-third more than it was nine years earlier. The grade of ore declined from \$10.31 to \$6.25 per ton, while the cost decreased only from \$5.51 to \$4.75, despite the enormous growth of tonnage. It is evident that the Cason has proved a disappointment, although on the whole it has done better than some of the other mines included in the East Rand Proprietary. The next mine on the select list was the Simmer & Jack, which, in 1907, was treating much the largest tonnage of any mine on the Rand. In that year its monthly average was 62,200 tons, yielding \$505,500 gross, and \$226,000 in profit on \$8.12 ore. During the year ended June 30, 1915, the mill treated 68,122 tons monthly for a gross yield of \$350,250 and a profit of \$133,600 on ore averaging \$5.34 per ton. Here again the tonnage has been increased, but not much, while the yield and the profit have fallen considerably. The mine is nearing its end, having only 2,428,000 tons remaining, or enough ore to last three years. It has fulfilled expectations fairly well. These mines on the Rand have no extra-lateral right, so that their future prospects are delimited by the side-line. When an 'outcrop' mine, that is, one located so as to cover the outcrop of the gold-bearing beds of conglomerate, or 'banket,' is worked out on the dip up to a line vertically under its surface boundary on that side, it has to stop: the property owning the ground covering the continuation of the lode on its dip is called the 'deep level.' This is the relation of the Simmer & Jack to

the Simmer Deep, of the Robinson to the Robinson Deep, of the Village Main Reef to the Village Deep, for example. The lack of apex-rights limits the future prospects of an 'outcrop' mine, but the existence, below its ultimate bottom, of workings due to the operation of the corresponding 'deep level' mine serves to sample the ground, so that the resources of the property are ascertainable with a completeness comparable to the appraisal of an alluvial area that has been carefully drilled.

Next we come to the Robinson, which is among the great mines that have made good. At the beginning of 1907 the output was 31,100 tons monthly, yielding \$438,500 gross, and a profit of \$286,000, on an ore averaging \$14.10 per ton. In 1915 the average output was 57,400 tons, yielding \$387,690 gross, and a profit of \$198,225 monthly, on ore averaging \$7 per ton. The grade has been lowered to one-half what it was and the cost has been reduced from \$4.90 to \$3.40 per ton, so that with a tonnage nearly doubled, the profit is 30% less. This decline in profit has been marked only in the last two or three years. The Robinson is now nearly exhausted, but it has fulfilled its promise handsomely, as we shall see on further analysis later. The Robinson Deep, which follows the Robinson on the dip of the banket, was producing 38,800 tons monthly in 1907, yielding gold worth \$414,000, and a profit of \$209,000 on ore averaging \$10.68 per ton. During the year ended July 31, 1915, the average monthly output was 50,583 tons, yielding \$348,784, of which \$125,388 was profit, on ore averaging \$6.80 per ton. In this case also the resources of the mine are near an end,

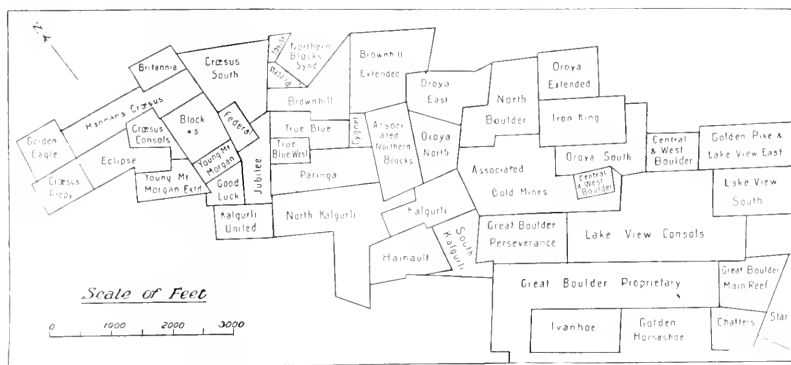

THE EAST RAND PROPRIETARY.

the ore assured amounting to 1,787,000 tons averaging \$6 per ton, or enough for three years only, with no chance of further discovery. The fifth South African mine cited by us in 1907 was the Village Main Reef, which at that time was producing 37,100 tons monthly for a gross yield of \$315,000 and a profit of \$119,000 on ore averaging \$8.50 per ton. During 1914 and 1915 the mine suffered from 'air-blasts' or settlements of rock, caus-

companies, the 'profit' is a mere bit of book-keeping, the real gain, as measured in dividends, being considerably less. In 1915 the 'profit' was £473,443, while the dividends amounted to £335,500. From September 1884 to the end of 1915 the Mysore mine produced 4,525,871 tons of ore, yielding \$82,743,891 in gold, and paid dividends aggregating \$39,287,961. The Champion Reef, which adjoins the Mysore and exploits the same lode on the downward pitch of the ore-shoots, was producing 16,730 tons of \$12 ore in 1907, winning \$202,000 gross and \$65,000 profit monthly. In 1915 the average output was 17,614 tons of \$11.45 ore, including yield from tailing, making \$220,040 gross and \$84,875 profit monthly. Evidently the ore has maintained its grade, while the cost has been reduced from \$7.66 to \$7.04 per ton. The increase of tonnage and decrease of cost have enabled the company to increase its dividends. In 1907 the total yield

has come an inglorious smash. In the summer of 1910 the shares, which had stood at £10½, began to fall on rumors from New Zealand. As a matter of fact, the contraction of the orebodies below the zone of oxidation became apparent in 1909. In August 1910 the Geological Survey of New Zealand began a study of the district, eliciting information unfavorable to the future of the mine. But the information was not given to the shareholders, so that the news came suddenly and disastrously in 1911. The ore in reserve at the end of 1915 was stated as 806,000 tons, besides 673,900 tons in pillars and remnants, so that the mine has a life of seven or eight years, at least, and some chances, slender, it is true, of rehabilitation. The output of gold and silver to the end of 1915 is \$53,904,937 from 4,790,403 tons, of which \$24,755,525 was distributed in dividends.

The great bonanza in the Esperanza did not last long.

MAP OF GOLD-MINING PROPERTIES AT KALGOOLIE.

was £500,189 and the dividends £104,000; in 1915 the yield was £545,338 and the dividends £147,333. From 1892 to the end of 1915 this mine has produced 3,607,487 tons, yielding \$58,464,375 in gold and \$20,879,085 in dividends. The ore-shoots have a pitch of about 45° southward, so that the question of downward persistence is determined for the Mysore by the evidence obtainable in the Champion Reef ground. The latter did handsomely until about 11 years ago, when it had attained a depth of 3700 feet. In 1905 the dividends were £416,000. Since then the length of stoping ground has contracted. The greatest vertical depth attained on this lode is 4670 feet, in the Oregon mine, south of the Champion Reef, which itself has a shaft 4340 feet deep. The Mysore is down to 3465 feet vertically, or 5000 feet on the dip of the lode. These mines are still to be ranked among the big fellows, but they exhibit signs of impoverishment, and the value of their reserves is not known owing to the fact that the managers state the tonnage of ore assured but they do not state the average gold contents of it. However, they have made a splendid record, they have been wisely administered, and the statistical evidence proves that they were properly classed among the great producers of gold.

The Waihi, which ranked among the very best in 1907,

although the mine has continued to be productive. This property, at El Oro, Mexico, came into sudden prominence in 1904, the shares jumping early in 1905 from \$5 to \$30. Three years later the rich ore had been worked out, but since then more ore of medium grade has been found by intelligent exploration. It is doubtful whether the Esperanza should have been included in the list of the great gold mines; it yielded one of the most remarkable orebodies and made a spectacular production for a short time, but it never had the assurance of continued richly productive life such as characterizes the mines of the very first rank. In 1906 this mine produced 150,047 tons, yielding \$4,548,975, out of which \$3,420,162 was paid in dividends. The ratio of gold to silver, in value, in the ore is as 4:1. The total production from October 1903 to the end of 1915 has been 2,085,936 metric tons, yielding \$36,172,019, from which dividends of \$11,971,620 have been paid. In 1914 the output was 120,975 tons, which, with the re-treatment of 45,237 tons of tailing, yielded \$1,039,698, of which \$402,426 was profit. So it is evident that the mine is still a notable producer. In 1915 operations were crippled by the Mexican revolution. Ore reserves are estimated at 156,000 tons, containing a profit of \$532,000, or enough for over a year.

Two American mines were included in the list; of these the Camp Bird is practically exhausted, unless the unexpected happens and new orebodies are found by the deep adit now being driven far below the existing workings. Even in 1907 it was known that the showing in depth was poor and that future production depended chiefly on lateral development. But the Camp Bird has done well. From April 30, 1903, to June 30, 1915, it produced 795,129 tons yielding \$22,152,297, or \$27.86 per ton. The profit distributed had been \$14,427,090, to which must be added the \$1,500,000 used in the purchase of the Santa Gertrudis, which is controlled by the Camp

THE INDIAN MINES.

Bird company. The mine was discovered in 1896 and yielded \$4,035,500 gross and \$2,100,000 profit to Thomas F. Walsh before it was sold to the English company, so that altogether it has yielded \$26,187,797 gross and \$18,327,000 in actual profit. The Camp Bird has done all that was expected of it and a good deal more. The shares were never kited, so that the public had a good run for the money put into this mine. The Homestake is doing just as well as nine years ago. It has proved a wonderful mine. In 1907 the monthly output was 120,250 tons of \$3.85 ore, yielding \$154,000 gross and \$135,000 net, at a cost of \$2.73 per ton. Now the average output is 131,000 tons of \$4.08 ore, yielding \$535,750 gross and \$184,181 net, at a cost of \$2.65 per ton. By supplying 10,000 tons more monthly to the mill, the cost has been reduced

while the yield has been more than maintained. In 1914 the yield was \$3.88 and the cost \$2.89. The dividends paid during the calendar year 1915 amounted to \$2,210,208 as compared with \$1,201,200 in the year ended May 30, 1907. The company's fiscal year has been changed. This mine therefore is doing almost twice as well, in terms of dividends, as it was nine years ago. What ore is in reserve is not stated.

Next we come to the Mount Morgan, in Queensland. This mine has become increasingly important as a source of copper, the ore averaging 2.6% copper, worth (at 17 cents) \$8.84, and 7.7 dwt. gold, worth \$7.70. In the half-year ended May 28, 1916, the Mount Morgan produced 208,676 tons of ore yielding 3997 tons of copper and 57,352 ounces of gold, together worth \$2,930,000, equivalent to 34,780 tons and \$488,300 monthly. The surplus was \$858,450, or \$143,075 per month. This compares with 26,275 tons, \$404,000 gross, and \$147,500 profit per month at the beginning of 1907. In the latter half of 1906 the output of copper was only 1751 tons of blister and 172 tons of precipitate, and the total revenue in that period was \$2,173,482. The yield in copper and gold is \$13.65 now as compared with \$15.36 then. Evidently this mine is still going strong. The control passed into new and capable hands in 1913, when a purchase of 350,000 shares (out of 1,000,000) for \$6,250,000 marked the withdrawal of the Hall family out of this enterprise. The profit had been disproportionate to the gross output and the management had lacked initiative. Since then the plant has been re-modeled. From 1882 to November 30, 1915, this great ore deposit had yielded 4,147,000 ounces of gold, worth \$85,335,750 and 65,600 tons of copper, worth \$18,973,200, or a total of \$104,309,950, from which \$40,396,455 has been paid in dividends. Production of copper began in 1906. In 1911 the Many Peaks mine was purchased as a source of low-grade pyrite suitable for mixing with the silicious ore of the Mount Morgan deposit. Chlorination was abandoned shortly thereafter in favor of matte-smelting. At the end of 1915 the ore reserve was estimated at 1,000,000 tons, averaging 3½% copper and 9.81 dwt. gold, 2,930,000 tons averaging 2.42% copper and 5 dwt. gold, also 496,000 tons of 1.19 to 2.46% copper and 6.9 to 1.02 dwt. gold per ton.

Summarizing the performances of these 16 mines during the 9 years, it is apparent that four proved sad and expensive fiascos, owing to human frailty rather than geologic perversity; twelve justified the estimates formed of them by competent engineers, and of these twelve, five still hold their rank among the great producers of gold. Four, possibly five, out of the sixteen were given so inflated a value on the share-market that they were the cause of large loss to the public. Allowing for these examples of over-valuation, aided by chicanery on the part of market-operators posing as trustees for the shareholders, it is evident nevertheless that these rich mines have been the basis for a wonderfully profitable business.

In a later article we shall discuss the question: Which is the greatest gold mine in the world?

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor reserves expressions of views contrary to his own, believing that careful criticism is more valuable than casual complacency.

Gyratory Crushers

The Editor:

Sir—Owing to the fact that repairs cause a large reduction in the profits of every rock-crushing plant, I believe the following will be of interest to some of your readers. I have had a great deal of trouble with gyratory rock-crushers due to breaking. A crusher which has the bowl and bottom spider cast in one piece, often breaks in the spider from contraction and expansion. I hit upon the plan of having the spider cut out and a new one cast of steel, with the legs larger than the old one and made with a shoulder that projects below the rim of the bowl. After having both bowl and legs milled smooth, the spider is pressed into place and fastened with four 1½-inch stud-bolts in each leg.

I now have in use three crushers that have been repaired in this manner and they seem better than new ones. The bowls of this size cost about \$600 at the factory while the repairs cost about \$150.

Postage to South America

The Editor:

Sir—Your editorial of June 17, discussing deficient postage to foreign countries, should have been printed in 'box-car letters,' and I would like to stamp it at the bottom of every letter that I write to the United States.

Since my arrival in Chile five months ago, about one-half of the first-class mail that has come to me from the United States has been held up at the local post-office and fined for lack of sufficient stamps. This apparent ignorance of postal regulations affecting foreign countries is inexcusable. I am reliably informed that the 'frank' privileges of the U. S. government does not extend to South America.

If the people in the United States expect to permanently increase their business with South America, they should give serious heed to your advice, and do all possible to avoid these little but intensely irritable faults. If it makes a loyal American citizen hot to have a large proportion of his mail materially delayed, and to have to pay a money fine for such carelessness, it is not to be expected that our South American friends will be more tolerant. As a matter of fact, I believe that such little things cut a good deal more figure in our daily business dealings than we realize, and that persistent failure in

attention to small details has a decided bearing on our estimates of the people with whom we deal.

LOUIS A. WRIGHT.

Santiago, Chile, July 13.

Surficial Indications of Copper

The Editor:

Sir—One or two points occur to me in connection with Mr. Probert's interesting articles that may be worth mentioning. His opinion on the possibility of guessing at the probable copper-content of primary ore from the color and consistence of the surface iron stain and of the gossan would be valuable. Has Mr. Probert found that a dark, rich, golden-oak or mahogany-colored surface stain usually indicates that the primary ore was fairly rich in copper, while a lighter yellow or bright-red stain indicates that the primary ore was lean in copper, requiring great enrichment to form commercial ore? Also I should like to know whether, unlike most of us, Mr. Probert has any explanation for this coincidence.

In his third article, Mr. Probert speaks of a sandy, granular pyrite in the Briggs mine here, associated with enriched chalcocite ore. While there is a lot of this sandy pyrite with limonite seams and stains, it is by no means a certain indication of ore. Apparently when well-formed pyrite crystals are cemented by finer grained, less crystallized pyrite, part oxidation will cause an iron-stained pyrite sand similar to that which is formed when the cementing material between the pyrite grains consists largely of copper sulphides.

Warren, Arizona, August 15.

Prospecting

The Editor:

Sir—In the issue of July 22, Harold French outlined a scheme for co-operative prospecting, which requires the combined capital of 20 investors and the efforts of several skilled prospectors under the direction of a mining engineer. In the issue of August 12, John B. Platts throws cold water on the plan and says that it would not succeed in practice. The objections given are that skilled prospectors would not work for less than a half interest in a discovery, and that it is "extremely unlikely that there are any undiscovered visible outcrops of profitable ore on the public domain." Permit me to suggest that

no business scheme will succeed unless it is backed by confidence. It is likely that Mr. French, who believes in the idea, could organize a party of prospectors and stand a chance of unearthing something valuable. Mr. Platts probably would not 'make a go' of the plan, because he does not believe in it. It is so of any venture where the human element is important. Some men are always doing things that others said cannot be done. As to the statement that no "undiscovered outcrops of profitable ore" remain on the public domain, this may be true if the "outcrops" are such as any novice could spot as being valuable without effort. Mr. Platts can scarcely mean that no new mines will be discovered by prospectors. A chance blast here, a test-pit there, the extension of an old tunnel, the recognition of a commercially-new mineral, the skilled examination of an abandoned prospect-hole, all contain possibilities, especially in these progressive times. In the oldest of settled countries new mineral finds are constantly being made. Outcrops that men have looked at unseeingly for years are sometimes found to contain valuable mineral just under a surface stain or beneath a cover of moss. The rewards may not be so apparent as a generation ago, but prospecting isn't quite dead yet.

Berkeley, August 21.

P. B. McDONALD.

Another Apex Decision

The Editor:

Sir—Referring to your editorial on this subject in your issue of July 22, I note another of those gloriously impossible decisions that the judges are forced to give in an effort to get equity and justice out of the insane apex law.

I humbly beg to disagree with his honor, the judge, and through the medium of your valuable journal to offer a solution that should reverse the former decision on all true and logical grounds, as follows:

(1) That whereas title is dependent on the apexing within the claims, and whereas the present vein or veins do not apex on the present surface, a former geologic surface being assumed and admitted, therefore in all logic we must assume the geologic surface that existed when the veins did truly appear on the surface.

(2) That whereas by your evidence the veins are not a single saddle or anteline, but are two distinct veins, the one being probably more recent and having cut the other, and that they have therefore at some time both apexed at a geologic surface of greater elevation than the present; then it is clear that on the upward dip the vein DB apexed in the Jim Butler ground, and the vein CB apexed in the MacNamara ground, and the West End had no vein and no apex at all.

(3) Now therefore be it decided in all justice and equity that the vein within the MacNamara ground and downward to the centre of the earth belongs to the Jim Butler, and conversely the vein in the Jim Butler belongs to the MacNamara; and the West End having no right and title and no mine, shall pay to me a sum equal

to the value of ore already extracted as due and just compensation for my expert advice in the matter.

JOHN M. NICOL.

San Francisco, August 7.

The Mexican Tangle

The Editor:

Sir—Touching on Mexico again, a subject that seems to occupy all minds, I desire to discuss briefly an aspect of the problem that seems to occur to few, and certainly not to the many peace-at-any-price people I am amazed to meet here on this Coast, where they harp so much on that chimerical phantom, the Japanese peril. They say: "Why should the United States mix up in Mexican affairs, etc.?" No one wants the United States to intervene, much less, go to war with Mexico; and we who have all to lose and nothing to gain by such a course, desire it least of all.

By "We," I mean all foreigners who reside in Mexico and are carrying on the many industries that represent over two-thirds of the capital invested in that country. We have nothing against Mexico nor its people. We do not wish nor ask for intervention or war, although many of us fear that due to the omissions of the past five years, only the firmest, most honest, and most diplomatic endeavor can evade the former. We cede the right to the Mexicans to murder and rob each other to the point of extermination, if they so see fit; and we readily grant the contention that the American government should in no way mix up in Mexican politics, and certainly its citizens should not. But has Mexico no obligations to foreigners? Has the foreigner no rights under existing treaties?

Mexicans may have the right to ruin their own country, to murder and rob each other and to destroy the property of their own nationals; but when, in working their own sweet will in Mexico, they murder the foreigner and rob him, and by their acts ruin his property, destroying, and jeopardizing foreign interests that have been induced to go to that country under treaty guarantees, has the foreigner no right to expect protection from his government? Has his government no obligation to give him that protection? Has his government no right to demand that protection? These are the questions.

E. A. H. TAYS.

Berkeley, August 9.

The American Boy and the Mine

The Editor:

Sir—Mr. Burch's article in your issue of May 13 senses a fact which is becoming very evident throughout the mining regions. The good Cornishmen and the sturdy Irishmen are not sufficient in number to go around, in the increasing operations of this country, and many other nationalities are now employed.

The chief trouble with the workmen from central

Europe is their lack of experience in mining operations, their lack of knowledge of the language, the difficulty in making them comprehend and do efficient work. The fact that these workmen are liable to be fewer in number for several years to come, offers a chance for American young men in a business which is both attractive and remunerative.

Mining work has appealed to few of our young men, as it has necessarily meant hard manual work for which they, with their better education, usually consider themselves superior. The increasing efficiency of mining operations and the larger amount of work done by mechanical means now gives a better field for the intelligence of the educated American. There has been, and is now, better opportunity for young men in mining than ever before, and better than in many other occupations.

The mining companies employ a good class of workmen, but would find it to their advantage to follow the lines suggested by Mr. Burch and give them instruction, in order to make them more efficient. This is already being done to some degree in the weekly and monthly conferences that the larger mining companies arrange with their foremen and shift-bosses for the safety and efficiency of the men. Still better results would ensue if this scheme were enlarged so as to give general instructions to the men employed in the mine, and both officials and workmen would find it to their mutual advantage to have such courses arranged. Undoubtedly assistance could be given by members of the staff of scientific institutions, if available, in the vicinity, to assist and broaden the work.

A noticeable example in this line is that of the Cleveland-Cliffs company of Ishpeming, where a technical man of experience is giving instruction to the employees. This is helping the workmen in a very laudable and very decided manner and bettering both their operations and the community. Many mines, as well as other industries, have tried to get along with as few foremen and officials as possible. This error has been realized and is being overcome by the appointment of efficiency-engineers whose work, at times, necessarily conflicts or runs on the same lines with that of the foreman. It would be better if foremen and shift-bosses were increased in number and efficiency themselves, and gave more time to individual men. The Newport mine, in Michigan, one of the best managed large producers in the iron region, divides the mine into districts with 30 to 50 men each. The boss of each district and each of the men receive, besides their wages, an additional amount per ton hoisted, each day's work and the amount gained being made known the next morning. This gives a zest and emulation among all hands and the operations always have the close supervision and help of the district-boss.

The training that Mexicans have received from Americans in mining operations, in mechanical and metallurgical work, has enabled many of them to occupy positions of importance in that country and to do work for which it had been necessary to employ foreigners in the earlier operations that outside companies had undertaken. It

is worthy of note that, generally, throughout the Republic, the population of mining towns has not taken part in this fratricidal revolution, but has always been anxious to work.

Inasmuch as this country is anxious to have good workmen for its industries and accepts all classes from outside countries, it is certainly to the advantage of operators to train men in efficiency and in citizenship. If it be known to American young men that such training gives them opportunity to learn a business that is interesting, healthy, and remunerative, particularly with the more efficient methods now applied, more applications for employment will be received from them.

Mining operations nowadays depend, not only on a strong arm, but quite as much on some knowledge of ore, on the intelligent handling and care of drills and other mechanical appliances, and on adaptation in breaking and handling various kinds of ground. American young men have an advantage over their fellow-citizens fresh from other lands, and practical knowledge of mining operations gives them opportunity to be placed in charge of men, if they display energy and intelligence. It is too true that American miners have, in recent years, been in disfavor in the mines of California and other States, but there are examples of good material left to their own wandering devices, without just this interest in their welfare and training that Mr. Burch suggests.

ROBERT M. RAYMOND.

San Francisco, August 11.

Stamp v. Ball-Mill

The Editor:

Sir—The closing sentence of your charmingly unbiased criticism of stamps and ball-mills carries by implication a further criticism of milling practice on its psychologic side. You refer to the selection of machinery "in accordance with the spirit of the times; not stamps, but ball-mills." In other words, fashion affects the equipment of the milling-plant as well as dictating the cut of the coat and the shape of the hat that the manager wears.

Many will remember the days when the weight of the stamp began to grow. From a standard of 750 pounds it crept up to 850, to 1000, to 1250, and even higher. The manager of a small plant, where experimentation was out of the question, specified the heavy stamp, merely because it was in the spirit of the time. Then the higher weights lost favor, until the 950 to 1000-lb. stamp became standard. That meant simply that wide experience had shown this weight to give superior average results. It did not mean that it was best for every ore. No general rule can apply exactly. Many a mill is pounding away with 1000-lb. stamps upon ore that would yield better extraction if crushed with lighter, or perhaps with heavier, stamps. The difficulty is to find opportunity to test what conditions best suit any particular ore. Only large and wealthy corporations are accustomed to do this. The smaller and weaker concerns follow the fashion, assuming the prevailing practice to represent the

wisdom expressed in the law of averages. The same thing applies to the relative efficiency of stamps and ball-mills. The manager who follows the fashion is less open to criticism, even though he may obtain an economic result inferior to that which might be reached after careful experimentation. Capitalists usually expect an engineer to assume an attitude of infallibility in deciding upon a line of treatment. The suggestion of experimentation is received as an indication of weakness. Only those who have made a business of mining appreciate the superior understanding of him who regards the rules of the text-book and of current practice as expressing merely general principles which must be modified to fit special cases. In the hurry to begin production it may be safer to follow the fashion, but many a plant would soon demonstrate a financial gain by including in the design a flexible unit where the problems presented by the particular ore under treatment could be worked out at leisure.

No one can deny the greater economy of power in crushing by ball-mills instead of by stamps. If the extraction maintains a high average also, the ball-mill becomes fully vindicated in that instance.

No two ores will crush precisely alike, although the tendency to give similar screening-curves is pronounced when the crushing conditions are the same. Departure from this general principle depends upon the greater tendency of certain minerals to generate colloids in wet grinding. If the ores are crushed dry, and contain less than about 2% moisture, the curves will be nearly identical. Variation in the curve is obtained chiefly by changing the conditions of crushing. Therefore a direct comparison between two appliances so widely different as stamps and ball-mills is of no great value, so far as interpretation of screening-curves is concerned. It is a question as to the treatment that is to follow, and as to which pulp will yield the higher extraction.

The stamp produces fine stuff; it also produces slime, but not by any means as large a proportion as the ball-mill. Engineers are not in agreement concerning the relative degree of comminution effected in a ball-mill by shock and by abrasion. A third principle is also active: particles gripped by neighboring balls or pebbles are crushed in the same manner as in rolls. The probability is strong that far more crushing is due to this than to shock.

In the case of the stamp, the major effect is that of fine comminution due to rupture of the particles induced by what may be called the reaction from the die. An ore-particle upon which the stamp drops is first compressed. A series of compressive waves is consequently transmitted through the mass. On reaching the die these waves are reflected upward, and meeting the on-coming initial compressive waves overcome the cohesion of the mass, and fine comminution results. This takes place close to the die. The upper portion of the particle is more coarsely fractured. A fuller account of experimental data on this point, which I obtained some years ago, is quoted by Robert Richards in his treatise on 'Ore Dressing' (Vol. III, p. 1330). The result, then, is to

produce fine, not slime, except in so far as colloidalization occurs.

In the ball-mill the comminution, so far as produced by shock and radial crushing (as in rolls, *vide* Richards, *loc. cit.*) will also be granular, though very fine, but, to the extent that abrasion occurs, the tendency to sliming, both by flouring and by colloidalization, is enormously in excess of any similar effect yielded in stamp-milling.

The practical point to establish, therefore, is whether there be any gain in extraction. If very fine grinding be essential for releasing the metal to the attack of solvents, the ball-mill wins. If moderately fine comminution be sufficient, then the balance must be struck between the higher power-consumption in stamping and the lower extraction from a pulp presenting the difficulties due to high colloidal content. The latter difficulties are evidently threefold: protection of metal in colloidal envelopes, interference with free filtration, and adsorption of bases from the ionized solution, affecting both the dissolved metal and the base in the original solvent. Dry-grinding of ore containing not above 2% moisture will, of course, reduce colloidalization to a minimum, but drying costs money, and can be reckoned economical only in the face of a demonstrated increase in extraction sufficient to pay a material profit on that operation.

Crushing devices that utilize the principle of abrasion sometimes present peculiar phenomena. An illustration will best indicate my meaning. While making tests of material for cement manufacture I had to deal with a limestone which had been formed as a beach deposit in Tertiary time. It was essentially a mass of consolidated shell-débris, with many shells still quite perfect and retaining the naere as lustrous as when it had been washed by the ancient tide. From time to time floods had evidently invaded the lagoon and had carried silt to the lime-beds, which, however, introduced no technical difficulty; but what appeared more serious was the fact that these thin layers of silt often contained quartz-sand in considerable quantity. Chemically the limestone, although rather high in alumina and silica, would make an ideal 'mix' with limy clays available in the neighborhood. The question was whether the flouring of this free silica would prove too expensive by prolonging the time of grinding, thus adding a prohibitive power-cost. After the first charge had been treated in the tube-mill, I was shocked to see the large amount of granular material remaining in my testing-sieve. A gleam of mother-of-pearl, however, gave a hint of the truth. The residue was soluble in cold hydrochloric acid. The quartz grains had been successfully floured, but the shell-naere, which seemed relatively so soft, had resisted abrasion the longer. Similar peculiarities are displayed by many gangue-minerals in ores which one would expect to be readily reduced to fine.

COURTENAY DE KALB.

Tucson, August 22.

GOLD received at the San Francisco Mint during July totaled 260,425 fine oz., and 191,383 oz. of silver. There was no coinage on account of the annual settlement. The vaults contain \$370,535,105.84.

Molecular Forces and Flotation

By Will H. Coghill

The warning about young men specializing in flotation, as sounded by E. P. Mathewson in a recent number of the PRESS, should be considered by all who are directing these men in their education. It provokes the question that ever confronts the instructor in a technical school.

The student may be drilled on the design and construction of the various flotation machines, and the methods and results of the experimenters, and be sent into the field feeling that he is strictly up-to-date, but his school-work would not amount to much if he has been taught only the ever-changing art. He would have acquired something more enduring and be better prepared to benefit from his college course had he been taught natural laws with enough of the art to give a view of the field to which the laws could be applied, for man's methods are ever changing while Nature's laws are invariable. The processes of a few years ago are now obsolete, but the principles upon which they were founded will be applied to new methods for generations to come.

To the workers in flotation has fallen the problem of outlining the rudiments, and then by means of laboratory experiment, made by aid of the results of workers in the related sciences, develop flotation to the point where scientific reasoning may be applied to direct tests on ores as is now done in cyanidation. It took twenty years to develop the science of the cyanide process. It will take as long in flotation if we continue our antiquated methods. So far as I can learn, not more than two of the great number of recent contributors of articles on flotation have had an opportunity for a deliberate study of the related sciences. The rest of us have a job to look after and are busy enough attending to it. Advancement is, therefore, slow. The papers by O. C. Ralston and E. E. Free are, of course, excellent. But in many cases they shoot above our heads; for this we and not they are to blame.

The majority of the workers in flotation who have had the advantage of a school of mines training have taken only the prescribed four years and then hurried into the business of mining. Their love for science was none too great when they left school and the constant employment in the art has in no way tended to increase it. By a careful reading of the articles mentioned they might hope to glean some fact, the knowledge of which would be of aid in the art of metallurgy, but the material is entirely too heavy for one who has not had a special training in science.

We should learn to think—not parrot the statements of others—in terms of the molecule before science will be of aid to us in flotation. We cannot adjust ourselves to this in a moment. It requires time and effort. Many of us have sat aglance while an astronomer spoke of distances

in terms of the diameter of the earth. We must now go to the other extreme and become familiar with molecular dimensions. This requires much study, but in it we acquaint ourselves with the observations of physicists and chemists so that we are not likely to spend valuable time in discovering something that is already known.

The mastery of science is not easy. While in school we had to learn the chapters page by page, but this does not seem to be the best way for those without an instructor. To advise one to go through a book rapidly, gathering only an idea here and there, and through it again, may seem to be superficial. But the aim is to master the subject and this is doubtless the way to do it. This method of study is endorsed by Dr. V. H. Gottschalk¹ when he says: "After several readings of the short paper on * * *, read first the excellent summaries at the end of * * * before undertaking a rapid survey of the whole set; follow this by a more careful consideration of the summaries with re-reading of portions of the text when necessary; continue this process until the drift of the argument begins to reveal itself."

One contributor has said that the scientific man has aided little in flotation. Indeed he is correct, and so is the old-timer who says that more mines have been discovered by simple prospectors than by mining engineers. The ratio of those who pursue the right methods to those who have no method at all is as 1:1000.

Have any of the big companies put their engineers on retainers so that they could review the fundamentals of science and pursue post-graduate work in a university where they could have access to a complete library? Probably none, because the American business man goes straight for the dollar and must see the wheels turning before he is assured of dividends.

Some of the blunders that have crept into the articles on flotation are a great drawback to those who wish to learn but find their library incomplete. One writer has said, for example, "the cohesion of water varies as the temperature * * * and at the boiling point there is no cohesion." This statement is misleading. Scientists had this problem pretty well in hand nearly a century ago and knew that surface tension became zero at the critical temperature and not at the boiling point, as we ordinarily use this term. Brunner² recognized this fact in 1847 and knew that sur. ten. decreases with rising temperature until the critical point is reached, when liquid and vapor become identical and sur. ten. is zero.

In the Smithsonian Physical Tables, the sur. ten. of

¹Bibliography, 'Concentrating Ores by Flotation,' University of Missouri.

²'Physical Chemistry,' Ramsey and Smiles.

water at 100° C. is given as 61.5, and nothing is said about boiling point.

Since critical temperature is so closely related to sur. ten. it is obvious that we shall acquire a working knowledge of it. At one time it was considered sufficient for us to be able to say that critical temperature was the temperature above which a gas could not be liquefied no matter how great the pressure. This served the purpose for which it was intended, but it is inadequate for us now. If we define it as the temperature at which the sur. ten. between a liquid and its vapor becomes equal to zero, and any meniscus or bounding surface disappears, we have added to our knowledge of molecular forces.

It follows that when liquids are near their critical point, for example, condensed gases, they will have small sur. ten., while liquids far removed from their critical point, such as molten metals and fused salts, will have large surface tensions.

Liquid carbon dioxide is an example of a liquid that is near its critical point at atmospheric temperature; the critical temperature is 31°C. Its sur. ten. is therefore very small unless artificial refrigeration is used.

Mercury, on the other hand, at atmospheric temperature, is so far below its critical point that it would be expected to have a great sur. ten. as indeed it has.

To aid further in getting the relation of critical temperature to sur. ten., I quote from Ferguson.³ He indicates their relation and the basis on which sur. ten. of liquids should be compared, saying: "In earlier researches on the subject, comparisons [of sur. ten.] were made at the same temperature, but it was recognized by Schiff that sur. ten. should be compared at corresponding temperatures, that is, at temperatures which are equal fractions of critical temperatures of the liquids under consideration." Continuing, we find him stating the relation of critical temperature to boiling point, thus: "Unfortunately the critical temperature of comparatively few organic compounds have been directly determined, and it was supposed that these conditions were fulfilled at the boiling point of the liquids examined. If this be the case the ratio of the boiling point to the critical temperature of all liquids should be the same where temperatures are measured on absolute scale."

The degree of exactness with which this condition is fulfilled is remarkable, as can be seen by an examination of tables published by Ferguson, also those in the 'Handbook of Chemistry and Physics,' and elsewhere. They show the value of this ratio calculated from a number of substances of very diverse boiling points.

An examination of these tables shows that it is a fairly accurate generalization to put

$$\text{Boiling point} = 0.656 \times \text{crit. temp.}$$

where temperatures are measured on the absolute scale; so that from the boiling point we can calculate the critical temperature (subject to an error of not more than 5% in the case of the carbon compounds). For a proof that vapors as well as liquids are regarded as having molec-

ular cohesion, one has only to refer to Van der Waals' modification of Boyle's law.

The toy-balloon theory⁴ that each molecule of water is drawn toward the centre of gravity of its mass cannot be taken as a substitute for the accepted theory of sur. ten., for it is not in accord with physicists either here or abroad. They generally agree that the radius of molecular attraction is insensible but finite. They are of one accord in the opinion that "every molecule⁵ attracts every other molecule that may happen to be within a certain distance from it, which we denote as the sphere of molecular attraction. In the body of the liquid, this attractive force is more or less neutralized by the fact that the molecule we are considering is surrounded on all sides by others, all pulling in different directions. Hence the combined effect is practically zero. At the surface, however, all the molecules are below it, and there are none above to neutralize the force they exert. There is thus a strong downward force tending to drag the molecule into the surface. This force makes itself manifest in the phenomenon known as 'surface tension' or 'capillarity.'

Methods of ore-dressing today fall under one of two heads, gravitation or flotation. The fundamental law of the former was discovered by Archimedes, that of the latter by Leslie. Archimedes, as we know, while in his bath, noticed the loss of weight of his own body and it occurred to him that any body immersed in a liquid must lose a weight equal to the weight of the liquid displaced. Leslie, a British scientist, was the first (1802) to give a correct explanation of the rise of a liquid in a tube.⁶ Archimedes considered only the force of gravity on known masses; Leslie took into account the molecular force. It is Archimedes v. Leslie. Metallurgists have written much on Archimedes' law and very little on Leslie's, the latter having been left to the physicist and chemist.

It is surprising how little attention metallurgists have given to the application of the physical principle discovered by Leslie. Until recently they have been quite satisfied to call it 'capillarity' and let it pass. Capillarity has made itself manifest to us in many ways. Richards speaks of it in his 'Textbook of Ore Dressing' under the subject of amalgamation. He says that the capillarity of mercury is negative except with those metals with which it easily amalgamates; and the trouble due to grease is familiar to mill-men. In cupellation, the lead oxide is drawn into the pores of the cupel, while the lead ignores them and tends to shape itself into a sphere. Were it not for molecular cohesion the resulting silver bead would flatten and become so contaminated by the cupel that its subsequent treatment would be difficult. Galena⁷ penetrates the fire-brick of the furnaces in which it is treated. Often a network of small veins of bright crystalline galena is found in furnace linings. The

⁵Some authorities state that Laplace first developed, about 1807, a theory of capillary action.

⁶'Metallurgy of Lead,' Hoffman. P. 8.

molecular deportment of galena and litharge is quite different from that of lead itself.

In zinc smelting it is necessary to re-work the 'blue powder' because the film of oxide,⁸ which coats each particle of zinc, prevents coalescence. The forces that control the films on blister-steel and blister-copper are identical with those that maintain the form of the soap-bubble.

The geologist has studied the bubbles in lava and has found that the vesicles⁹ are roughly spherical. This spherical shape cannot be maintained unless the pressure on the inside is greater than that without. Only surten, can account for this excess. He is also aware that if the wick of a lamp touches water,¹⁰ the latter rises through the capillaries previously filled with oil, makes the flame sputter, and often extinguishes the light. In the same way water will pass from the coarse spaces of sand or from fissures into the fine capillaries of shale, displacing the oil, which is thereby forced into the sand through neighboring pores. The cohesion that holds

FIG. 1.

FIG. 2.

FIG. 3.

FIG. 4.

FIG. 5.

FIG. 6.

together the particles of a crayon and adhesion of the chalk to the blackboard, or of dust to a mirror, are all evidence of molecular force. Many of the examples cited come under 'capillarity,' but since that is difficult to define and is therefore likely to be used to cloak ignorance, I shall not attempt a definition. Molecular cohesion and adhesion, and probably molecular repulsion, must be studied in detail.

A study of capillarity is of great aid in gaining a conception of the conduct of the molecular forces of cohesion and adhesion that cause some substances to float on the surface of a liquid while others sink. I quote from a high-school book on physics,¹¹ which to my mind, gives one of the first lessons in the science of flotation. The discussion is as follows: "We must keep in mind two familiar facts: first, that the surface of a body of water at rest, for example a pond, is at right angles to the resultant force, that is, gravity, which acts upon it; second, that the force of gravity acting on a minute amount of liquid is negligible in comparison with its own cohesive force. Consider then a very small body of liquid close to the point *O* (Fig. 1) where water is in contact with the wall of the glass tube. Let the quantity of liquid con-

sidered be so minute that the force of gravity acting upon it may be disregarded. The force of adhesion of the wall will pull the liquid particles at *O* in the direction of *OE*. The force of cohesion of the liquid will pull these same particles in the direction of *OF*. The resultant of these two pulls on the liquid at *O* will then be represented by *OR* (Fig. 1). If then the adhesive force *OE* exceeds the cohesive force *OF*, the direction of *OR* of the resultant force will lie to the left of the vertical *OM* (Fig. 2) in which case, since the surface of the liquid always assumes a position at right angles to the resultant force, it must rise up against the wall as water does against glass. If the cohesive force *OF* (Fig. 3) is strong in comparison with the adhesive force *OE*, the resultant *OR* will fall to the right of the vertical, in which case the liquid must be depressed about *O*. Whether then, a liquid will rise against a solid wall or be depressed by it will depend only on the relative strengths of the adhesion of the wall for the liquid and the cohesion of the liquid for itself. Since mercury does not wet glass¹² we

know that cohesion is here relatively strong, and we should expect, therefore, that the mercury would be depressed, as indeed we find it to be. The fact that water will wet glass indicates that if this case adhesion is relatively strong, and hence we should expect water to rise against the walls of the containing vessel, as in fact it does. As soon as the curvatures just mentioned are produced, the concave surface *aob* (Fig. 4) tends, by virtue of surface tension, to straighten out into a flat surface *ao'b*. But it no sooner begins to straighten out than adhesion again elevates it at the edges. It will be seen, therefore, that the liquid must continue to rise in the tube until the weight of the volume lifted balances the tendency of the surface to flatten out. Similarly a convex surface *aob* (Fig. 5) falls until the upward pressure at *o* balances the tendency of the surface *aob* to flatten out."

If, in the case of water against glass, the water is pulled upward and in the case of mercury against glass the mercury is pulled downward, the converse must also be true, namely, that in the former the glass is pulled down and in the latter the glass is pushed up.

Now assume that you had two minerals so that they are partly submerged by a liquid and that with one adhesion is very great (relatively) and that with the other the adhesion is very slight. It is obvious that the

¹¹'A First Course in Physics,' Millikan and Gale.

¹²It is a well known fact that there is a slight adhesive force between mercury and glass and that mercury exerts an attractive force upon air, but the quotation suffices for the present.

surface of the liquid will turn up at the contact with the former and down and around the other, and that if these particles are so small that the force of gravity is negligible it is impossible for the former to float and just as impossible for the latter to sink. One of them cannot ride on the surface and is actually drawn into the liquid like gold into mercury, while the other cannot by any means enter the liquid unless its mass is sufficient to overcome the contractile force in the surface of the depressed liquid.

This process of reasoning is what I consider to be a natural and correct result of the study of the cause of capillary rise and depression as presented by Millikan and Gale, and to show that my conclusions are in harmony with their ideas I quote them again, where they discuss the floating of a needle. They say: "So long as the needle is so small that its own weight is no greater than the upward force exerted upon it by the tendency of the depressed liquid surface to straighten out into a flat surface, the needle could not sink in the liquid, no matter how great its density. If the water had wet the needle, that is, if it had risen about the needle instead of being depressed, the tendency of the liquid surface to flatten out would have pulled it down into the liquid instead of forcing it upward. Any body about which the liquid is depressed will therefore float on the surface of the liquid if its mass is not too great."

If the needle floats, the surface is turned downward, as in Fig. 3, where the resultant of the parallelogram of adhesive and cohesive forces lies in the liquid; and if it sinks, the surface is turned up, as in Fig. 2, where the resultant lies in the solid. Therefore, may we not say that if we can draw the resultant of the forces of cohesion and adhesion when a mineral is in contact with water, we can predict whether or not it is floatable; for if the resultant lies in the liquid (Fig. 3) it will float, and if it lies in the mineral (Fig. 2) it will sink.

We note next that when water is in contact with quartz the resultant lies in the solid; when it is in contact with galena¹³ the resultant lies in the liquid. We can, therefore, separate galena from quartz by flotation. I believe it to be quite possible for us to use a contaminating substance in the water and thus vary the molecular attractive forces so that with some sulphides the resultant lies in the liquid and with other sulphides it lies in the solid. This, indeed, has been done, and I believe that this idea is essential to the understanding of selective and differential flotation. To be sure, the introduction of the parallelogram of forces is only a shift from one series of unknowns to another, but it affords a means of stating the problem accurately, which is the first step in a solution.

The reader here exclaims: "Oh well, you are talking about film-flotation?" I think that anyone who will give serious thought to the above demonstration of capillary rise and depression will be convinced that there is

nothing but film-flotation.¹⁴ All flotation depends upon the film. If a piece of sulphide is brought to the surface by a bubble, it is, indeed, riding on the wall of a hole in the water, the only difference between this and what is commonly meant by film-flotation being that the hole is a sphere with finite radius while in 'film-flotation' the surface of the wall has an infinite radius.

If this is true, we go too far afield when we marshal osmosis, new-born gas, static charges, etc., for a first lesson in flotation.

Many writers have expressed a desire to discover the nature of the forces that cause a sulphide particle to cling to a bubble. I think their desire will never be appeased, for there is no such adherence, except insofar as there is a slight adhesion of the liquid film to the mineral as it rides in the cavity in contact with the wall or on a plane surface. With this exception, a bubble does not cling to a sulphide particle in a flotation-cell any more than butter clings to our fingers when we carry a pound of it from the store.

What has been observed, and not properly interpreted, is the coalescence of two cavities, one of which is filled with mineral and the other with air, where the mineral is brought to rest on the wall of the resulting cavity or, perchance, the walls of the two cavities do not break through but merely cling together.

A piece of submerged galena is just as surely surrounded by a sur. ten. liquid film as is the air-bubble or submerged greased needle. If this is not plain look again at the familiar cross-section of the floating needle, Fig. 6. That the film extends below the needle there is no question, and it is just as sure that if the needle were submerged the film would surround it. It is obvious that any submerged solid is surrounded with a liquid film when the resultant lies in the liquid, for this resultant represents an inward drawing of the molecules that causes the contractile force known as surface tension.

If a piece of quartz impinges against the wall of one of these cavities and has not sufficient kinetic energy to carry it through, as a bullet pierces a thin board, the rise of the liquid about it and the contractile drawing of sur. ten. will cause it to retreat directly into the liquid just as surely as the glass tube in Fig. 4 is pulled into the water. If it has sufficient energy, so that it can pierce the wall where it first impinges and falls on the wall in another place, it will likewise be cast out of the cavity. When a piece of galena hits the wall the conditions are entirely different; for the galena fills a cavity that has walls just like those of the bubble and what happens is nothing more or less than the coalescence of two bubbles. If the impact is very slight they might only cohere, and thus give the appearance of a mineral grain clinging to the bubble, when in fact it is the bag about the mineral that has become attached.

It is commonly accepted that a hole in water filled with air is encased in a sur. ten. film; by applying the prin-

¹³Galena and quartz are here supposed to be in such condition that they are typical of floatable and non-floatable minerals.

¹⁴This statement applies to the processes now in operation, not the original bulk-oil method of Elmore.

ciples set forth by Millikan and Gale one sees that a similar encasing film exists when the hole is filled with either a greased needle or galena. In the first case there is a wall of air; in the second, a wall of grease; and in the third, a wall of galena.¹⁵ In every case the resultant of cohesion and adhesion is such that it lies in the liquid. A piece of glass submerged in mercury would be surrounded by an extremely strong film. If glass is submerged in water there is no sur. ten. liquid film.

I have cited an instance where there is no liquid encasing film at all (glass-water interface) and one where the film is excessively strong (glass-mercury interface). May not these extremes be plotted and connected by a continuous curve with points to show the tension at the solid-liquid interface of various combinations of substances? Yes, and more than that. One end of the curve might represent great sur. ten. in the surface of the solid and the other end a great sur. ten. in the sur-

Fig. 6a.

face of the liquid. Fig. 6a is a diagrammatic sketch to show this. The sur. ten. of the glass-water interface, where the resultant—and therefore the sur. ten.—is in the solid, is placed at one end and the curve passes through a zero sur. ten. to an extreme point representing tension at the glass-mercury interface.

If the resultant lies in the solid there is no liquid film, but, instead, a sur. ten. solid film, and the sur. ten. would plot on *ao* in the quadrant *xoz*; while if the resultant is in the liquid there is a liquid film and the sur. ten. would be indicated by a point on *ob* in the quadrant *woy*. It seems to me obvious that the non-floatative minerals would plot to the left and the floatative minerals to the right of *zw*, and that such minerals as fluorite, garnet, and calcite, which have been described as at times inclined to float, would be placed very near *zw*.

Since I have said so much about the encasing sur. ten. film, it might be well to see if the workers in colloid chemistry take cognizance of this sort of thing. Indeed, we find that there is no lack of precedents. The idea of films around small particles has long since been accepted, and furthermore, before the Wilfley table was invented, they knew that it was the coalescence of these films that caused aggregation. I quote from 'Colloid Chemistry' by Ostwald, page 88: "Stress was laid upon the importance of these envelopes in phenomena of condensation early in the history of colloid chemistry. This, J. M. van Bemmelen wrote in 1888: 'I think it possible that

the formation of the flakes which are precipitated in a liquid is dependent upon a change in the surface tension of the liquid membranes surrounding the colloid particles, of such type that these membranes between the particles are torn at some point, thus permitting the particles to form aggregates.'"

This excellent picture of aggregation tempts me to quote more of Ostwald's text, but we must leave it and finish the high-school book before taking up a more advanced work. In doing this let us make some simple tests. Touch the round end of a glass rod to the surface of water. No sooner does the smallest physical point come in contact with the water than the water seems to jump to the rod and spread over the end as if it were magnetized. We say, that is to be expected, that is capillary rise. Observing that there must be a great pressure exerted upon the film that is pulled to the glass rod with such manifest energy, we explain the spreading and consequent rise in the terms of John Leslie, who, in 1802, said: "The result of this pressure if unopposed is to cause this stratum to spread itself over the surface of the solid as a drop of water is observed to do when placed on a clean horizontal glass plate; and this even when gravity opposes the action, as when the drop is placed on the under surface of the plate."

Since this plain and simple reasoning of Leslie's is credited by Clerk-Maxwell as being a correct explanation of the rise of a liquid in a tube and further, since it leads us to the same conclusions as does the 'component and resultant' method of Millikan and Gale, we feel an added security and proceed with a similar test using a different solid substance. Let us take for this test a fragment of galena and touch it gently to the surface of the water. Does a dimple appear immediately to indicate the presence of a membrane that is resisting rupture? Not so. The water jumps to the galena much as it did to the quartz, though probably not so vigorously. We argue that this is not in accordance with our expectations; thereupon we repeat the test and make sketches.

Fig. 7.

Fig. 8.

Fig. 7 shows how the surface of the water is elevated to wet the glass rod, and Fig. 8 shows much the same sort of phenomenon when galena is used. Though badly confused, we decide to carry the test one step farther. To do this, press the end of the glass rod below the natural surface of the liquid and also allow the galena to float. Fig. 9 and 10 show a cross-section through the contact of liquid and the two solids.

The liquid is now plainly elevated around the rod and depressed around the galena. This seems perfectly natural and satisfactory; but how about the rise of the liquid in Fig. 8 where galena seemed to be wetted? It

¹⁵Whether or not galena be surrounded by a film of adsorbed air or grease does not concern us now.

is nothing more nor less than adhesion, a component that must be reckoned with, however small it may be, as, for example, in Fig. 3, where mercury is in contact with glass. Let us prove that there is adhesion between mercury and glass. To do this we will take some mercury in a watch-glass and use the same glass rod. If we watch

Fig. 9.

Fig. 10.

closely, as we lower the rod to meet the mercury, we can see that the mercury rises a little around the end of the rod at the instant they come in contact. See Fig. 11. Upon pulling the rod away it is plainly seen that there is adherence. Having performed this experiment we may go into the mineralogy laboratory with a beaker of water and find that any one of a dozen minerals taken at random adheres more or less firmly to water. In some cases, when the mineral is pressed below the surface we can detect capillary rise and in others a depression.

Then what does our popular term 'wetting' mean? It can mean nothing more than absence of repulsion unless we give it a special definition, as some physicists have done. As for the spreading, Leslie, the sage of more than a century ago, in speaking of adhesion of a liquid to a

Fig. 11.

Fig. 13.

solid as indicated in Fig. 7, 8, and 11, said: "the result of this pressure, if unopposed, will cause the liquid to spread." When the adhesive force is sufficiently in excess of the cohesive force the liquid will spread indefinitely, regardless of gravity, until the thickness is such that it could only be measured in terms of the diameter of a molecule. If the solid body attracts the liquid strongly enough it will draw every particle of it as near as possible to itself. Thus it is that a liquid spreads over certain clean surfaces. But such perfectly clean surfaces¹⁶ are difficult to obtain and that on account of this very phenomenon. Thus, the least drop of oil touching a glass surface spreads over it quickly and completely changes the effect of adding a drop of water. Such department needs no emphasis to impress those interested in the laws relating to flotation.

The spreading of a group of molecules of water within

the radius of molecular activity of the glass is analogous to the spreading of a ball of soft putty while resting on a plane surface. In both cases the distortion is due to attraction; in the first, the attraction is called molecular; in the second, gravitational.

But analogies do not satisfy us; we are seeking the foundation of a new and important science, and there will be opportunities for analogies later. Leslie said "if unopposed." We shall do well to deal with components and not generalities. We are reminded therefore how we stated above that in some cases, when the mineral was pressed below the natural surface of the water, we could detect capillary rise and with other minerals a depression. This statement must be considered with caution lest we let important facts slip our attention.

Look again at Fig. 4 and 5. Shall we agree that in contact with a perfectly clean piece of glass the surface of water always turns up and that of mercury always turns down? You say, Yes; that has been proved. Not so; and here, as has often been our experience we find that we have to unlearn what we have once learned. Let us place a glass rod in mercury so that it will rest in a position, not vertical as in Fig. 5, but in an inclined

Fig. 12.

position, and draw the components of adhesion and cohesion and their resultant. See Fig. 12.

Now we know that the surface of a liquid tends to adjust itself at right angles to the resultant of the forces acting upon it and that if gravity predominates the surface is horizontal. But let us consider a group of molecules at O so small that the molecular forces predominate over gravitational forces. We have the force of adhesion OE acting at right angles to the surface of the glass and pulling the molecules to it and the cohesion of the liquid pulling these same particles in the direction of OF . The resultant of these two forces, OR , is the force to which the surface assumes a position at right angles, and since OR lies to the left of a vertical line through O it is apparent that the surface of the mercury must turn up to meet the glass. In like manner it can be shown that the mercury turns down to meet the glass at O' . Since the mercury turns down at O in Fig. 3 and up at the same contact in Fig. 12, it is obvious that there is a slope of the glass at which the mercury would stand level. It may seem bold to draw these components so freely when so little is known of their absolute value. It must be said in explanation that they are only diagrammatic and that is all that Milligan and Gale intended. It is a fact, however, subject to a simple ocular demonstration, that mercury does turn up to meet the glass at O and down at O' Fig. 12. The point to be

¹⁶Mechanics, Molecular Physics, and Heat. Millikan.

made is that in both cases the resultant lies in the mercury, even though the mercury turns up to meet the glass as does water against glass where the resultant lies in the solid, and that the slope of the liquid contact must be considered only in connection with the angle at which the mineral meets the original surface of the liquid. The elevation of the mercury at *O* does not mean that the sum-total of all the forces tends to pull the glass down as does water pull the glass in Fig. 4, for we must remember that the film of mercury extends entirely around and under the glass and that it tends to contract and reduce its distorted sur. ten. film to a minimum. It will therefore push the glass upward if the downward component due to weight of the glass is less than the upward component due to the contractile force of the liquid.¹⁷ Briefly stated, an upturned liquid does not always indicate that the resultant turns into the solid as one would conclude from a study of Fig. 2. By the purely theoretical treatment of components adopted in Fig. 12, one can show that the surface of water also may well be approximately horizontal when in contact with glass.

After reaching these conclusions by merely "reading between the lines" of a most elementary physics and checking them by laboratory tests, it is interesting to note that a more advanced text-book¹⁸ gives further corroboration in the recitation of a "test to determine the angle of contact of mercury with glass."

An inverted spherical flask, as shown in Fig. 13 is used. The quantity of mercury in the flask is adjusted until its surface in contact with the glass is horizontal.

Then $\frac{d}{2} = r \cos (\Theta - \frac{\pi}{2})$, where Θ is the angle of contact sought, d = diameter of circle of contact of mercury and glass, and r = radius of the spherical flask.

Likewise the surface of water would be about as shown by line *BB*. Contamination of the glass or liquid might well give surfaces that lie anywhere between the two mentioned. This might be called a reciprocal method for determining the angle of contact; for in this test the liquid surface is horizontal and the solid surface is inclined, while the angle of contact, as we are accustomed to thinking of it, appears with an inclined liquid surface against a vertical solid surface. The 'direct' position of

Fig. 11.

Fig. 13 appears in Fig. 14 where *AA* and *CC* are vertical. This shows the same angle of contact in a position more familiar to us.

The foregoing shows that it is insufficient to say that the liquid turns up or down. The angle of contact must be given; it is the same regardless of the slope of the

solid surface. For example, in Fig. 12 the angle of contact at *O* must be the same as at *O'* and again the same at *O* in Fig. 3. Again the actual angle of contact may be distorted by the weight of the mass as, when a drop of mercury rests on glass.

The question may well be repeated: Is it correct to speak of a sur. ten. film of mercury against glass, and if the term is correct, do we need added evidence that it does exist at the mercury-glass interface?

In our first conception of the film we thought only of the upper horizontal surface of a liquid, that is, the liquid-air interface of standing water. We then extended it to include the walls of a submerged air-bubble, and now the only rational application of film or membrane is to include also all interfaces where there is sur. ten. If there is a solid-liquid interface in which the resultant turns into the liquid, the membrane is in the liquid, and if the resultant turns into the solid, the membrane is in the solid. It is of the utmost importance that we add contaminating substances to the mill-water that will cause the membrane surrounding the grains of ore (sulphides) to be in the liquid and simultaneously cause the membrane around the gangue to be in the solid. Since the solid membrane is an intangible sort of a thing because it is solid, it is best to deal with its antithesis: the absence of a liquid membrane. It may well be said therefore that when the flotation metallurgist has contaminated his liquid so that there is a liquid membrane around the ore particles and none around the gangue, he has mastered the first step in his process.

The liquid film must not only surround the ore particles, but it must be of such a nature that it will rupture at the point of contact with an impinging air-bubble and thus cause coalescence; or if coalescence does not take place the films must cohere. This is the second step.

Reference to another simple and familiar physical experiment may be of service here to give added evidence that when mercury is in contact with glass the membrane is in the liquid—a state quite different from water in contact with glass—and aid in further acquainting us with laws second to none in their application to flotation, the laws of molecular cohesion and adhesion.

Take two conical capillary tubes, *a* and *b*, Fig. 15.

Fig. 15.

Place mercury in *a* and water in *b*. The mercury will at once run to the large end and the water as quickly to the small end of the respective tubes. The mercury will travel to the larger end of the tube even though it be slightly elevated. In doing so, it decreases its surface and finally reaches the point where the diameter of the tube is sufficient to allow it to assume the form of a sphere. Such conduct is possible only when a liquid is surrounded by a sur. ten. liquid membrane. Here, with the mercury, surface energy in the liquid, after its well-known manner, tends to reduce the amount of surface to

¹⁷Here the principle of Archimedes, namely, loss of weight due to displaced liquid, is not taken into account.

¹⁸'General Physics,' by Edser, p. 306.

a minimum. The same components exist in *b*, but they are of different magnitudes and are such that the liquid membrane is only at the liquid-air surface, and it is obvious that it is reduced by a movement toward the small end. The concave water membrane at the ends are similar to the piston of an hydraulic press, and the liquid is drawn in the direction of the greatest force per unit of area. If we assume that these concave surfaces are hemispherical it is obvious from the formula, $P = \frac{2T}{r}$ that the drawing forces per unit of area toward the ends are inversely as the radii. If the liquid film extended entirely around the water such an increase in total surface could not happen.

"At a solid liquid interface two cases are therefore possible—sur. ten. in the same sense as in the case of the gaseous bounding medium may appear or," according to Wilhelm Ostwald, "we may have a surface tension of the opposite character. In this the (liquid) surface does not tend to become as small as possible, and we say that the solid body is wet by the liquid. Mercury on glass is an example of the first; oil on glass, of the second. When the surface of a solid is wet by a liquid, it (the solid) acts like the surface of a liquid, and therefore seeks to become as small as possible."

At this point an analogy may be of value, not as a proof but as an aid in showing how the deportment of mineral grains in a flotation-cell might well depend on whether they are or are not surrounded by a liquid film.

In this hypothetical case, we grant first that it is a physical fact that glass submerged in mercury is encased in a liquid membrane; that this membrane is squeezing the glass in accordance with the formula $P = \frac{2T}{r}$, in the same manner as if air occupied the hole in the mercury in place of the glass. Second, let us remind ourselves of the great 'affinity' of mercury for gold. This affinity or capillarity¹⁹ is well known and one only needs to be reminded that gold is drawn into mercury²⁰ in the same manner as glass is drawn into water to see that they are perfectly co-ordinate.

We take a pulp composed of mercury, particles of gold, and crushed glass; we place it in a Callow cell and blow air through it. Can you conceive of the gold entering or even clinging to an air-bubble? No, you would not think of such a thing any more than you would of the gold in the amalgam on the copper plates mysteriously popping to the surface and parting company from the mercury. But, on the other hand, consider the glass. It is surrounded by a liquid membrane of mercury. If this membrane comes into contact with the membrane of an air-bubble and bursts at the junction, the glass will be squeezed out of its little sack into the large one and ride securely to the surface on the wall of

the resulting bubble. Thus the cell would produce an overflow of glass and an underflow of mercury with the gold. If we replace mercury with water, glass with galena, and gold with quartz, and adjust the detail by means of a contaminating substance, we afford a complete and perfect transfer from an hypothetical to an actual operating flotation-cell. Unfortunately, too many of us have concerned ourselves so much with detail—the contaminating substances, etc.—that we have failed to grasp the fundamental idea. Electrolytes, static charges, osmotic pressure, and much of the researches of recent workers in physical and colloid chemistry will all have their places in the science of flotation after the foundation has once been laid.

Archimedes was interested only in the mass per unit of volume, Leslie in the manner in which the molecular forces of a substance affected an unlike substance. Since the range of action of molecular forces is so very small it is obvious that only those molecules at the surface could be sufficiently close to another substance to affect it. We are interested, therefore, in the forces at the common surface of two substances. In this, our position is the same as that of the chemist. Bigelow²¹ says, "more and more we are realizing that the conditions in contact surfaces often play the decisive rôle in important processes."

I have tried to expose the fallacy that mineral particles adhere to impinging bubbles; as an alternative, I have advanced a theory involving coalescence, this being more in accord with scientific ideas.²² We are familiar with the coalescence of two soap-bubbles, but have much to learn concerning the coalescence of two films when one of them surrounds a solid. Here I would recommend a study of boiling in the volume on 'Heat' in the 'Text-Book of Physics' by Poynting and Thompson. It teaches that the bubbles which carry the steam to the surface of a liquid do not rise from points at random, but from definite points or particles of foreign matter that form a boundary of the liquid. There must be a nucleus in the shape of a minute bubble into which the steam passes. As evaporation proceeds, the bubble grows and finally breaks away, always leaving a small portion behind as a nucleus, just as part of the neck of a drop of water is left when the drop breaks off from a surface. Some substances carry a great many nuclei while others are barren. A beaker, thoroughly cleansed in hydrofluoric acid, is so barren of nuclei that water can be raised several degrees above the boiling point without boiling taking place. A piece of flint immersed in a liquid was alive with bubbles over its entire face until broken in two, when no steam was given off from the freshly formed surface. The introduction of iron filings caused rapid ebullition. Substances over which water is most reluctant to spread, that is, those solids which show the least adhesion for water, furnish the greatest number of nuclei. One paragraph from a paper by Lord Rayleigh,²² where he discusses 'Liberation of Gas

¹⁹In using 'affinity' and 'capillarity' I am only attempting to use terms that we have all used when discussing amalgamation.

²⁰Thomas T. Reed, Trans. A. I. M. E., Vol. 37, says that amalgamation is a physical rather than a chemical process; that the sur. ten. of mercury draws the gold beneath the surface.

²¹Theoretical and Physical Chemistry, p. 247.

²²Philosophical Magazine, Vol. 48, 1899.

from Super-saturated Solutions,' is sufficient to show the close relation between boiling and flotation. He says: "It seems to me that Tomlinson was substantially correct in attributing the activity of non-porous surfaces to imperfect adhesion. We have to consider in detail the course of events when a surface, for example, of glass, is introduced into the liquid. If the surface be clean, it is wetted by the water advancing over it, whether there be a film of air condensed upon it or not, and no gas is liberated from the liquid. But if the surface be greasy, even in a very slight degree, the behavior is different." In another book²³ we learn that "metal turnings depress the boiling point because their molecular attraction for water is less than that of glass."

We have ample evidence, therefore, that solids, like fresh quartz over which water spreads freely, do not carry nuclei of air, while solids like galena, over which water does not spread freely on account of adhesion, do have small bubbles attached to them while submerged in water. For an extreme case where air nuclei would be present, we might suppose a glass sphere to be submerged in mercury. As it passes below the surface with

which is inflated with air and expelled gas. I wish to express my gratitude to Dr. Joel H. Hildebrand for his critical reading of these notes and for his assistance during the seminar in 'Colloids and Surface Tension' at the University of California. Also I wish to thank H. M. Parks and Ira A. Williams of the Oregon School of Mines for their co-operation.

Explosives

Explosives as used in mines are discussed by E. M. Weston of Johannesburg, in his recent little book 'Practical Mining on the Rand.' This book was written for the purpose of explaining to shift-bosses and miners the things they should know about rock-drills, explosives, stoping, development, and similar subjects. The author is manager of a mine on the East Rand. Of so practical a description are the contents of the book that the Transvaal Chamber of Mines purchased 3000 copies for distribution among underground employees. The miner's work is dependent on the proper use of explosives, and if this is not understood, bad results are sure to follow. Explosives are of two kinds; slow or rending, such as gun-powder; and high or quick, such as dynamite. Gun-powder or black powder, when exploded, changes into gas in one-hundredth part of a second. One part of the powder makes 1500 to 2000 volumes of gas, and exerts a pressure of 11 tons per square inch of rock. On the Rand, high explosives are commonly used. They turn into gas much more quickly than black powder, taking only one twenty-thousandth to one fifty-thousandth part of a second. One volume of high explosive makes 16,000 volumes of gas, which exerts a pressure of 117 tons per square inch of rock. This is a force over 10 times more powerful than black powder. The high explosives include straight dynamite, gelatine dynamite, gelignite, and blasting gelatine. Nitro-glycerine forms the chief constituent of all four. It is a thin oily liquid, of specific gravity $1\frac{1}{2}$. Straight dynamite is nitro-glycerine absorbed in diatomaceous earth or some similar neutral base. Gelatine dynamite contains also nitro-cellulose with potassium nitrate, and wood-meal. It is 25% stronger than straight dynamite. Gelignite is a mixture of nitro-glycerine, nitro-cellulose, potassium nitrate, and sawdust. It is 12% more powerful than dynamite. Blasting gelatine contains about 93% nitro-glycerine, which forms a jelly by combination with an extract from gun-cotton. It is 50% stronger than dynamite. Nitro-glycerine begins to evaporate and exude from an explosive at 110° F. Any explosive in this condition is dangerous to handle, and should not be used, but destroyed. Frozen explosive should be thawed before using, as otherwise it will not detonate properly and is likely to explode from rough handling. When a man has been overcome by nitrous oxide gas resulting from an explosion, it is a mistake to carry him out at once. The first effort should be to reach the air-cock and turn on the air, or break the pipe with a hammer. The sufferer should be held in the escaping air, thus gaining time.

FIG. 16.

FIG. 17.

its angle of contact of 140° , it would appear as shown in Fig. 16.

With the disappearance of the waist at *a*, the film closes around an air nucleus. A small quantity of air would thus be carried down and if the mercury were transparent, one could see an air bubble attached to the glass. A fresh piece of glass in water would not do this, for the water would close over it as shown in Fig. 17. But we do not have to go so far afield to account for attached air-bubbles. The surface of all minerals contain depressions and it would be impossible for them to pass from air to water without some of the air residing in the depressions being carried below the surface. Whether or not the air is held in place depends on the adhesion of water and mineral. If adhesion is less than cohesion of the liquid molecules, the surface film will pass around the air nuclei and hold them in place, but if adhesion is great the water will spread over the entire surface of the mineral and ultimately release the air bubbles. The application of these principles to flotation is simple: minerals with the least adhesion for water will retain the greatest number of small bubbles; these bubbles are inflated by gases expelled from the solution; and finally an air-bubble in its passage impinges against, and coalesces with, the attached bubbles and the mineral is carried to the surface by the resulting bubble.

Buying Supplies for a Mine

By Nelson Dickerman

One of the most important problems for the management of mining enterprises in foreign countries is the proper maintenance of warehouse stocks. Supplies of all kinds that might be necessary and in sufficient quantity to meet every demand must be kept on hand. And these demands must be anticipated, often as much as six months, so as to have the goods on hand when needed. At the same time the management must not invest in supplies any more money than is absolutely necessary for this purpose, as this money is totally unproductive. Perhaps a few notes concerning my experiences in such matters while in Colombia will be of interest.

We could depend but little on the local market in Colombia and what supplies we got in the country were bought at such an advance in price over that of the same article from abroad, that we did only a small percentage of our trading there. Our nearest market was New York, and it took from three to four months from the writing of an order to the receiving of the material. Even by cabling, to which we sometimes resorted in case of great necessity, it took from a month to six or seven weeks to get the goods.

In ordering, it was very important to state precisely and accurately what we wanted, how it was to be packed, and how shipped. At this point I shall digress and state that the United States will never be able to supplant England and Germany to any large extent until exporting houses learn how to fill orders accurately, pack properly, mark packages in the language of the country to which they are consigned, and make out correct bills-of-lading and consular invoices. Many of the houses here think their duty to their foreign customers ends with the filling of the order and getting it off their hands. But unless the goods arrive in a satisfactory condition and with the least amount of expense and bother to their customers, they have failed in the performance; and this means a dissatisfied customer. Perhaps it will be well to run over the various phases of ordering and receiving supplies in the hope that there may be a point here and there that will help someone who is undertaking this duty for the first time under similar conditions.

Our warehouse and supplies were administered under as accurate and thorough a system as we would maintain at home. A card-index of supplies was carefully kept, and checked whenever possible. Any extraordinary demands were anticipated as far as possible by keeping in touch with the foremen of the different departments; in fact, it was only by the closest co-operation of all departments that we never had to shut-down for want of material or tools that we could not improvise on the ground.

The supply-man had to be more self-reliant than on a

similar job in the States. He endeavored to keep on hand a complete file of catalogues and descriptive matter. Frequently the need of some new tool or device would find him without the proper catalogue; or the need of some part of electrical or pump machinery that was not a common stock article would find him without proper descriptive matter. He could not order a thing on trial, as the customs and transportation charges would not permit the returning. Nor could he afford to take the chance that the people from whom he ordered would understand better than he did what was wanted. The chance of a mistake might mean the having to wait for the proper fulfillment of the order from four to six months. He had to be sure of what he was ordering and whether the article, if a new one, would be satisfactory under the peculiar climatic conditions. In sending an order it was necessary to give full directions for marking and shipping. And often after some particularly bad luck we would append packing directions to our next order or the correct way of making out consular declarations.

Under packing troubles we had a number of complaints to make. Here are a few as they recur to me. Under the custom duties of Colombia, the tax is not charged on the net weight of an article only but on the container and packing as well. We ordered a high-grade smoking tobacco from one of the largest distributing houses in New York, asking them to pack it as lightly as possible in tightly strapped boxes. This tobacco comes in half-pound vacuum-sealed tins. It was sent to us two tins each in heavy porcelain jars, the latter a generous gift, packed in a heavy wooden box. As tobacco pays one of the highest duties in Colombia, this tobacco, which retails here at \$2.25 per pound, cost us \$14.91 per pound to land in our store, and no one could afford to buy it. On several different orders we requested this same house to remove the heavy wooden caddy from chewing tobacco and wrap the tobacco in oiled paper, but they never complied with our request and we finally had to have the tobacco sent to a hardware firm who re-packed it for us as we desired.

Another and more costly packing was used on the order of some dredge-bucket pins. These pins, weighing almost 200 lb. apiece, were packed, ten together, in a heavy two-inch plank case, which made the weight over a ton to a box. Not only did we have to pay the custom duties on these boxes but we had to pay the extra tariff on river-steamers for the extra weight. This on boxes or crates weighing 500 kilo amounted to 25% extra; 1000 kilo to 50%, and so on up, in addition to the regular rate. These forged pins could have been shipped loose, saving all that.

It is well for exporting houses to understand the ocean tariffs in regard to space and weight extras, and purchasers should give the local river and transportation tariffs so that goods can be packed in packages of the most economical size, assuring the lowest rates. We ordered a lot of window and plate glass from a firm in the United States three times and out of over one hundred pieces we did not receive half a dozen pieces unbroken in the three shipments. We had carefully gone over the result of the arrival of each shipment in letters to the firm supplying the same, and even made suggestions as to the way we considered it best to pack the glass, but all to no purpose. Finally we placed the order with a German firm and received it without a single broken piece.

By the above examples I do not mean to advocate a light boxing or a sparing of packing material. It all depends on what is being sent. Some goods can be sent wrapped only in burlap when there is no danger of crushing or breaking; and if liable to be injured by water, further protection is obtained by using waterproof paper. But in the case of delicate machines or electrical apparatus, the utmost care must be taken in packing. One must have the idea constantly in mind what handling the goods will undergo before reaching their destination. The journey from the warehouse to the docks is usually not hard. Here the ships take the different boxes, crates, and parcels in rope-slings and drop them into the hold, often with quite a shock. If a light crate happens to be on the bottom, under heavy boxes, it is apt to be damaged. The storage on the voyage is not likely to produce much damage; but the unloading is again attended with danger. The captain is usually in a hurry to clear his hold and the slings are filled, hoisted, and dropped with all possible speed. At Puerto Colombia the goods from these slings are loaded immediately on freight-cars and run up to Barranquilla, a distance of 18 miles, to the custom-house. Here they are unloaded and inspected. When reloaded, they are taken in carts to the yards of the river-steamboat company and dropped off the carts upon the ground. And here it may be well to say that any sign in English, such as "Glass," "This Side Up," or "Handle With Care," is unintelligible, and totally disregarded. If in Spanish, it meets with but little more consideration. It is only by being on the spot and with constant nagging that you can in any way protect your goods. I do not mean that these signs should not be put on the cases; they should be inscribed in both languages, but the packing should be done with such skill that even after all possible hardships the articles enclosed will arrive safely at their destination. The loading on the river boat is all done by hand, using block and tackle or a steam-capstan. The smaller packages are dumped into the hold and rolled into place; the larger ones are put on deck or on barges to be towed. The voyage of 370 miles up the river is usually not hard on the cargo, except that some of the boxes on the barges may be thoroughly wetted and sometimes those in the hold are similarly treated. In the dry season all the

goods will be dumped on the bank if the boat is unable to reach its destination, to wait there until the river rises and the boat again reaches the spot. We had several experiences of the river coming up and flooding goods left on the bank high above low water, but not above the flood-level. When the goods reached us we were able to unload them by derrick and see that they were handled rightly. But the damage, if any, had been done before their arrival.

The best practice in the packing of small articles, it seems to me, is to put them in packages of around 100 to 150 pounds weight. These can be carried easily and the carriers are not given the incentive to drop them. In the packing of such articles as bolts the tendency is to put them in cases weighing from 300 to 400 lb. and these cases we often received badly damaged, or with some of the contents missing.

In this connection I am reminded of the cases of petty pilfering that used to annoy us, especially in the matter of food supplies. A can or two from a case would be missing. The condensed-milk cases suffered especially. Sometimes the cans would be punctured, the contents removed, and the can replaced. Often too the cans would be damaged in the rough treatment received and the contents spoiled. This might be due to the cases being too lightly constructed, allowing the cans too much movement. Especially was this true of the gallon-cans of fruit that often arrived in poor shape. We had to give up the use of these large cans and use the smaller sizes. However, if the exporter would have his fruit put up in heavier cans and more solidly constructed cases than are used for domestic consumption, this would not occur. The English are far ahead of us in putting up food supplies for tropical countries, in great measure due to the large trade they have had for many years with India. We have ordered dried fruits put up in sealed tins from one of the large New York houses and they came in screwed-top tins. The moisture and heat soon spoiled a good part of the contents.
